Suppose for a moment that t_1, t_2, t_3, are *all* known; then the equations being linear in y_1, y_2, y_3, these can be expressed rationally in terms of the coefficients and of t_1, t_2, t_3; that is, y_1, y_2, y_3 will be known. But observe further that y_1 is obtained as a function of t_1, t_2, t_3, symmetrical as regards t_2, t_3; it can therefore be expressed as a rational function of t_1 and of t_2+t_3, t_2t_3, and thence as a rational function of t_1 and of $t_1+t_2+t_3, t_1t_2+t_1t_3+t_2t_3, t_1t_2t_3$; but these last are symmetrical functions of the roots, and as such they are expressible rationally in terms of the coefficients; that is, y_1 will be expressed as a rational function of t_1 and of the coefficients; or t_1 (alone, not t_2 or t_3) being known, y_1 will be rationally determined.

24. We now consider the question of the algebraical solution of equations, or, more accurately, that of the *solution of equations by radicals.*

In the case of a quadric equation $x^2-px+q=0$, we can by the assistance of the sign $\sqrt{(\quad)}$ or $(\quad)^{\frac{1}{2}}$ find an expression for x as a two-valued function of the coefficients p, q such that substituting this value in the equation, the equation is thereby identically satisfied; it has been found that this expression is

$$x=\tfrac{1}{2}\{p+\sqrt{p^2-4q}\},$$

and the equation is on this account said to be algebraically solvable, or more accurately solvable by radicals. Or we may by writing $x= -\frac{1}{2}p+z$, reduce the equation to $z^2=\frac{1}{4}(p^2-4q)$, viz., to an equation of the form $z^2=a$; and in virtue of its being thus reducible we say that the original equation is solvable by radicals. And the question for an equation of any higher order, say of the order n, is, can we by means of radicals (that is by aid of the sign $\sqrt[m]{(\quad)}$ or $(\quad)^{\frac{1}{m}}$, using as many as we please of such signs and with any values of m) find an n-valued function (or any function) of the coefficients which substituted for x in the equation shall satisfy it identically?

It will be observed that the coefficients p, q.. are not explicitly considered as numbers, but even if they do denote numbers, the question whether a numerical equation admits of solution by radicals is wholly unconnected with the before-mentioned theorem of the existence of the n roots of such an equation. It does not even follow that in the case of a numerical equation solvable by radicals the algebraical solution gives the numerical solution, but this requires explanation. Consider first a numerical quadric equation with imaginary coefficients. In the formula $x=\frac{1}{2}(p\pm\sqrt{p^2-4q})$, substituting for p, q their given numerical values, we obtain for x an expression of the form $x=\alpha+\beta i\pm\sqrt{\gamma+\delta i}$, where $\alpha, \beta, \gamma, \delta$ are real numbers. This expression substituted for x in the quadric equation would satisfy it identically, and it is thus an algebraical solution; but there is no obvious *a priori* reason why $\sqrt{\gamma+\delta i}$ should have a value $=c+di$, where c and d are real numbers calculable by the extraction of a root or roots of real numbers; however the case is (what there was no *a priori* right to expect) that $\sqrt{\gamma+\delta i}$ has such a value calculable by means of the radical expressions $\sqrt{\{\sqrt{\gamma^2+\delta^2}\pm\gamma\}}$: and hence the algebraical solution of a numerical quadric equation does in every case give the numerical solution. The case of a numerical cubic equation will be considered presently.

25. A cubic equation can be solved by radicals. Taking for greater simplicity the cubic in the reduced form $x^3+qx-r=0$, and assuming $x=a+b$, this will be a solution if only $3ab=q$ and $a^3+b^3=r$, equations which give $(a^3-b^3)^2=r^2-\frac{4}{27}q^3$, a quadric equation solvable by radicals, and giving $a^3-b^3=\sqrt{r^2-\frac{4}{27}q^3}$, a two-valued function of the coefficients: combining this with $a^3+b^3=r$, we have $a^3=\frac{1}{2}(r+\sqrt{r^2-\frac{4}{27}q^3})$, a two-valued function: we then, have a by means of a cube root, viz.,

$$a=\sqrt[3]{\{\tfrac{1}{2}(r+\sqrt{r^2-\tfrac{4}{27}q^3})\}},$$

a six-valued function of the coefficients; but then, writing $q=\frac{b}{3a}$, we have, as may be shown, $a+b$, a three-valued function of the coefficients; and $x=a+b$ is the required solution by radicals. It would have been wrong to complete the solution by writing

$$b=\sqrt[3]{\{\tfrac{1}{2}(r-\sqrt{r^2-\tfrac{4}{27}q^3})\}},$$

for then $a+b$ would have been given as a 9-valued function having only 3 of its values roots, and the other 6 values being irrelevant. Observe that in this last process we make no use of the equation $3ab=q$, in its original form, but use only the derived equation $27a^3b^3=q^3$, implied in, but not implying, the original form.

An interesting variation of the solution is to write $x=ab(a+b)$, giving $a^3b^3(a^3+b^3)=r$ and $3a^3b^3=q$, or say $a^3+b^3=\frac{3r}{q}$, $a^3b^3=\frac{1}{3}q$; and consequently

$$a^3=\frac{\frac{3}{2}}{q}r+\sqrt{r^2-\tfrac{4}{27}q^3}),\ b^3=\frac{\frac{3}{2}}{q}r-\sqrt{r^2-\tfrac{4}{27}q^2}),$$

i. e., here a^3, b^3 are each of them a two-valued function. but as the only effect of altering the sign of the quadric radical is to interchange a^3, b^3, they may be regarded as eacn of them one-valued; a and b are each of them 3-valued (for observe that here only a^3b^3, not ab, is given); and $ab\ (a+b)$ thus is in appearance a 9-valued function; but it can easily be shown that it is (as it ought to be) only 3-valued.

In the case of a numerical cubic, even when the coefficients are real, substituting their values in the expression

$$x=\sqrt[3]{\{\tfrac{1}{2}(r+\sqrt{r^2-\tfrac{4}{27}q^3})\}}+\tfrac{1}{3}q\div\sqrt[3]{\{\tfrac{1}{2}(r+\sqrt{r^2-\tfrac{4}{27}q^3})\}},$$

this may depend on an expression of the form $\sqrt[3]{\gamma+\delta i}$ where γ and δ are real numbers (it will do so if $r^2-\frac{4}{27}q^3$ is a negative number), and then we *cannot* by the extraction of any root or roots of real positive numbers reduce $\sqrt[3]{\gamma+\delta i}$ to the form $c+di$, c and d real numbers; hence here the algebraical solution does *not* give the numerical solution, and we have here the so-called "irreducible case" of a cubic equation. By what precedes there is nothing in this that might not have been expected; the algebraical solution makes the solution depend on the extraction of the cube root of — a number, and there was no reason for expecting this to be a real number. It is well known that the case in question is that wherein the three roots of the numerical cubic equation are all real; if the roots are two imaginary, one real, then contrariwise the quantity under the cube root is real; and the algebraical solution gives the numerical one.

The irreducible case is solvable by a trigonometrical formula, but this is not a solution by radicals: it consists in effect in reducing the given numerical cubic (not to a cubic of the form $z^3=a$, solvable by the extraction of a cube root, but) to a cubic of the form $4x^3-3x=a$, corresponding to the equation $4\cos^3\theta-3\cos\theta=\cos3\theta$ which serves to determine $\cos\theta$ when $\cos3\theta$ is known. The theory is applicable to an algebraical cubic equation; say that such an equation, if it can be reduced to the form $4x^3-3x=a$, is solvable by "trisection"—then the general cubic equation is solvable by trisection.

26. A quartic equation is solvable by radicals: and it is to be remarked that the existence of such a solution depends on the existence of 3-valued functions such as $ab+cd$ of the four roots (a, b, c, d): by what precedes $ab+cd$ is the root of a cubic equation, which equation is solvable by radicals: hence $ab+cd$ can be found by radicals; and since $abcd$ is a given function, ab and cd can then be found by radicals. But by what precedes, if ab be known then any similar function, say $a+b$, is obtainable rationally; and then from the values of $a+b$ and ab we may by radicals obtain the value of a or b, that is, an expression for the root of the given quartic equation: the expression ultimately obtained is 4-valued, corresponding to the different values of the several radicals which enter therein, and we have thus the expression by radicals of each of the four roots of the quartic equation. But when the quartic is numerical the same thing happens as in the cubic, and the algebraical solution does not in every case give the numerical one.

It will be understood from the foregoing explanation as to the quartic how in the next following case, that of the quintic, the question of the solvability by radicals depends on the existence or non-existence of k-valued functions of the five roots (a, b, c, d, e); the fundamental theorem is the one already stated, a rational function of five letters, if it has less than 5, cannot have more than 2 values, that is, there are no 3-valued or 4-valued functions of 5 letters: and by reasoning depending in part upon this theorem, Abel (1824) showed that a general quintic equation is not solvable by radicals; and *a fortiori* the general equation of any order higher than 5 is not solvable by radicals.

27. The general theory of the solvability of an equation by radicals depends fundamentally on Vandermonde's remark (1770) that, supposing an equation is solvable by radicals, and that we have therefore an algebraical expression of x in terms of the coefficients, then, substituting for the coefficients their values in terms of the roots, the resulting expression must reduce itself to any one at pleasure of the roots $a, b, c \ldots$; thus in the case of the quadric equation, in the expression $x=\frac{1}{2}(p+\sqrt{p^2-4q})$, substituting for p and q their values, and observing that $(a+b)^2-4ab=(a-b)^2$, this becomes $x=\frac{1}{2}\{a+b+\sqrt{(a-b)^2}\}$, the value being a or b according as the radical is taken to be $+(a-b)$ or $-(a-b)$.

So in the cubic equation $x^3-px^2+qx-r=0$, if the roots are a, b, c, and if ω is used to denote an imaginary cube root of unity, $\omega^2+\omega+1=0$, then writing for shortness $p=a+b+c$, $\mathrm{L}=a+\omega b+\omega^2 c$, $\mathrm{M}=a+\omega^2 b+\omega c$, it is at once seen that LM, $\mathrm{L}^3+\mathrm{M}^3$, and therefore also $(\mathrm{L}^3-\mathrm{M}^3)^2$ are symmetrical functions of the roots, and consequently rational functions of the coefficients: hence

$$\tfrac{1}{2}\{\mathrm{L}^3+\mathrm{M}^3+\sqrt{\mathrm{L}^3-\mathrm{M}^3)^2}\}$$

is a rational function of the coefficients, which when these are replaced by their values as functions of the roots becomes, according to the sign given to the quadric radical, $=\mathrm{L}^3$ or M^3: taking it $=\mathrm{L}^3$, the cube root of the expression has the three values $\mathrm{L}, \omega\mathrm{L}, \omega^2\mathrm{L}$; and LM divided by the same cube root has therefore the values $\mathrm{M}, \omega^2\mathrm{M}, \omega\mathrm{M}$; whence finally the expression

$$\begin{aligned}&\tfrac{1}{3}[p+\sqrt[3]{\{\tfrac{1}{2}(\mathrm{L}^3+\mathrm{M}^3+\sqrt{(\mathrm{L}^3-\mathrm{M}^3)^2})\}}\\&+\mathrm{LM}\div\sqrt{\{\tfrac{1}{2}\mathrm{L}^3+\mathrm{M}^3+\sqrt{(\mathrm{L}^3-\mathrm{M}^3)^2})\}}]\end{aligned}$$

has the three values

$$\tfrac{1}{3}(p+\mathrm{L}+\mathrm{M}),\ \tfrac{1}{3}(p+\omega\mathrm{L}+\omega^2\mathrm{M}),\ \tfrac{1}{3}(p+\omega^2\mathrm{L}+\omega\mathrm{M});$$

that is, these are $=a, b, c$ respectively. If the value M^3 had been taken instead of L^3, then the expression would have had the same three values a, b, c. Comparing the solution given for the cubic $x^3+qx-r=0$, it will readily be seen that the two solutions are identical, and that the function $r^2-\frac{4}{27}q^3$ under the radical sign must (by aid of the relation $p=0$ which subsists in this case) reduce itself to $(\mathrm{L}^3-\mathrm{M}^3)^2$; it is only by each radical being equal to a rational function of the roots that the final expression *can* become equal to the roots a, b, c respectively.

28. The formulæ for the cubic were obtained by Lagrange (1770–71) from a different point of view. Upon examining and comparing the principal known methods for the solution of algebraical equations, he found that they all ultimately depended upon finding a "resolvent" equation of which the root is $a+\omega b+\omega^2 c+\omega^3 d+\ldots$, ω being an imaginary root of unity, of the same order as the equation; *e.g.*, for the cubic the root is $a+\omega b+\omega^2 c$, ω an imaginary cube root of unity. Evidently the method gives for L^3 a quadric equation, which is the "resolvent" equation in this particular case.

For a quartic the formulæ present themselves in a somewhat different form, by reason that 4 is not a prime number. Attempting to apply it to a quintic, we seek for the equation of which the root is $(a+\omega b+\omega^2 c+\omega^3 d+\omega^4 e)$, ω an imaginary fifth root of unity, or rather the fifth power thereof $(a+\omega b+\omega^2 c+\omega^3 d+\omega^4 e)^5$; this is a 24-valued function, but if we consider the four values corresponding to the roots of unity $\omega, \omega^2, \omega^3, \omega^4$, viz., the values

$$\begin{aligned}&(a+\omega\,b+\omega^2 c+\omega^3 d+\omega^4 e)^5,\\&(a+\omega^2 b+\omega^4 c+\omega\,d+\omega^3 e)^5,\\&(a+\omega^3 b+\omega\,c+\omega^4 d+\omega^2 e)^5,\\&(a+\omega^4 b+\omega^3 c+\omega^2 d+\omega\,e)^5,\end{aligned}$$

any symmetrical function of these, for instance their sum, is a six-valued function of the roots, and may therefore be determined by means of a sextic equation, the coefficients whereof are rational functions of the coefficients of the original quintic equation; the conclusion being that the solution of an equation of the fifth order is made to depend upon that of an equation of the sixth order. This is, of course, useless for the solution of the quintic equation, which, as already mentioned, does not admit of solution by radicals; but the equation of the sixth order, Lagrange's resolvent sextic, is very important, and is intimately connected with all the later investigations in the theory.

29. It is to be remarked, in regard to the question of solvability by radicals, that not only the coefficients are taken to be arbitrary, but it is assumed that they are represented each by a single letter, or say rather that they are not so expressed in terms of other arbitrary quantities as to make a solution possible. If the coefficients are not all arbitrary, for instance, if some of them are zero, a sextic equation might be of the form $x^6+bx^4+cx^2+d=0$, and so be solvable as a cubic; or if the coefficients of the sextic are given functions of the six arbitrary quantities a, b, c, d, e, f, such that the sextic is really of the form $(x^2+ax+b)(x^4+cx^3+dx^2+ex+f)=0$, then it breaks up into the equations $x^2+ax+b=0$, $x^4+cx^3+dx^2+ex+f=0$, and is consequently solvable by radicals; so also if the form is $(x-a)(x-b)(x-c)(x-d)(x-e)(x-f)=0$, then the equation is solvable by radicals,—in this extreme case rationally. Such cases of solvability are self-evident; but they are enough to show that the general theorem of the non-solvability by radicals of an equation of the fifth or any higher order does not in any wise exclude for such orders the existence of particular equations solvable by radicals, and there are, in fact, extensive classes of equations which are thus solvable; the binomial equations $x^n-1=0$ present an instance.

30. It has already been shown how the several roots of the equation $x^n-1=0$ can be expressed in the form $\cos\frac{2s\pi}{n}+i\sin\frac{2s\pi}{n}$, but the question is now that of the algebraical solution (or solution by radicals) of this equation. There is always a root $=1$; if ω be any other root, then obviously $\omega, \omega^2, \ldots \omega^{n-1}$ are all of them roots; x^n-1 contains the factor $x-1$, and it thus appears that $\omega, \omega^2, \ldots \omega^{n-1}$ are the $n-1$ roots of the equation

$$x^{n-1}+x^{n-2}+\ldots+x+1=0;$$

we have, of course, $\omega^{n-1}+\omega^{n-2}\ldots+\omega+1=0$.

It is proper to distinguish the cases n prime and n composite; and in the latter case there is a distinction according as the prime factors of n are simple or multiple. By way of illustration, suppose successively $n=15$ and $n-9$; in the former case, if a be an imaginary root of $x^3-1=0$ (or root of $x^2+x+1=0$), and β an imaginary root of $x^5-1=0$ (or root of $x^4+x^3+x^2+x+1=0$), then ω may be taken $=a\beta$; the successive powers thereof, $a\beta, a^2\beta^2, \beta^3, a\beta^4, a^2, \beta, a\beta^2, a^2\beta^3, \beta^4, a, a^2\beta, \beta^2, a\beta^3, a^2\beta^4$, are the roots of $x^{14}+x^{13}\ldots+x+1=0$; the solution thus depends on the solution of the equations $x^3-1=0$ and $x^5-1=0$. In the latter case, if a be an imaginary root of $x^3-1=0$ (or root of $x^2+x+1=0$), then the equation $x^9-1=0$ gives $x^3=1, a$, or a^2; $x^3=1$ gives $x=1, a$, or a^2; and the solution thus depends on the solution of the equations $x^3-1=0$, $x^3-a=0$, $x^3-a^2=0$. The first equation has the roots $1, a, a^2$; if β be a root of either of the others, say if $\beta^3=a$, then assuming $\omega=\beta$, the successive powers are $\beta, \beta^2, a, a\beta, a\beta^2, a^2, a^2\beta, a^2\beta^2$, which are the roots of the equation $x^8+x^7\ldots+x+1=0$.

It thus appears that the only case which need be considered is that of n a prime number, and writing (as is more usual) r in place of ω, we have $r, r^2, r^3, \ldots r^{n-1}$ as the $(n-1)$ roots of the reduced equation

$$r^{n-1}+r^{n-2}\ldots+r+1=0;$$

then not only $r^n-1=0$, but also $r^{n-1}+r^{n-2}\ldots+r+1=0$.

31. The process of solution due to Gauss (1801) depends essentially on the arrangement of the roots in a certain order, viz., not as above, with the indices of r in arithmetical progression, but with their indices in geometrical progression; the prime number n has a certain number of prime roots g, which are such that g^{n-1} is the lowest power of g, which is $\equiv 1$ to the modulus n; or, what is the same thing, that the series of powers $1, g, g^2 \ldots g^{n-2}$, each divided by n, leave (in a different order) the remainders $1, 2, 3 \ldots n-1$; hence giving to r in succession the indices $1, g, g^2 \ldots g^{n-2}$, we have, in a different order, the whole series of roots $r, r^2, r^3 \ldots r^{n-1}$.

In the most simple case, $n=5$, the equation to be solved is $x^4+x^3+x^2+x+1=0$; here 2 is a prime root of 5, and the order of the roots is r, r^2, r^4, r^3. The Gaussian process consists in forming an equation for determining the periods $\mathrm{P}_1, \mathrm{P}_2, =r+r^4$ and r^2+r^3 respectively,—these being such that the symmetrical functions $\mathrm{P}_1+\mathrm{P}_2$, $\mathrm{P}_1\mathrm{P}_2$ are rationally determinable: in fact $\mathrm{P}_1+\mathrm{P}_2=-1$, $\mathrm{P}_1\mathrm{P}_2=(r+r^4)(r^2+r^3), =r^3+r^4+r^6+r^7, =r^3+r^4+r+r^2, =-1$. P_1, P_2 are thus the roots of $u^2+u-1=0$; and taking them to be known, they are themselves broken up into subperiods, in the present case single terms, r and r^4 for P_1, r^2 and r^3 for P_2; the symmetrical functions of these are then rationally determined in terms of P_1 and P_2; thus $r+r^4=P_1$, $r.r^4=1$, or r, r^4 are the roots of $u^2-P_1u+1=0$. The mode of division is more clearly seen for a larger value of n; thus, for $n=7$ a prime root is $=3$, and the arrangement of the roots is $r, r^3, r^2, r^6, r^4, r^5$. We may form either three periods each of 2 terms, $P_1, P_2, P_3=r+r^6, r^3+r^4, r^2+r^5$ respectively; or else 2 periods each of 3 terms, $P_1, P_2=r+r^2+r^4, r^3+r^6+r^5$ respectively; in each case the symmetrical functions of the periods are rationally determinable: thus in the case of the two periods $P_1+P_2=-1$, $P_1P_2=3+r+r^2+r^3+r^4+r^5+r^6$, $=2$; and the periods being known the symmetrical functions of the several terms of each period are rationally determined in terms of the periods, thus $r+r^2+r^4=P_1$, $r.r^2+r.r^4+r^2.r^4=P_2$, $r.r^2.r^4=1$.

The theory was further developed by Lagrange (1808), who, applying his general process to the equation in question, $x^{n-1}+x^{n-2}\,..\,+x+1=0$ (the roots $a, b, c\,..$ being the several powers of r, the indices in geometrical progression as above), showed that the function $(a+\omega b+\omega^2c+\,..)^{n-}$ was in this case a given function of ω with integer coefficients. Reverting to the before-mentioned particular equation $x^4+x^3+x^2+x+1=0$, it is very interesting to compare the process of solution with that for the solution of the general quartic the roots whereof are a, b, c, d.

Take ω, a root of the equation $\omega^4-1=0$ (whence ω is $=1$, -1, i, or $-i$, at pleasure), and consider the expression

$$(a+\omega b+\omega^2c+\omega^3d)^4,$$

the developed value of this is

$$\begin{aligned}
= \quad & a^4+b^4+c^4+d^4+6(a^2c^2+b^2d^2)+12(a^2bd+b^2ca+c^2db+d^2ac)\\
+\omega\ & \{4(a^3b+b^3c+c^3+d^3a)+12(a^2cd+b^2da+c^2ab+d^2bc)\}\\
+\omega^2 & \{6(a^2b^2+b^2c^2+c^2d^2+d^2a^2)+4(a^3c+b^3d+c^3a+d^3b)+24abcd\}\\
+\omega^3 & \{4(a^3d+b^3a+c^3b+d^3c)+12(a^2bc+b^2cd+c^2da+d^2ab)\}
\end{aligned}$$

that is, this is a 6-valued function of a, b, c, d, the root of a sextic (which is, in fact, solvable by radicals; but this is not here material).

If, however, a, b, c, d denote the roots r, r^2, r^4, r^3 of the special equation, then the expression becomes

$$\begin{aligned}
& r^4+r^3+r+r^2+6(1+1)+12(r^2+r^4+r^3+r)\\
+\omega\ & \{4(1+1+1+1)+12(r^4+r^3+r+r^2)\}\\
+\omega^2 & \{6(r+r^2+r^4+r^3)+4(r^2+r^4+r^3+r)\}\\
+\omega^3 & \{4(r+r^2+r^4+r^3)+12(r^3+r+r^2+r^4)\}
\end{aligned}$$

viz., this is

$$=-1+4\omega+14\omega^2-16\omega^3,$$

a completely determined value. That is, we have

$$(r+\omega r^2+\omega^2r^4+\omega^3r^3)^4=-1+4\omega+14\omega^2-16\omega^3,$$

which result contains the solution of the equation. If $\omega=1$, we have $(r+r^2+r^4+r^3)^4=1$, which is right; if $\omega=-1$, then $(r+r^4-r^2-r^3)^4=25$; if $\omega=i$, then we have $\{r-r^4+i\,(r^2-r^3)\}^4=-15+20i$; and if $\omega=-i$, then $\{r-r^4-i\,(r^2-r^3)\}^4=-15-20i$; the solution may be completed without difficulty.

The result is perfectly general, thus:—n being a prime number, r a root of the equation $x^{n-1}+x^{n-2}\,....\,+x+1=0$, ω a root of $\omega^{n-1}-1=0$, and g a prime root of $g^{n-1}\equiv1$ (mod. n), then

$$(r+\omega r^g\ .\ .\ .\ .\ +\omega^{n-2}r^{g^{n-2}})^{n-1}$$

is a given function $M_0+M_1\omega\,...+M_{n-2}\omega^{n-2}$ with integer coefficients, and by the extraction of $(n-1)$th roots of this and similar expressions we ultimately obtain r in terms of ω, which is taken to be known; the equation $x^n-1=0$, n a prime number, is thus solvable by radicals. In particular, if $n-1$ be a power of 2, the solution (by either process) requires the extraction of square roots only; and it was thus that Gauss discovered that it was possible to construct geometrically the regular polygons of 17 sides and 257 sides respectively. Some interesting developments in regard to the theory were obtained by Jacobi (1837); see the memoir "Ueber die Kreistheilung, u.s.w.," *Crelle*, t. xxx. (1846).

The equation $x^{n-1}+\,..\,+x+1=0$ has been considered for its own sake, but it also serves as a speciman of a class of equations solvable by radicals, considered by Abel (1828), and since called Abelian equations, viz., for the Abelian equation of the order n, if x be any root, the roots are $x, \theta x, \theta^2x, \ldots \theta^{n-1}x$ (θx being a rational function of x, and $\theta^nx=x$); the theory is, in fact, very analogous to that of the above particular case. A more general theorem obtained by Abel is as follows:—If the roots of an equation of any order are connected together in such wise that *all* the roots can be expressed rationally in terms of any one of them, say x; if, moreover, θx, θ_1x being any two of the roots, we have $\theta\theta_1x=\theta_1\theta x$, the equation will be solvable algebraically. It is proper to refer also to Abel's definition of an *irreducible* equation:—an equation $\phi x=0$, the coefficients of which are rational functions of a certain number of known quantities $a, b, c\,..$, is called irreducible when it is impossible to express its roots by an equation of an inferior degree, the coefficients of which are also rational functions of $a, b, c\,...$ (or, what is the same thing, when ϕx does not break up into factors which are rational functions of $a, b, c\,..$). Abel applied his theory to the equations which present themselves in the division of the elliptic functions, but not to the modular equations.

32. But the theory of the algebraical solution of equations in its most complete form was established by Galois (born October, 1811, killed in a duel May, 1832; see his collected works, *Liouville*, t. xl., 1846). The definition of an irreducible equation resembles Abel's,—an equation is reducible when it admits of a rational divisor, irreducible in the contrary case; only the word *rational* is used in this extended sense that, in connection with the coefficients of the given equation, or with the irrational quantities (if any) whereof these are composed, he considers any number of other irrational quantities called "adjoint radicals," and he terms rational any rational function of the coefficients (or the irrationals whereof they are composed) and of thesé adjoint radicals; the epithet irreducible is thus taken either absolutely or in a relative sense, according to the system of adjoint radicals which are taken into account. For instance, the equation $x^4+x^3+x^2+x+1=0$; the left-hand side has here no rational divisor, and the equation is irreducible; but this function is $=(x^2+\tfrac{1}{2}x+1)^2-\tfrac{5}{4}x^2$, and it has thus the irrational divisors $x^2+\tfrac{1}{2}(1+\sqrt{5})x+1$, $x^2+\tfrac{1}{2}(1-\sqrt{5})x+1$; and these, if we *adjoin* the radical $\sqrt{5}$, are rational, and the equation is no longer irreducible. In the case of a given equation, assumed to be irreducible, the problem to solve the equation is, in fact, that of finding radicals by the adjunction of which the equation becomes reducible; for instance, the general quadric equation $x^2+px+q=0$ is irreducible, but it becomes reducible, breaking up into rational linear factors, when we adjoin the radical $\sqrt{\tfrac{1}{4}p^2-q}$.

The fundamental theorem is the Proposition I. of the "Mémoire sur les conditions de résolubilite des équations par radicaux;" viz., given an equation of which $a, b, c\,..$ are the m roots, there is always a group of permutations of the letters $a, b, c\,..$ possessed of the following properties:—

1. Every function of the roots invariable by the substitutions of the group is rationally known.

2. Reciprocally every rationally determinable function of the roots is invariable by the substitutions of the group.

Here by an invariable function is meant not only a function of which the form is invariable by the substitutions of the group, but further, one of which the value is invariable by these substitutions; for instance, if the equation be $\phi x=0$, then ϕx is a function of the roots invariable by any substitution whatever. And in saying that a function is rationally known, it is meant that its value is expressible rationally in terms of the coefficients and of the adjoint quantities.

For instance, in the case of a general equation, the group is simply the system of the $1.2.3\,...\,n$ permutations of all the roots, since, in this case, the only rationally determinable functions are the symmetric functions of the roots.

In the case of the equation $x^{n-1}\,...\,+x+1=0$, n a prime number, $a, b, c\,...\,k=r, r^g, r^{g^2}\,...\,r^{g^{n-2}}$, where g is a prime root of n, then the group is the cyclical group $abc\,...\,k$, $bc\,...\,ka$, $...\,kab\,...\,j$, that is, in this particular case the number of the permutations of the group is equal to the order of the equation.

This notion of the group of the original equation, or of the group of the equation as varied by the adjunction of a series of radicals, seems to be the fundamental one in Galois's theory. But the problem of solution by radicals, instead of being the sole object of the theory, appears as the first link of a long chain of questions relating to the transformation and classification of irrationals.

Returning to the question of solution by radicals, it will be readily understood that by the adjunction of a radical the group may be diminished; for instance, in the case of the general cubic, where the group is that of the six permutations, by the adjunction of the square root which enters into the solution, the group is reduced to *abc*, *bca*, *cab*; that is, it becomes possible to express rationally, in terms of the coefficients and of the adjoint square root, any function such as $a^2b+b^2c+c^2a$ which is not altered by the cyclical substitution a into b, b into c, c into a. And hence, to determine whether an equation of a given form is solvable by radicals, the course of investigation is to inquire whether, by the successive adjunction of radicals, it is possible to reduce the original group of the equation so as to make it ultimately consist of a single permutation.

The condition in order that an equation of a given prime order n may be solvable by radicals was in this way obtained —in the first instance in the form (scarcely intelligible without further explanation) that every function of the roots $x_1, x_2 \ldots x_n$, invariable by the substitutions x_{ak+b} for x_k, must be rationally known; and then in the equivalent form that the resolvent equation of the order $1 \,.\, 2 \,.\,.\, n-2$ must have a rational root. In particular, the condition in order that a quintic equation may be solvable, is that Lagrange's resolvent of the order 6 may have a rational factor, a result obtained from a direct investigation in a valuable memoir by E. Luther, *Crelle*, t. xxxiv. (1847).

Among other results demonstrated or announced by Galois may be mentioned those relating to the modular equations in the theory of elliptic functions; for the transformations of the orders 5, 7, 11, the modular equations of the orders 6, 8, 12 are depressible to the orders 5, 7, 11 respectively; but for the transformation, n a prime number greater than 11, the depression is impossible.

The general theory of Galois in regard to the solution of equations was completed, and some of the demonstrations supplied by Betti (1852). See also Serret's *Cours d'Algèbre supérieure*, 2d ed., 1854; 4th ed., 1877–78, in course of publication.

33. Returning to quintic equations, Jerrard (1835) established the theorem that the general quintic equation is by the extraction of only square and cubic roots reducible to the form $x^5+ax+b=0$, or what is the same thing, to $x^5+x+b=0$. The actual reduction by means of Tschirnhausen's theorem was effected by Hermite in connection with his elliptic-function solution of the quintic equation (1858) in a very elegant manner. It was shown by Cockle and Harley (1858–59) in connection with the Jerrardian form, and by Cayley (1861), that Lagrange's resolvent equation of the sixth order can be replaced by a more simple sextic equation occupying a like place in the theory.

The theory of the modular equations, more particularly for the case $n=5$, has been studied by Hermite, Kronecker, and Brioschi. In the case $n=5$, the modular equation of the order 6 depends, as already mentioned, on an equation of the order 5; and conversely the general quintic equation may be made to depend upon this modular equation of the order 6; that is, assuming the solution of this modular equation, we can solve (not by radicals) the general quintic equation; this is Hermite's solution of the general quintic equation by elliptic functions (1858); it is analogous to the before-mentioned trigonometrical solution of the cubic equation. The theory is reproduced and developed in Brioschi's memoir, "Ueber die Auflösung der Gleichungen vom fünften Grade," *Math. Annalen.* t. xiii. (1877–78).

34. The great modern work, reproducing the theories of Galois, and exhibiting the theory of algebraic equations as a whole, is Jordan's *Traité des Substitutions et des Equations Algébriques*, Paris, 1870. The work is divided into four books—book i., preliminary, relating to the theory of congruences; book ii. is in two chapters, the first relating to substitutions in general, the second to substitutions defined analytically, and chiefly to linear substitutions; book iii. has four chapters, the first discussing the principles of the general theory, the other three containing applications to algebra, geometry, and the theory of transcendents; lastly, book iv., divided into seven chapters, contains a determination of the general types of equations solvable by radicals, and a complete system of classification of these types. A glance through the index will show the vast extent which the theory has assumed, and the form of general conclusions arrived at; thus, in book iii., the algebraical applications comprise Abelian equations, equations of Galois; the geometrical ones comprise Hesse's equation, Clebsch's equations, lines on a quartic surface having a nodal line, singular points of Kummer's surface, lines on a cubic surface, problems of contact; the applications to the theory of transcendents comprise circular functions, elliptic functions (including division and the modular equation), hyperelliptic functions, solution of equations by transcendents. And on this last subject, solution of equations by transcendents, we may quote the result,—"the solution of the general equation of an order superior to five cannot be made to depend upon that of the equations for the division of the circular or elliptic functions;" and again (but with a reference to a possible case of exception), "the general equation cannot be solved by aid of the equations which give the division of the hyperelliptic functions into an odd number of parts."

(A. CA.)

EQUITES, an order of men in the commonwealth of Rome to which there is no exact parallel in modern times. Their origin goes back to the earliest period of Roman history. During the reign of the kings they appear to have been of noble birth, the younger branches of patrician families. This we may infer from the statement of Polybius (vi. 20), that the knights *now* are chosen according to fortune,—evidently intimating that their selection had previously depended on a different principle. Romulus is said to have divided them into three centuries or "hundreds," each century being chosen from one of the three old Roman tribes, the Ramnes, Tities, and Luceres. Both Tullus Hostilius and Tarquinius added to their number; but, according to Livy, it was Servius Tullius (576 B.C.) who first organized them into a distinct body and compelled the state to contribute annually to their maintenance. It is difficult to perceive in what way we are to explain the statement of Livy (i. 43), that ten thousand pounds of brass were given to each for the purchase of a horse,—an enormous sum when compared with that at which oxen and sheep were rated in the table of penalties. Every eques, of course, was bound to be provided with a good horse, and he may have been obliged to replace it if lost through any casualty in war. Its accoutrements, too, and a slave to take charge of it, were possibly all included in the sum. But whether, when the censor ordered the knight to sell his horse, it was the intention that the outfit money should be refunded to the state, we have no means of determining. Livy tells us also that the *æs hordearium* or barley-money supplied to each knight for the maintenance of his horse was obtained by a tax on widows and orphans. This certainly sounds strange, for it seems inconceivable that there should have been such a large number of rich widows; and even though the word *vidua* is explained to mean every single woman, maiden as well as widow, the difficulty still remains. Beyond the *hordearium* the knights received no pay.

In 400 B.C., during the siege of Veii, on account of the want of sufficient cavalry, those who possessed the requisite fortune offered to provide horses at their own expense. These new equites, distinguished as *equites equo privato*, in opposition to the *equites equo publico*, received regular pay, but, as by the very circumstances of their origin they had neither horse-money (*æs equestre*) nor barley-money (*æs hordearium*), they formed a distinct body from the old equites, and had no share in any of their peculiar privileges. In 303 B.C. the censors Q. Fabius and P. Decius established a law by which it was ordained that every fifth year a procession of the equites should take place, and that those who had misconducted themselves should be degraded from their rank. The procession (*equitum transvectio*) took place every year on the 15th of July (*idibus Quintilibus*), the anniversary of the battle of Lake Regillus. The knights in full equipment rode from the Temple of Honor in the south of the city through the Porta Capena and onwards past the temple of Castor and Pollux through the Forum to the Capitol. Their ranks were purged by the censors, before whom they filed past on foot. If the censor had no fault to find, he said to the eques, *traduc equum*, lead on your horse; but if he was dissatisfied he said, *vende equum*, sell your horse, and the eques ceased to belong to the order. This review bore the name of *equitum recognitio*, or, as the Greek writers translate it, *ἱππέων ἐπίσκεψις*. The equites evidently soon became a very powerful body in the state; yet in 186 B.C. we find it allowed as a reward to P. Æbutius that the censor should not assign him a public horse, and thereby compel him to serve as an eques against his will, proving that the duties must have been burdensome and regarded by many with distaste. In the later period of the republic the equites increased in power and consequence, and at the same time gradually ceased altogether to be what their name implied, the military service which they had formerly rendered being now obtained from allies and auxiliaries. To be an eques came to mean simply that a man was possessed of a certain amount of wealth without belonging to the senatorial order. The judicial functions were transferred from the senate to the body of equites by the Sempronian law, passed by C. Gracchus about 123 B.C.; and a short time afterwards they became the farmers of the public revenues, by which they were enabled to amass immense riches. They were deprived of their judicial powers by Sulla; but they now possessed too much influence in the state to be excluded from the higher and more dignified offices. After his death they were admitted to their former power, which, however, they shared with the senate. Towards the end of the republic, and under the emperors, the fortune requisite for an eques seems to have been four hundred sestertia, equal to about £3230 of our money; and even at this time knights' horses were furnished by the state, as we find by ancient inscriptions of that period.

The equites, who still in the reign of Augustus adhered for the most part to the use of the simple iron ring, had before the time of Pliny obtained the right of wearing the golden ring formerly distinctive of the senatorial order. Their dress was a tunic with a narrow purple stripe (*tunica angusticlavia*), in contrast to the senatorial tunic with a broad stripe (*tunica laticlavia*). In 67 B.C. a peculiar privilege was granted them by the Roscian law (*lex Roscia theatralis*), which reserved fourteen rows in the theatre behind the senatorial benches for their exclusive use.

Under the empire appears a class of equites distinguished as *singulares Augusti imperatoris*, which has been the subject of much debate. The epithet *singularis* is by some supposed to refer to their possession of a single horse, and by others it is regarded as indicative of their singular rank; but Henzen explains it as equivalent to *particularis*, because they were attached to the service of an individual. They formed a sort of body-guard to the emperor, were stationed in Rome, and only under peculiar circumstances were called to serve outside of the city. They appear to have consisted largely of foreigners, more especially from the north of Europe: the names of Germans, Batavians, Frisians, Frisævonians, Britons, Helvetians, Dalmatians, Bessians, Thracians, Rhætians, Pannonians, frequently occur. A considerable number are evidently freedmen who have adopted the name of the reigning emperor on their entrance into his service; but the advantages of the position also attracted not a few of the Roman citizens. At what time the corps was established is unknown: Henzen thinks it was by one of the Flavian emperors, as there is no mention of them under the Julian and Claudian families, but they were certainly in existence under Trajan. They disappear in the reign of Constantine. Their relation to the auxiliaries was similar to that of the prætorians to the Roman army proper. They were under the command of the prefects of the prætorium, and occupied two camps in the city,—one of which was at Torre Pignattara, where their monuments are frequently found.

Arch. di Roma*, 1850; Gomont, *Les chevaliers romains depuis Romulus jusqu'à Galba*, 1854; Belot, *Hist. des chevaliers romains depuis le temps des rois jusqu' au temps des Gracques*, 1867; and *Hist. des chev. rom. depuis le temps des Gracques jusqu'à la division de l'empire romain*, 1873; Ramsay, *Manual of Roman Antiquities*, 10th edition, 1876.

EQUITY in its most general sense means justice; in its most technical sense it means a system of law, or a body of connected legal principles, which have superseded or supplemented the common law on the ground of their intrinsic superiority. Aristotle (*Ethics*, bk. v. c. 10) defines equity as a better sort of justice, which corrects legal justice where the latter errs through being expressed in a universal form and not taking account of particular cases. When the law speaks universally, and something happens which is not according to the common course of events, it is right that the law should be modified in its application to that particular case, as the lawgiver himself would have done, if the case had been present to his mind. Accordingly the equitable man (ἐπιεικής) is he who does not push the law to its extreme, but, having legal justice on his side, is disposed to make allowances. Equity as thus described would correspond rather to the judicial discretion which modifies the administration of the law than to the antagonistic system which claims to supersede the law.

The part played by equity in the development of law is admirably illustrated in the well-known work of Sir Henry Maine on *Ancient Law*. Positive law, at least in progressive societies, is constantly tending to fall behind public opinion, and the expedients adopted for bringing it into harmony therewith are three, viz., legal fictions, equity, and statutory legislation. Equity here is defined to mean "any body of rules existing by the side of the original civil law, founded on distinct principles, and claiming incidentally to supersede the civil law in virtue of a superior sanctity inherent in those principles." It is thus different from legal fiction, by which a new rule is introduced surreptitiously, and under the pretence that no change has been made in the law, and from statutory legislation, in which the obligatory force of the rule is not supposed to depend upon its intrinsic fitness. The source of Roman equity was the fertile theory of natural law, or the law common to all nations. Even in the Institutes of Justinian the distinction is carefully drawn in the laws of a country between those which are peculiar to itself and those which natural reason appoints for all mankind. The connection in Roman law between the ideas of equity, nature, natural law, and the law common to all nations, and the influence of the Stoical philosophy on their development, are fully discussed in the third chapter of the work we have referred to. The agency by which these principles were introduced was the edicts of the prætor, an annual proclamation setting forth the manner in which the magistrate intended to adminster the law during his year of office. Each successive prætor adopted the edict of his predecessor, and added new equitable rules of his own, until the further growth of the irregular code was stopped by the Prætor Salvius Julianus in the reign of Hadrian.

The place of the prætor was occupied in English jurisprudence by the lord high chancellor. The real beginning of English equity is to be found in the custom of handing over to that officer, for adjudication, the complaints which were addressed to the king, praying for remedies beyond the reach of the common law. Over and above the authority delegated to the ordinary councils or courts, a reserve of judicial power was believed to reside in the king, which was invoked as of grace by the suitors who could not obtain relief from any inferior tribunal. To the chancellor, as already the head of the judicial system, these petitions were referred, although he was not at first the only officer through whom the prerogative of grace was administered. In the reign of Edward III. the equitable jurisdiction of the court appears to have been established. For some account of this tribunal see CHANCERY and CHANCELLOR. Its constitutional origin was analogous to that of the Star Chamber and the Court of Requests. The latter, in fact, was a minor court of equity attached to the lord privy seal as the Court of Chancery was to the chancellor. The successful assumption of extraordinary or equitable jurisdiction by the chancellor caused similar pretensions to be made by other officers and courts. "Not only the Court of Exchequer, whose functions were in a peculiar manner connected with royal authority, but the counties palatine of Chester, Lancaster, and Durham, the Court of Great Session in Wales, the universities, the city of London, the Cinque Ports, and other places silently assumed extraordinary jurisdiction similar to that exercised in the Court of Chancery." Even private persons, lords and ladies, affected to establish in their honors courts of equity.

English equity has one marked historical peculiarity, viz., that it established itself in a set of independent tribunals which remained in standing contrast to the ordinary courts for many hundred years. In Roman law the judge gave the preference to the equitable rule; in English law the equitable rule was enforced by a distinct set of judges. One cause of this separation was the rigid adherence to precedent on the part of the common law courts. Another was the jealousy prevailing in England against the principles of the Roman law on which English equity to a large extent was founded.

When a case of prerogative was referred to the chancellor in the reign of Edward III., he was required to grant such remedy as should be consonant to honesty (*honestas*). And honesty, conscience, and equity were said to be the fundamental principles of the court. The early chancellors were ecclesiastics, and under their influence not only moral principles, where these were not regarded by the common law, but also the equitable principles of the Roman law, were introduced into English jurisprudence. Between this point and the time when equity became settled as a portion of the legal system, having fixed principles of its own, various views of its nature seem to have prevailed. For a long time it was thought that precedents could have no place in equity, inasmuch as it professed in each case to do that which was just; and we find this view maintained by common lawyers after it had been abandoned by the professors of equity themselves. Mr. Spence, in his book on the *Equitable Jurisdiction of the Court of Chancery*, quotes a case in the reign of Charles II., in which Chief-Justice Vaughan said:—

> "I wonder to hear of citing of precedents in matter of equity, for if there be equity in a case, that equity is an universal truth, and there can be no precedent in it; so that in any precedent that can be produced, if it be the same with this case, the reason and equity is the same in itself; and if the precedent be not the same case with this, it is not to be cited."

But the Lord Keeper Bridgman answered:—

> "Certainly precedents are very necessary and useful to us, for in them we may find the reasons of the equity to guide us, and besides the authority of those who made them is much to be regarded. We shall suppose they did it upon great consideration and weighing of the matter, and it would be very strange and very ill if we should disturb and set aside what has been the course for a long series of times and ages."

Selden's description is well known:—"Equity is a roguish thing. 'Tis all one as if they should make the standard for measure the chancellor's foot." Lord Nottingham in 1676 reconciled the ancient theory and the established practice by saying that the conscience which guided the court was not the natural conscience of the man, but the civil and political conscience of the judge. The same tendency of equity to settle into a system of law is seen in the recognition of its limits—in the fact that it did not attempt in all cases to give a remedy when the rule of the common law was contrary to justice. Cases of hardship, which the early chancellors would certainly have relieved, were passed over by later judges, simply because no precedent could be found for their interference. The point at which the introduction of new principles of equity finally stopped is fixed by Sir Henry Maine in the chancellorship of Lord Eldon, who held that the doctrines of the court ought to be as well settled and made as uniform almost as those of the common law. From that time certainly equity, like common law, has professed to take its principles wholly from recorded decisions and statute law. The view (traceable no doubt to the Aristotelian definition) that equity mitigates the hardships of the law where the law errs through being framed in universals, is to be found in some of the earlier writings. Thus in the *Doctor and Student* it is said—

> "Law makers take heed to such things as may often come, and not to every particular case, for they could not though they would; therefore, in some cases it is necessary to leave the words of the law and follow that reason and justice requireth, and to that intent equity is ordained, that is to say, to temper and mitigate the rigor of the law.

And Lord Ellesmere said—

> "The cause why there is a Chancery is for that men's actions are so divers and infinite that it is impossible to make any general law which shall aptly meet with every particular act and not fail in some circumstances."

Modern equity, it need hardly be said, does not profess to soften the rigor of the law, or to correct the errors into which it falls by reason of its generality.

To give any account, even in outline, of the subject matter of equity within the necessary limits of this paper would be impossible. It will be sufficient to say here that the classification generally adopted by text-writers is based upon the relation of equity to the common law, of which some explanation is given above. Thus equitable jurisdiction is said to be exclusive, concurrent, or auxiliary. Equity has *exclusive* jurisdiction where it recognizes rights which are unknown to the common law. The most important example is trusts. Equity has *concurrent* jurisdiction in cases where the law recognized the right, but did not give adequate relief or did not give relief without circuity of action or some similar inconvenience. And equity has *auxiliary* jurisdiction when the machinery of the courts of law was unable to procure the necessary evidence.

"The evils of this double system of judicature," says the report of the late Judicature Commission, "and the confusion and conflict of jurisdiction to which it has led, have been long known and acknowledged." A partial attempt to meet the difficulty was made by several Acts of Parliament (passed after the reports of commissions appointed in 1850 and 1851), which enabled courts of law and equity both to exercise certain powers formerly peculiar to one or other of them. A more complete remedy was introduced by the Judicature Act, 1873, which consolidated the courts of law and equity, and ordered that law and equity should be administered concurrently according to the rules contained in the 26th section of the Act. The 25th section lays down certain legal principles in accordance with the general intention, and also declares that "generally in all matters not hereinbefore particularly mentioned, on which there is any conflict or variance between the rules of equity and the rules of the common law with reference to the same matter, the rules of equity shall prevail." (E. R.)

ERARD, SÉBASTIEN (1752–1831), a manufacturer of musical instruments, distinguished especially for the improvements he made upon the harp and the pianoforte, was born at Strasburg on the 4th April, 1752. While a boy he showed great aptitude for practical geometry and architectural drawing, and in the workshop of his father, who was an upholsterer, he found opportunity for the early exercise of his mechanical ingenuity. When he was sixteen his father died, and he removed to Paris, where he obtained employment with a harpsichord maker. Here his remarkable constructive skill, while it speedily excited the jealousy of his master and procured his dismissal, almost equally soon attracted the notice of musicians and musical instrument makers of eminence. Before he was twenty-five he set up in business for himself, his first workshop being a room in the hotel of the Duchesse de Villeroi, who gave him warm encouragement. Under her roof he constructed in 1780 his first pianoforte, which was also one of the first manufactured in France, the instruments used previous to that period in the houses of the Paris nobility having been imported from Germany and England. When heard in the *salon* of his patroness, it quickly secured for its maker such a reputation that he was soon overwhelmed with commissions. Finding assistance necessary, he sent for his brother, Jean Baptiste, in conjunction with whom he established in the Rue de Bourbon in the Faubourg St. Germain a piano manufactory, which in a few years became one of the most celebrated in Europe. On the outbreak of the Revolution he proceeded to London, where he established a factory similar to that in Paris. Returning to the French capital in 1796, he introduced soon afterwards grand pianofortes, made in the English fashion, with several improvements of his own. In 1808 he again visited London, where, two years later, he produced his first double-movement harp. He had previously made various improvements in the manufacture of harps, but the new instrument was an immense advance upon anything he had before produced, and obtained such a reputation that for some time he devoted himself exclusively to its manufacture. It has been said that in the year following his invention he made harps to the value of £25,000 In 1812 he returned to Paris, and continued to devote himself with unwearied industry and unfailing ingenuity to the further perfecting of the two instruments with which his name is associated. It is needless to enumerate all his improvements, especially as the more important of them must be described in any account of the harp and piano respectively. In 1823 he crowned his work by producing his model grand pianoforte with the double escapement. The action of these instruments is admirably adapted to convey every gradation of the player's touch to the strings, and on this account they have been much used by pianists of eminence. Erard died at Passy, on the 5th August, 1831.

ERASMUS, DESIDERIUS, was born at Rotterdam on the night of 27–8 October, and probably in the year 1466. The inscription on his statue, erected in his native place in 1622, names the year 1467; but the epitaph on his tombstone at Basel makes him 69 at the time of his death in July, 1536, a reckoning which might be compatible with either year, 1466 or 1467. The latter year is excluded by Erasmus's own statements, which, though inconsistent, agree on the whole best with the year 1466 (see *Ep.* 51, append.). His father's Christian name was Gerhard, of which Erasmus is meant for a Greek, and Desiderius for a Latin, rendering. He had no proper surname, not having been born in wedlock. His father provided for his education as long as he lived, placing him first as chorister in the cathedral school of Utrecht, and afterwards removing him to Deventer, of which school the celebrated teacher Alexander Hegius was at that time master. But Erasmus was too young—he left Deventer æt. 13—to have come much under the instruction of the head-master.

Both his father and his mother dying young, Erasmus was left to the care of three guardians, who endeavored to force him into a convent. They sent him for three years to a conventual preparatory school at Bois-le-duc (Hertogenbosch), and afterwards so far overcame his resistance that he entered upon the novitiate in a house of the regular canons of St. Augustine, at Stein, near Gouda. He made his profession here in 1486, æt. 19; and was afterwards ordained priest by the bishop of Utrecht. Erasmus had no vocation for the devotional exercises of convent life, and was disgusted with the society of the monks,—coarse, ignorant, and illiterate. His aspiration was to escape to some university where he might study. From the very first, the love of letters was the one ruling motive of his life. An unexpected chance brought him deliverance. Henri de Bergues, bishop of Cambray, took him to be his secretary. With the permission of the prior of Stein, and the consent of the general of the order and of the ordinary, the bishop of Utrecht, Erasmus left the convent. After a short stay with his new patron the bishop of Cambray, and with funds sparingly supplied by him, Erasmus entered the college of Montaigu in the university of Paris. Of the revolting economy of this college in respect of food and lodging he has left a graphic account in the *Colloquies* (Ichthyophagia): "I carried nothing away from it," he says, "but a body infected with disease, and a plentiful supply of vermin." Rabelais, it will be remembered, has recorded a similar experience.

To eke out his scanty means he took pupils. With one of these, Lord Mountjoy, he came to England in 1497. According to Anthony Wood, he spent three years, 1497 to 1499, in Oxford. Many of the biographers make him return to Paris in 1498; but the chronology of this part of Erasmus's life is confused. It is certain that he resided some time in Oxford, having a room in a small Augustinian house called St. Mary's College, in New-inn-hall Lane, and either there or in London made the acquaintance of the few Englishmen who were distinguished for learning, Colet, Grocyn, Linacer, Latimer, Sixtinus. In 1499 he was again in Paris, then at Orleans, then at St. Omer's in the Netherlands, and for the next five years he seems to have been continually on the move between France and Holland, his longest sojourn being at Louvain. In these years he had a hard struggle with poverty, supporting himself partly by pupils, partly by dedications. He wrote and delivered a Latin oration on the occasion of the reception of the archduke Philip at Brussels in 1504, for which he got a handsome fee. In April, 1506, we find him again in England, first in London, and becoming acquainted with More and Warham, then at Cambridge, performing the exercises for the divinity degree, and commencing B.D. "The Athenæ Cantabrigienses" of Cooper make him take the degree of D.D. at the university, but this is an error. His stay in England was not long, as he found opportunity to carry out a long cherished project of a journey to Italy. Want of funds had hitherto been the obstacle: "I have a longing to visit Italy," he wrote in 1498, "but it is not easy to fly without wings." He was engaged to escort the two sons of Baptista Boyer, physician to Henry VII., as far as Bologna. In September, 1506, he was at Turin, and took the degree of D.D. in that university. He passed the winter of 1506–7 at Bologna, where he was witness of the triumphal entry of Julius II., and where he made acquaintance with Paulus Bombasius and Scipio Carteromachus (Forteguerra). Here he obtained a papal dispensation permitting him to lay aside the dress of his order, though the story of his being mistaken for a plague-doctor in consequence of wearing it, is justly dismissed by Drummond as a pleasant fiction. He visited Venice, where he stayed some time, for the purpose of passing through the press of Aldus a second and greatly enlarged edition of his *Adagia*. Here he was domesticated in the house of Asulanus, and made the acquaintance of the circle of learned men who were clustered round the Aldine press,—Marcus Musurus, Aleander, Baptista Egnatius, etc.

In 1508 he removed to Padua, where he spent the winter as tutor to Alexander Stewart, natural son of James IV., king of Scotland. Father and son fell together, not long after, at Flodden. In the early spring of 1509 the tutor and pupil removed to Siena, and from Siena Erasmus went on to Rome. As his reputation had gone before him, he was received wherever he came with marks of distinction. But he learnt nothing from intercourse with the Italian literati; the Renaissance had already spent itself, and Erasmus complains "In Italia frigent studia, fervent bella." He had various offers of preferment, but a letter from Lord Mountjoy announcing the death of the king of England, April, 1509, and magnifying the favorable disposition of the young sovereign Henry VIII. towards Erasmus, and towards learning in general, determined his return to this country. From London, where he was the guest of Thomas More, and where he wrote his *Encomium Moriæ*, he moved to Cambridge, whither he was invited by John Fisher, bishop of Rochester, and lodged in Queen's College, of which Fisher was president. By Fisher's interest, he was appointed Lady Margaret's professor of divinity, and afterwards regius reader of Greek. From his mention of the grammars of Chrysoloras and of Gaza as the text-books on which he lectured, it may be inferred that the study of Greek was still in its infancy in that university. Gibbon's sarcasm that "Erasmus learned Greek at Oxford and taught it at Cambridge" (*Hist.*, ch. 66) has just this foundation.

The stipends of these chairs were small, and Erasmus refused to take fees from students mostly very poor. He lived upon presents from wealthy ecclesiastics. Archbishop Warham was his principal patron. Erasmus says, "He has given me a living worth a hundred nobles, and changed it at my request for a pension of one hundred crowns. Within these few years he has given me more than four hundred nobles without my asking; one day he gave me one hundred and fifty. From other bishops I have received more than one hundred. Lord Mountjoy has appointed me a pension of one hundred crowns." He got fifteen angels from Colet for a dedication. He says, in the *Compendium Vitæ*, that if the promises made to him had been performed he would have passed the rest of his days in England. But in this he perhaps deceived himself. At this period of his life, and till he was turned fifty, the agitation of locomotion, new places, and fresh faces was a necessity to him. An over-excited nervous sensibility was at the bottom of this feverish restlessness. In the autumn of 1513 he bade farewell to England, visited Lord Mountjoy at the Castle of Ham in Picardy, of which he was governor, and passed by the Rhine to Strasburg. Here he made the acquaintance of Wimpheling, Sebastian Brant, and the young Johann Sturm. He employed his time on board the tow-boat by which he leisurely ascended the river in correcting his "Commentarii de duplici copia," etc., for a new edition. To Basel, which was to be the home of his old age, he was attracted by the reputation of its press. But he met with such a hearty welcome from Froben and Amerbach, and found so agreeable a circle of men of learning, that he passed the whole winter 1514–15 here. The bishop of Basel, Christoph von Utenheim, was so much pleased with him that he sought to domesticate him in his house; he made the acquaintance of Zwingli and of Hans Holbein, and drew round him a circle of young students full of ardor for learning, and consequently of admiration for Erasmus—Glareanus, Œcolampadius, Beer, Myconius, Sapidus, and, above all, Beatus Rhenanus, who became his attached disciple and biographer.

Though from this time forward Basel became the centre of occupation and interest for Erasmus, yet for the next seven years he was in constant movement, from Basel to Flanders, thence to England in 1517, and back again to Basel. Offers of church preferment in various countries continued to be made to him. But his circumstances had improved so much, by pensions, the presents which were showered upon him, and the sale of his books, that he was now in a position to refuse all proposals which would have interfered with his cherished independence. Aware how necessary it was, if he would maintain his literary supremacy, to keep on good terms with the powerful in church and state, and therefore cautious not to give offence in word or act, he was yet most anxious to avoid dependence on any individual. It suited him to be always competed for, and never to sell himself. The general ardor for the restoration of the arts and of learning created an aristocratic public, of which Erasmus was supreme pontiff. Luther spoke to the people and the ignorant; Erasmus had the ear of the educated class. His friends and admirers were distributed over all the countries of Europe, and presents were continually arriving from small as well as great, from a donation of 200 florins, made by Pope Clement VII., down to sweetmeats and comfits contributed by the nuns of Cologne (*Ep.* 666). From England, in particular, he continued to receive supplies of money. In the last year of his life, Cromwell sent him 20 angels, and Archbishop Cranmer 18. Though Erasmus led a very hard-working and far from luxurious life, and had no extravagant habits, yet he could not live upon little. The excessive delicacy of his constitution exacted some unusual indulgences. He could not bear the iron stoves of Germany, and required an open fireplace, or a porcelain stove in the room in which he worked. He was afflicted with the stone, and obliged to be particular as to the wine he drank. The white wines of Baden or the Rhine did not suit him; he could only drink those of Burgundy or Franche-Comté. No more acceptable present could be offered him than a cask of the light-red wine of the Jura. He could neither eat nor bear the smell of fish. "His heart," he said, "was Catholic, but his stomach was Lutheran." For his constant journeys he required two horses, one for himself and one for his attendant. And though he was almost always found in horse-flesh by his friends, the keep had to be paid for. For his literary labors and his extensive correspondence he required one or more amanuenses. He often had occasion, on his own business, or on that of Froben's press, to send special couriers to a distance, employing them by the way in collecting the free gifts of his tributaries.

Precarious as these means of subsistence seem, he preferred the independence thus obtained to an assured position which would have involved obligations to a patron or professional duties which his weak health would have made onerous. He accepted the diploma of D.D. from the theological faculty at Louvain, but declined an offered professorship, saying "he did not like teaching." The duke of Bavaria offered to meet this objection by dispensing with teaching, if he would only reside, and would have named him on these terms to a chair in his new university of Ingolstadt, with a salary of 200 ducats, and the reversion of one or more prebendal stalls. The archduke Ferdinand offered a pension of 400 florins, if he would only come to reside at Vienna. Adrian VI. offered him a deanery (*Ep.* 859), but the offer seems to have been of a possible and not an actual deanery. Offers, flattering but equally vague, were made from France, on the part of the bishop of Bayeux, and even of Francis I. "Invitor amplissimis conditionibus; offeruntur dignitates et episcopatus; rex essem si juvenis essem" (*Ep.* 735). Erasmus declined all, and about the end of the year 1520 settled permanently at Basel, in the capacity of general editor and literary adviser of Froben's press. He had a house of his own in Louvain, and as a subject of the emperor, and attached to his court by a pension, it would have been convenient to him to have fixed his residence there. But the bigotry of the Flemish clergy, and the monkish atmosphere of the university of Louvain, overrun with Dominicans and Franciscans, united for once in their enmity to the new classical learning, inclined Erasmus to seek a more congenial home in Basel. Here a freer spirit reigned, and here he had already formed several fast friendships. But that which had most influence upon his choice was the fact that Basel had been made, by two enterprising publishers, Froben and Johann Amerbach, the centre of the German book-trade. The arrival of Erasmus was an event in Basel. He had a public reception, and received addresses on the part of the bishop and clergy, the municipality, and the university. But to Froben his arrival was the advent of the very man whom he had long wanted. Froben's enterprise, united with Erasmus's editorial skill, raised the press of Basel, for a time, to be the most important in Europe. The death of Froben in 1527, the final separation of Basel from the empire, the wreck of learning in the religious disputes, and the cheap paper and scamped work of the Frankfort presses, gradually withdrew the trade from Basel. But during the eight years of Erasmus's co-operation the Froben press took the lead of all the presses in Europe, both in the standard value of the works published and in style of typographical execution. Like some other publishers who preferred reputation to returns in money, Froben died poor, and his impressions never reached the splendor afterwards attained by those of the Estiennes, or of Plantin. The series of the Fathers alone contains Jerome (1516–18), Cyprian (1520), Pseudo-Arnobius (1522), Athanasius (Latin, 1522), Hilarius (1523), Irenæus (Latin, 1526), Ambrose (1527), Augustine (1528), Epiphanius (1529), Chrysostom on St. Matthew (Latin, 1530), Basil (Greek, 1532, the first Greek author printed in Germany), and Origen (Latin, 1536). In these editions, partly texts, partly translations, it is impossible to determine the respective shares of Erasmus and his many helpers. The prefaces and dedications are all written by him, and some of them, as that to the Hilarius, are of importance for the history as well of the times as of Erasmus himself. Of his most important edition, that of the Greek text of the New Testament, something will be said further on.

In this "mill," as he calls it, Erasmus continued to grind for eight years, from his 53d to his 61st year, getting through in that time an amount of literary labor to which most men in robust health would scarcely have proved equal. Besides his work as editor, he was always writing himself some book or pamphlet called for by the event of the day, some general fray in which he was compelled to mingle, or some personal assault which it was necessary to repel. He was himself painfully conscious how much his reputation as a writer was damaged by this extempore production. "An author," he says, "should handle with deliberate care the subject which he has selected, should keep his work long by him and retouch it many times before it sees the light. These things it has never been my good fortune to be able to do. Accident has determined my subject for me. I have written on without stopping, and published with such precipitation that changed circumstances have often compelled entire re-writing in the second edition" (*Ep. ad Botzhem.*). He was the object of those solicitations which always beset the author whose name upon the title-page assures the sale of a book. He was besieged for dedications, and as every dedication meant a present proportioned to the circumstances of the dedicatee, there was a natural temptation to be lavish of them. Add to this a correspondence so extensive as to require him at times to write forty letters in one day. "I receive daily," he writes, "letters from remote parts, from kings, princes, prelates, and men of learning, and even from persons of whose existence I was ignorant." His day was thus one of incessant mental activity, and he had acquired the power of working with such rapidity that J. C. Scaliger, one of his detractors, says (*Orat. 2 pro Cicerone*) that he had been told by Aldus that Erasmus did more work in one day than others did in two. Under the heading "Herculei Labores," in *The Adagia*, he hints at the immense labor which this compilation had cost him. But hard work was so far from breeding a distaste for his occupation, that reading and writing grew even more delightful to him (literarum assiduitas non modo mihi fastidium non parit, sed voluptatem; crescit scribendo scribendi studium).

In 1527 Johann Froben died, and the disturbances at Basel, occasioned by the zealots for the religious revolution which was in progress throughout Switzerland, began to make Erasmus desirous of changing his residence. He selected Freiburg in the Breisgau, as a city which was still in the dominion of the emperor, and was free from religious dissension. Thither he removed in April, 1529. He was received with public marks of respect by the authorities, who granted him the use of an unfinished residence which had been begun to be built for the late emperor Maximilian. Erasmus proposed only to remain at Freiburg for a few months, but found the place so suited to his habits that he bought a house of his own, and remained there six years. A desire for change of air—he fancied Freiburg was damp,—rumors of a new war with France, and the necessity of seeing his *Ecclesiastes* through the press, took him back to Basel in 1535. He lived now a very retired life, and saw only a small circle of intimate friends. It was now that a last attempt was made by the papal court to enlist him in some public way against the Reformation. On the election of Paul III. in 1534, he had, as usual, sent the new pope a congratulatory letter. After his arrival in Basel, he received a complimentary answer, together with the nomination to the deanery of Deventer, the income of which was reckoned at 1500 ducats. This nomination was accompanied with an intimation that more was in store for him, and that steps would be taken to provide for him the income, viz., 3000 ducats, which was necessary to qualify for the cardinal's hat. But Erasmus was even less disposed now than he had been before to barter his reputation for honors. His health had been for some years gradually declining, and disease in the shape of gout gaining upon him. In the winter of 1535–6, he was confined entirely to his chamber, many days to his bed. Though thus afflicted he never ceased his literary activity, dictating his tract *On the Purity of the Church*, and revising the sheets of a translation of Origen which was passing through Froben's press. His last letter is dated 28th June, 1536, and subscribed "Eras. Rot. ægra manu.". "I have never been so ill in my life before as I am now,—for many days unable even to read." Dysentery setting in carried him off 12th July, 1536, in his 69th year.

By his will, now preserved in the library at Basel, he left what he had to leave, with the exception of some legacies, to Boniface Amerbach, Johann Froben's son-in-law, partly for himself, partly in trust for the benefit of the aged and infirm, or to be spent in portioning young girls and in educating young men of promise. He left none of the usual legacies for masses or other clerical purposes, and was not attended by any priest or confessor in his last moments.

Erasmus's features are familiar to all, from Holbein's many portraits or their copies. Beatus Rhenanus, "Summus Erasmi observator," as he is called by De Thou, describes his person thus:—"In stature not tall, but not noticeably short; in figure well built and graceful; of an extremely delicate constitution, sensitive to the slightest changes of climate, food, or drink. After middle life he suffered from the stone, not to mention the common plague of studious men, an irritable mucous membrane. His complexion was fair; light blue eyes, and yellowish hair. Though his voice was weak, his enunciation was distinct; the expression of his face cheerful; his manner and conversation polished, affable, even charming." It was this delicacy of stomach, and not pampered appetite, that made him loathe fish, and be fastidious as to his wine. His highly nervous organization made his feelings acute, and his brain incessantly active. Through his ready sympathy with all forms of life and character, his attention was always alive. The active movement of his spirit spent itself, not in following out its own trains of thought, but in outward observation. No man was ever less introspective, and though he talks much of himself, his egotism is the genial egotism which takes the world into its confidence, not the selfish egotism which feels no interest but in its own woes. He says of himself, and justly, "that he was incapable of dissimulation" (*Ep.* 1152). There is nothing behind, no pose, no scenic effect. It may be said of his letters that in them "tota patet vita senis." His nature was flexible without being faultily weak. He has many moods, and each mood imprints itself in turn on his words. Hence, on a superficial view, Erasmus is set down as the most inconsistent of men. Further acquaintance makes us feel a unity of character underlying this susceptibility to the impressions of the moment. His seeming inconsistencies are reconciled to apprehension, not by a formula of the intellect, but by the many-sidedness of a highly impressible nature. In the words of Nisard, Erasmus was one of those "dont la gloire a été de beaucoup comprendre, et d'affirmer peu."

This equal openness to every vibration of the environment is the key to all Erasmus's acts and words, and among them to the middle attitude which he took up towards the great religious conflict of his time. The reproaches of party assailed him in his life-time, and have continued to be heaped upon his memory. He was loudly accused by ths Catholics of collusion with the enemies of the faith. His powerful friends, the pope, Wolsey, Henry VIII., the emperor, called upon him to declare against Luther. Theological historians from that time forward have perpetuated the indictment that Erasmus sided with neither party in the struggle for religious truth. The most moderate form of the censure presents him in the odious light of a trimmer: the vulgar and venomous assailant is sure that Erasmus was a Protestant at heart, but withheld the avowal that he might not forfeit the worldly advantages he enjoyed as a Catholic. When by study of his writings we come to know Erasmus intimately, there is revealed to us one of those natures to which partisanship is an impossibility. It was not timidity or weakness which kept Erasmus neutral, but the reasonableness of his nature. It was not only that his intellect revolted against the narrowness of party, his whole being repudiated its clamorous and vulgar excesses. As he loathed fish, so he loathed clerical fanaticism. Himself a Catholic priest,—"the glory of the priesthood and the shame"—the tone of the orthodox clergy was distasteful to him; the ignorant hostility to classical learning which reigned in their colleges and convents disgusted him. In common with all the learned men of his age, he wished to see the power of the clergy broken, as that of an obscurantist army arrayed against light. He had employed all his resources of wit and satire against the priests and monks, and the superstitions in which they traded, long before Luther's name was heard of. The motto which was already current in his life-time, "that Erasmus laid the egg and Luther hatched it," is so far true, and no more. Erasmus would have suppressed the monasteries, put an end to the domination of the clergy, and swept away scandalous and profitable abuses, but to attack the church or remould received theology was far from his thoughts. And when out of Luther's revolt there arose a new fanaticism—that of evangelism, Erasmus recoiled from the violence of the new preachers. "Is it for this," he writes to Melanchthon (*Ep.* 703), "that we have shaken off bishops and parties, that we may come under the yoke of such madmen as Otto and Farel?" Passages have been collected, and it is an easy task, from the writings of Erasmus to prove that he shared the doctrines of the Reformers. Passages equally strong might be culled to show that he repudiated them. The truth is that theological questions in themselves had no attraction for him. And when a theological position was emphasized by party passion it became odious to him. In 1521 he writes (*Ep.* 572) that he had not yet had time to read Luther's pamphlets, so offensive to his refined taste were their coarse vulgarity and exaggerated tone, as he had found on looking into them. In the words of Drummond, "Erasmus was in his own age the apostle of common sense and of rational religion. He did not care for dogma, and accordingly the dogmas of Rome, which had the consent of the Christian world, were in his eyes preferable to the dogmas of Protestantism. . . . From the beginning to the end of his career he remained true to the purpose of his life, which was to fight the battle of sound learning and plain common sense against the powers of ignorance and superstition, and amid all the convulsions of that period he never once lost his mental balance."

Erasmus is accused of indifference. But he was far from indifferent to the progress of the revolution. He was keenly alive to its pernicious influence on the cherished interest of his life, the cause of learning. "I abhor the evangelics, because it is through them that literature is everywhere declining, and upon the point of perishing." He had been born with the hopes of the Renaissance, with its anticipation of a new Augustan age, and had seen this fair promise blighted by the irruption of a new horde of theological polemics, worse than the old scholastics, inasmuch as they were revolutionary instead of conservative. Erasmus never flouted at religion, nor even at theology as such, but only at blind and intemperate theologians.

But though Erasmus while lashing theologians respected theology, he did not cultivate it. He barely acquiesced in church dogma without being compelled to investigate it. His mind had no metaphysical inclination; he was a man of letters, with a general tendency to rational views on every subject which came under his pen. His was not the mind to originate, like Calvin, a new scheme of Christian thought. He is at his weakest in defending free will against Luther, and indeed he can hardly be said to enter on the metaphysical question. He treats the dispute entirely from the outside. It is impossible in reading Erasmus not to be reminded of the rationalist of the 18th century. Erasmus has been called the "Voltaire of the Renaissance." But there is a vast difference in the relations in which they respectively stood to the church and to Christianity. Voltaire, though he did not originate, yet adopted a moral and religious scheme which he sought to substitute for the church tradition. He waged war, not only against the clergy, but against the church and its sovereigns. Erasmus drew the line at the first of these. He was not an anticipation of the 18th century; he was the man of his age, as Voltaire of his; though Erasmus did not intend it, he undoubtedly shook the ecclesiastical edifice in all its parts; and, as Melchior Adamus says of him, "pontifici Romano plus nocuit jocando, quam Lutherus stomachando."

But if Erasmus was unlike the 18th century rationalist in that he did not declare war against the church, but remained a Catholic and mourned the disruption, he was yet a true rationalist in principle. The principle that reason is the one only guide of life, the supreme arbiter of all questions, politics and religion included, has its earliest and most complete exemplar in Erasmus. He does not dogmatically denounce the rights of reason, but he practically exercises them. Along with the charm of style, the great attraction of the writings of Erasmus is this unconscious freedom by which they are pervaded.

It must excite our surprise that one who used his pen so freely should have escaped the pains and penalties which invariably overtook minor offenders in the same kind. For it was not only against the clergy and the monks that he kept up a ceaseless stream of satiric raillery; he treated nobles, princes, and kings with equal freedom. No 18th-century republican has used stronger language than has this pensioner of Charles V. "The people build cities, princes pull them down; the industry of the citizens creates wealth for rapacious lords to plunder; plebeian magistrates pass good laws for kings to violate; the people love peace, and their rulers stir up war." Such outbursts are frequent in one of his most popular books, *The Adagia.* These freedoms are part cause of Erasmus's popularity. He was here in sympathy with the secret sore of his age, and gave utterance to what all felt but none dared to whisper but he. It marks the difference between 1513 and 1669 that, in a reprint of the *Julius Exclusus* published in 1669 at Oxford, it was thought necessary to leave out a sentence in which the writer of that dialogue, supposed by the editor to be Erasmus, asserts the right of states to deprive and punish bad kings. It is difficult to say to what we are to ascribe his immunity from painful consequences. We have to remember that he was removed from the scene early (1536) in the reaction, before force was fully organized for the suppression of the revolution. And his popular works, *The Adagia* (1500), *The Colloquies* (1521), had established themselves as standard books in the more easy-going age, when power, secure in its unchallenged strength, could afford to laugh with the laughers at itself. At the date of his death (1536), the Catholic revival, with its fell antipathy to art and letters, was only in its infancy; and when times became dangerous, Erasmus cautiously declined to venture out of the protection of the empire, refusing repeated invitations to Italy and to France. "I had thought of going to Besançon," he said, "ne non essem in ditione Cæsaris" (*Ep.* 1299). In Italy a Bembo and a Sadoleto wrote a purer Latin than Erasmus, but contented themselves with pretty phrases, and were careful to touch no living chord of feeling. In France it was necessary for a Rabelais to hide his free-thinking under a disguise of revolting and unintelligible jargon. It was only in the empire that such liberty of speech as Erasmus used was practicable, and in the empire Erasmus passed for a moderate man. Upon the strength of an established character for moderation he enjoyed an exceptional license for the utterance of unwelcome truths; and in spite of his flings at the rich and powerful, he remained through life a privileged person with them. No noble except Eppendorf, young and crack-brained, ever attempted to call him seriously to account for his gibes.

But though the men of the keys and the sword let him go his way unmolested, it was otherwise with his brethren of the pen. A man who is always launching opinions must expect to be retorted on. And when these judgments were winged by epigram, and weighted by the name of Erasmus, who stood at the head of letters, a wide-spread exasperation was the consequence. Mr. Disraeli has not noticed Erasmus in his *Quarrels of Authors*, perhaps because Erasmus's quarrels would require a volume to themselves. "So thin-skinned that a fly would draw blood," as the prince of Carpi expressed it, he could not himself restrain his pen from sarcasm. He forgot that though it is safe to lash the dunces, he could not with equal impunity sneer at those who, though they might not have the ear of the public as he had, could yet contradict and call names. And when literary jealousy was complicated with theological differences, as in the case of the free-thinkers, or with French vanity, as in that of Budæus, the cause of the enemy was espoused by a party and a nation. The quarrel with Budæus was strictly a national one. Cosmopolitan as Erasmus was, to the French literati he was still the Teuton. Dolet calls him "enemy of Cicero, and jealous detractor of the French name." The only contemporary name which could approach to a rivalry with his was that of Budæus (Budé), who was exactly contemporary, having been born in the same year as Erasmus. Rivals in fame, they were unlike in accomplishment, each having the quality which the other wanted. Budæus, though a Frenchman, knew Greek well; Erasmus, though a Dutchman, very imperfectly. But the Frenchman Budæus wrote an execrable Latin style, unreadable then as now, while the Teuton Erasmus charmed the reading world with a style which, though far from good Latin, is the most delightful which the Renaissance has left us.

The style of Erasmus is, considered as Latin, incorrect, sometimes even barbarous, and far removed from any classical model. But it has qualities far above purity. The best Italian Latin is but an echo and an imitation; like the painted glass which we put in our churches, it is an anachronism. Bembo, Sadoleto, and the rest write purely in a dead language. Erasmus's Latin was a living and spoken tongue. Though Erasmus had passed nearly all his life in England, France, and Germany, he spoke not one of those three languages. His conversation was Latin; and the language in which he talked about common things he wrote. Hence the spontaneity and naturalness of his page, its flavor of life and not of books. He writes from himself, and not out of Cicero. Hence, too, he spoiled nothing by anxious revision in terror lest some phrase not of the golden age should escape from his pen. He confesses apologetically to Longolius (*Ep.* 402) that it was his habit to extemporize all he wrote, and that this habit was incorrigible; "effundo verius quam scribo omnia." But he was quite alive to the beauty of the Ciceronian periods of Bembo, Sadoleto, and Julius von Pflug, whom he calls "the three happiest stylists of our day" (*Ep.* 1370), and "would learn to imitate them, but he is too old." He complains that much reading of the works of St. Jerome had spoiled his Latin; but, as Scaliger says (*Scalig*^{a} *2*^{a}), "Erasmus's language is better than St. Jerome's." The same critic, however, thought Erasmus would have done better "if he had kept more closely to the classical models."

In the annals of classical learning Erasmus may be regarded as constituting an intermediate stage between the humanists of the Latin Renaissance and the learned men of the age of Greek scholarship, between Politiano and Joseph Scaliger. Erasmus, though justly styled by Muretus (*Varr. Lectt.* 7, 15), "eruditus sane vir, ac multæ lectionis," was not a "learned" man in the special sense of the word,—not an "érudit." He was more than this; he was the "man of letters,"—he first who had appeared in Europe since the fall of the Roman empire. His acquirements were vast, and they were all brought to bear upon the life of his day. He did not make a study apart of antiquity for its own sake, but used it as an instrument of culture. He did not worship, imitate, and reproduce the classics, like the Latin humanists who preceded him; he did not master them and reduce them to a special science, as did the French Hellenists who succeeded him. He edited many authors, it is true, but he had neither the means of forming a text, nor did he attempt to do so. In editing a father, or a classic, he had in view the practical utility of the general reader, not the accuracy required by the guild of scholars. "His Jerome," says J. Scaliger, "is full of sad blunders" (*Scalig*^{a} *2*^{a}). Even Julien Garnier could discover that Erasmus "falls in his haste into grievous error in his Latin version of St. Basil, though his Latinity is superior to that of the other translators" (Pref. in *Opp. St. Bas.*, 1721). It must be remembered that the commercial interests of Froben's press led to the introduction of Erasmus's name on many a title-page when he had little to do with the book, *e.g*, the Latin *Josephus* of 1534, to which Erasmus only contributed one translation of 14 pages; or the *Aristotle* of 1531, of which Simon Grynæus seems to have been the real editor. Where Erasmus excelled was in prefaces,—not philological introductions to each author, but spirited appeals to the interest of the general reader, showing how an ancient book might be made to minister to modern spiritual demands.

It has been the fate of Erasmus, as of so many great writers, to be best known to posterity by one of his slightest works. Those who have read nothing else of Erasmus have read his *Colloquies*. And a wider circle still, who would not care to read the text of the *Praise of Folly*, know of the book, because of the Holbein illustrations, which have preserved in general remembrance a Latin *jeu-d'-esprit* which would otherwise have only been consulted by the curious. But Erasmus himself complained of "the caprice of fortune," which had made his *Colloquies* his most popular work, a "book full of foolish things, bad Latin, and solecisms" (*Ep. ad. Botz.*). The *Encomium Moriæ* (Praise of Folly) was composed during his journey from Italy, and written out from his notes in seven days during his stay in Thomas More's house in London. It was not destined for publication, but a copy found its way into the hands of the printers Badius at Paris, and came out in 1512. Within a few months seven editions were called for, and Froben's reprint of 1515, consisting of 1800 copies, was sold in a few weeks. Milton, in 1628, speaks of it as being "in every one's hands" at Cambridge.

Of Erasmus's works, mostly hasty pamphlets, squibs, or personal explanations, two are chiefly memorable,—*The Adagia* and *The Greek Testament*. The first edition of the *Adagia* (Paris, 1500) was only the germ of the book afterwards known under that title. This first edition contained 800 proverbs. The last edition in Erasmus's life-time, 1536, has more than 4000. Duplessis (*Bibliogr. parem.*) enumerates 49 editions of the original work, adding that his list is not complete; and he does not mention the numerous abridgments. It is a mere commonplace book, or compilation out of the Greek and Latin classics. The Italian fine writers (Muretus) sneered at it as "rudis indigestaque moles." But it was just what the public wanted, a manual of the wit and wisdom of the ancient world for the use of the modern. The collection was enlivened by commentary in Erasmus's finest vein. Yet so established was the book in the hands of the public that the Council of Trent, unable to suppress it, and not daring to overlook it, ordered the preparation of a castrated edition.

Of Erasmus's Greek Testament the same must be said, viz., that it has no title to be considered as a work of learning or scholarship, yet that its influence upon opinion was profound and durable. It contributed more to the liberation of the human mind from the thraldom of the clergy than all the uproar and rage of Luther's many pamphlets. As an edition of the Greek Testament it has no critical value. But it was the first (*Editio Princeps, Basileæ ap. Jo. Frobenium*, 1516, folio), and it revealed the fact that the Vulgate, the Bible of the Church, was not only a second-hand document, but in places an erroneous document. A shock was thus given to the credit of the clergy in the province of literature, equal to that which was given in the province of science by the astronomical discoveries of the 17th century. Even if Erasmus had had at his disposal the MSS. subsidia for forming a text, he had not the critical skill required to use them. He had at hand two late Basel MSS., which he sent straight to press, correcting them in places by two others. In four subsequent reprints, 1519, 1522, 1527, 1535, Erasmus gradually weeded out the many typographical errors of his first edition, but the text remained essentially such as he had first printed it. The Greek text indeed was but a subordinate part of his scheme. The principal object of the volume was the new Latin version, the original being placed alongside as a guarantee of the translator's good faith. This translation, with the justificatory notes which accompanied it, though not itself a work of critical scholarship, became the starting-point of modern exegetical science. Erasmus did nothing to solve the problem, but to him belongs the honor of having first propounded it.

For an account of the attacks which this publication brought on its author, as well as for a notice of his many literary and other controversies, the reader must be referred to some of the special lives of Erasmus. And no man of letters has had more numerous biographers. Beatus Rhenanus prefixed a brief, but pregnant, memoir to his edition of the *Opera Basileæ*, 1540. The common foundation of all the modern compilations on the life of Erasmus is the sketch which Le Clerc, while he was superintending the Leyden edition of the works, drew up, and published in the *Bibliotheque Choisie*, tome 5. Dr. Jortin adapted and enlarged Le Clerc in his *Life of Erasmus*, 2 vols. 4to, Lond. 1748. "Jortin has made," says Sir W. Hamilton (*Discussions*, p. 218), "as, with his talents, he could hardly fail to make, an amusing farrago out of the life and writings of Erasmus, though not even superficially versed in the literary history of the 16th century. He rarely ventures beyond the text of Erasmus and Le Clerc without stumbling." Other lives are by Samuel Knight, 8vo, Cambr. 1726; Marsollier, 12mo, Paris, 1713; Burigny, 2 vols. 12mo, Paris, 1752; Ad. Müller, 8vo, Hamburg, 1828; Escher, in the *Historisches Taschenbuch*, 1843; Erhard, in Ersch and Gruber's *Encyclopädie*, 1841; D. Nisard, in *Études sur la Renaissance*, 8vo, Paris, 1855; Seebohm, in *Oxford Reformers*, 2d ed. 1869; H. H. Milman, 8vo, Lond. 1870; Stichart, 8vo, Leipsic, 1870; Durand de Laur, 2 vols. 8vo, Par. 1872; R. B. Drummond, 2 vols. 8vo, Lond. 1873; Gaston Feugère, 8vo, Par. 1874; A. R. Pennington, 8vo, Lond. 1875; Kämmel in *Deutsche Biographie*, 1877; besides those which are contained in the various biographical dictionaries from Bayle downwards.

With this abundance of choice, in which the same story is told by a score of writers in English, French, and German, and in every variety of style, we can hardly say, as Sydney Smith did in 1812, that "a life of Erasmus is a desideratum" (*Life of S. Smith*, p. 207). The brochures on separate works of Erasmus, or single stages of his life, are too many to be here enumerated.

His works were published after his death in a collected edition, 9 vols. fol., Basil. 1540. The only other edition is the magnificent one edited by Le Clerc, 10 vols. fol., Lugd. Bat. 1703–6, which includes the *Greek Testament* the *Paraphrasis*, and the *Adagia*, as well as the *Epistolæ*, and smaller writings. It is provided with a good general index in the last volume, and with an excellent special index to the volume containing the epistles. (M. P.)

ERASTUS, Thomas (1524–1583), was born at Baden in Switzerland on the 7th of September, 1524. His family name was Liebler or Lieber, *Erastus* being the Greek equivalent. In 1540 he went to Basel, and in 1542 he entered the university there as student of philosophy and theology. An outbreak of the plague in 1544 drove him to Bologna, where he studied philosophy and medicine, taking his doctor's degree in the latter faculty. His residence in Italy lasted nine years, part of the time being spent at the university of Padua. Returning northwards in 1553, he for some time held the post of physician to the counts of Henneberg. In 1558 he was appointed physician to the Elector Palatine Otto Heinrich, and at the same time he obtained the chair of medicine in the university of Heidelberg. By Frederick III., who succeeded Otto Heinrich in 1559, he was made privy-councillor and member of the church-consistory. Eminent both as a scientific and as a practical physician, he at the same time took a profound interest in the theological controversies of his day, and soon became deeply involved in them. While a student of theology at Basel he had heartily adopted the doctrines of Zwingli, and ever afterwards was prompt to avail himself of all the opportunities which his position afforded for advancing the views of the Zurich divines. At the instance of the elector he took an active part in the sacramentarian conferences held at Heidelberg in 1560 and at Maulbronn in 1564. In connection with these conferences he published a statement and vindication of the Zwinglian doctrine of the Lord's Supper, which, on its being criticised on the Lutheran side by Dr. John Marbach of Strasburg, he followed up with a second defence (1565). Shortly after the settlement of Erastus in Heidelberg, an effort was made to introduce into the church of the Palatinate a strict presbyterian constitution after the Genevan model. Erastus became the leader of an influential opposition to this attempt. He made it his business to counteract what he called the "excommunicatory fever" of the advocates of rigid discipline. In 1568 he wrote and circulated in manuscript 100 theses on the subject of church censures, maintaining that exclusion from participation in the sacraments is not a legitimate punishment for any offence whatsoever (*Explicatio*, ix., xxxi.). A copy of the theses was sent to Zurich, and received with some favor there, but from Geneva they elicited a vigorous rejoinder by Beza, which led to the preparation of a *Confirmatio Thesium*. The efforts of Erastus and his friends at Heidelberg in this matter met with little success, the presbyterian discipline being finally set up in 1570, with hardly any modification of the Genevan strictness. Meanwhile Erastus had lost the favor of the elector, and by a correspondence with some of the Socinians of Transylvania had brought himself under suspicion of being favorable to their views. One of the first acts of the newly constituted church court seems to have been a high-handed excommunication of Erastus, on the ground of his supposed Unitarianism. The sentence was reconsidered and removed in 1575, Erastus formally declaring that no one could hold the doctrine of the Trinity more firmly than he. The court physician, however, found his position at Heidelberg to be one of increasing discomfort. He accordingly returned in 1580 to Basel, where he received an appointment to the chair of ethics in 1583. He died on 31st December of the same year.

Erastus seems to have been much esteemed by his friends for his amiability, candor, and probity. As an investigator of nature, he was honorably distinguished by his adherence to a sound inductive method. Most of the works that appeared during his lifetime were directed against the fantastic notions of Paracelsus and his school (*Dissertationum de Medicina nova Phil. Paracelsi partes quatuor*, Basel, 1572; *De occultis pharmacorum potestatibus*, Basel, 1574; *De auro potabili*, Basel, 1578, and other works). That he was not in advance of his age in regard to witchcraft is shown by his treatise *De lamiis et strigibus* (Basel, 1578), in which he urges upon magistrates the duty of putting witches to death.

The work by which he is best known, though originally written in 1568, and afterwards revised by himself, was first published six years after his death (1589), by Castelvetro, who had married his widow. Its full title is *Explicatio quæstionis gravissimæ utrum excommunicatio, quatenus religionem intelligentes et amplexantes a sacramentorum usu propter admissum facinus arcet, mandato nitatur divino an excogitata sit ab hominibus.* In 75 theses he seeks to show that excommunication is not a divine ordinance but a device of men, and that the sins of professing Christians are to be punished by the civil magistrate with civil penalties, not by pastors and elders denying access to the sacraments. The sacraments, being means of grace, ought not to be withheld from any one wishing to receive them. The punishment of all offences belongs to the civil magistrate exclusively. The church has no power to make laws or decrees, still less to inflict pains and penalties of any kind. Its function is simply to teach, exhort, convince, persuade. In Deut. iv. 8 it is implied that the laws and statutes of the Jewish people were the most perfect possible. That church therefore is most worthily and wisely ordered which comes nearest to the constitution of the Jewish church. But in the Jewish church we find no traces of two diverse judicatories concerning manners, the one civil, the other ecclesiastical. No reason can be alleged why the Christian magistrate at the present day should not possess the same power which God commanded the magistrate to exercise in the Jewish commonwealth.

These views of Erastus were speedily adopted by various eminent divines in England. In the Westminster Assembly there was a distinct Erastian party, of which the most prominent members were Selden, Lightfoot, Coleman, and Whitelocke. After a controversy of many months, in which Selden, Coleman, Gillespie, and Rutherford were the most prominent disputants, the proposition that "the Lord Jesus, as King and Head of His church, hath therein appointed a government, in the hand of church officers, distinct from the civil magistrate," was finally carried, the sole dissentient voice being that of Lightfoot. This proposition, with the whole chapter "Of Church Censures" in which it occurs, was intended and understood to contain a complete rejection of Erastian principles, and in this light it was regarded by the Erastians themselves. That chapter, however (the 30th of the Confession), was never formally ratified by the parliament.

The Anglican doctrine of "the royal supremacy in causes ecclesiastical," it needs hardly be said, is not in any sense derived from Erastus (see the 37th Article; also Hooker's *Eccl. Pol.*, b. viii. and Preface). In Scotland Erastianism is disowned by all Presbyterians. They hold, as against Erastus, that there is "a *government* in the hand of church officers distinct from the civil magistrate." It is well known that serious differences have arisen as to some of the practical effects of this anti-Erastian doctrine. The history of these differences will be related elsewhere. (See SCOTLAND, CHURCH OF, and FREE CHURCH.)

An English translation of the *Explicatio* appeared anonymously in 1659. A new translation, enriched with an interesting preface, was published by the late Dr. Robert Lee (Edin., 1844).

ERATO, the muse who presided over amatory poetry. See MUSES.

ERATOSTHENES, a celebrated astronomer and geometrician of Alexandria, was born at Cyrene, 276 B.C. His fame as an astronomer has cast into the shade his other accomplishments, but in his own day he had some reputation both as a poet and as a grammarian, and he was appointed superintendent of the great Alexandrian library by Ptolemy Euergetes. He died of voluntary starvation, from grief on account of his blindness, 196 B.C. His works, with the exception of the *Catasterismi*, or catalogue of the constellations, exist only in fragments. These have been published by Bernhardy under the title *Eratosthenica* (Berlin, 1822), and the remains of his poetical works have been published separately by Hiller (Leipsic, 1872). For an account of his astronomical and geometrical discoveries see ASTRONOMY, vol. ii. p. 654.

ERBACH, the chief town of a circle in Hesse-Darmstadt, province of Starkenburg, is situated on the Mümling, 22 miles S.E. of Darmstadt. It has cotton and woollen mills, lime and tile works, a tannery, and a manufactory for arms. Wool and cattle fairs are held twice a year. The castle contains interesting collections of Greek, Roman, and German antiquities, and the armor and weapons of many celebrated warriors. In the chapel are the stone coffins of Eginhard son-in-law of Charlemagne and his wife Emma. Erbach has been for a long time the residence of the counts of Erbach, who trace their descent to Eginhard, but the first authentic information regarding them dates from the middle of the 12th century. Since 1532 they have held their title immediately from the empire, and since 1541 have been hereditary cup-bearers. They are now divided into three lines named according to their places of residence, the Erbach-Fürstenau, Erbach-Erbach, and Erbach-Schönberg, who rank, not according to the age of their descent, but according to the age for the time being of the chief of their line. The countship lost its independence in 1806, and is now incorporated with Hesse. The population of Erbach in 1875 was 2663.

ERCILLA Y ZUÑIGA, ALONSO DE (1533–1595), a Spanish soldier and poet, was born in Madrid, August 7, 1533. On the death of his father, Fortunio Garcia de Arcilla y Arteaga, a learned and travelled jurisconsult of Biscayan origin, who held high office under the emperor Charles V., his mother obtained a place in the household of the empress Isabella, and the boy was brought up as a page to Philip, the heir-apparent. In this capacity Ercilla visited the Netherlands, Germany, and Italy, and was present in 1554 at the betrothal of his master to Mary of England. Hearing while he was in London that an expedition was about to start for South America in order to chastise the revolted Araucanians of Chili, he asked and obtained permission to join the adventurers. In the war which ensued he fought bravely and well; but having through an accidental quarrel with a comrade fallen under suspicion of mutiny, he was condemned to death by his general, Garcia de Mendoza, and only escaped, on the discovery of his comparative innocence, with a term of imprisonment. He returned to Spain in 1562, and in the course of the next eight years visited Italy, France, Germany, Bohemia, etc. At Madrid in 1570 he married Maria de Bazan, connected with the Santa Cruz family; in 1570 he was made knight of the order of Santiago; in 1576 he was appointed chamberlain to the emperor Rudolph II.; and in 1578 he was employed by Philip II. on a mission to Saragossa. After several years of poverty and neglect, he died at Madrid about 1595. His principal and, indeed, his almost solitary work is *La Araucaña*, a poem based on the events of the wars in which he had been engaged. It consists of three parts, of which the first, composed between 1555 and 1563, and published in 1569, is a versified narrative adhering strictly to fact and date; the second, published in 1578, is relieved or encumbered by visions and other romantic machinery; and the third, which appeared in 1590, contains, in addition to the subject proper, a variety of episodes relevant and irrelevant. Of symmetry or proportion this so-called epic is almost destitute; but it is written in excellent Spanish, and is full of passages of vigorous and natural description. Cervantes placed it on a level with some of the best Italian poems of its class; Voltaire spoke in warm terms of certain portions; and it is now acknowledged to occupy an honorable position in Spanish literature. It has been frequently reprinted,—at Madrid in 1776 and 1828, and again in 1851, as part of Rivadeneyra's *Biblioteca.* An analysis of the poem was given by Hayley in his *Essay on Epic Poetry*, 1782; and another appeared in *Charaktere der Vornehmsten Dichter aller Nationen*, Leipsic, 1793. A French abridgment was published by Gilbert de Marlhiac in 1824; a German translation by Winterling at Nuremberg, 1831; and a complete French translation at Paris by Al. Nicolas, 1870.

ERDÉLYI, JÁNOS (1814–1868), an Hungarian poet and author, was born in 1814 at Kapos, in the county of Ungvár, and educated at the Protestant college of Sárospatak. In 1833 he removed to Pesth, where, having attracted notice by his poetical talents, he was, in 1839, elected member of the Hungarian Academy of Sciences. His literary fame was much enhanced by his collection of Hungarian national poems and folk-tales, *Magyar Népköltési Gyüjtemény, Népdalok és Mondák* (Pesth, 1846–47). This work, published by the Kisfaludy Society, was supplemented by a dissertation upon Hungarian national poetry, afterwards partially translated into German by Stier (Berlin, 1851). Erdélyi also compiled for the Kisfaludy Society an extensive collection of Hungarian proverbs—*Magyar Közmondások könyve* (Pesth, 1851), and was for some time editor of the *Szépirodalmi Szemle* (*Review of Polite Literature*). In 1848 he was appointed director of the national theatre at Pesth; but after 1849 he resided at his native town. He died on the 23d January, 1868. The most important recent work bearing his name is a collection of folk-lore, published the year after his death, entitled *A Nép Költészete: népdalok, népmesék és közmondások* (Pesth, 1869). This work contains 300 national songs, 19 folk-tales, and 7362 Hungarian proverbs.

ERDMANN, OTTO LINNÉ (1804–1869), a German chemist, was the son of Karl Gottfried Erdmann, the physician who introduced vaccination into Saxony. He was born at Dresden, April 11, 1804. In 1820 and the following year he attended the lectures of the medico-chirurgical academy at Dresden, and in 1822 he entered the university of Leipsic, where he remained three years, devoting himself principally to the study of chemistry. In 1824 he received the degree of doctor of philosophy, and in 1825 that of licentiate of chemistry. In 1827 he became extraordinary professor, and in 1830 ordinary professor, of chemistry at Leipsic, the duties of which office he continued to discharge till his death at Leipsic, 9th October, 1869. At Leipsic Erdmann established a chemical laboratory, which became the model of many similar institutions in Europe. He is best known for his discoveries regarding the qualities of nickel, and of indigo and other dye stuffs. In 1828, in conjunction with Werther, he founded the *Journal für technische und ökonomische Chemie*, and later the *Journal für prachtische Chemie.* He is also the author of *Ueber das Nickel* (1827); *Lehrbuch der Chemie* (1828); *Grundriss der Waarenkunde* (1833); and *Ueber das studium der Chemie* (1861).

EREBUS. This word, which denotes darkness, comes probably from the same source as the Greek ἐρέφω, to cover, and ὀροφή, a roof, and has by some been connected also with the Hebrew Ereb, night, which reappears in Algarve. In the Hesiodic *Theogony*, 123, Erebus is, with Nyx, the night, the offspring of Chaos; and Erebus and Nyx become the parents of Æther and Hemera, the pure air and the day. In the *Odyssey* Erebus becomes the abode of all the dead, without reference to the character of their past lives; and from the *Iliad* it would follow that this abode was within the earth. It is a dreary and cheerless land, the inhabitants of which have no strength either of mind or of body; and thus the idea of Erebus is distinguished from the notion which assigned the righteous dead to Elysium and the wicked to Tartarus. Achilles, who in Elysium inherits a tearless life, declares in Erebus that he would rather toil as a peasant on the earth than be a king in that gloomy abode of departed shades (*Odys.* xi. 489).

ERECHTHEUS, in Greek legend, apparently the same as Erichthonius, was a local hero of Attica, with whom was associated the belief of the Athenians in their ancestors having sprung from the soil (see AUTOCHTHONES). But the story of his birth is told generally under the name of Erichthonius, who, in the form of a serpent, was the offspring of Athena and Hephæstus, and was by the former handed over in a closed basket to the three daughters of Cecrops, Aglaurus, Herse, and Pandrosus, with a command not to open it. When two of them, Aglaurus and Herse, opened it, they became frantic and threw themselves from the Acropolis of Athens. The scene of the opening of the basket is represented on a Greek vase in the British museum, from which it is seen that the figure within it is not altogether of the form of a serpent (= Erichthonius), but has the head and body of a boy, such as were ascribed to Erechtheus. Radically the names of both are connected with the earth (χθών). But while Erechtheus came to be looked upon as a first ancestor, and associated with the introduction of agriculture and other public benefits, his double, so to speak, Erichthonius, retained as a rule the character of a dæmon or semi-divine being.

20. Regler Church.
21. Military School.
22. Prediger Church.

ERFURT, a city of Prussian Saxony, and the capital of an administrative district, is situated on the Gera, and on the line of the Thuringian railway, about midway between Gotha and Weimar, which are 14 miles distant. It is irregularly built, having no street or square worthy of mention, with the exception of the Friedrich-Wilhelmsplatz, which contains a monument to the elector Frederick Charles Joseph of Mayence. Here are also situated the cathedral and the church of St. Severus. The cathedral, built between 1319 and 1351, is one of the finest ecclesiastical buildings in Germany. It contains some very rich portal sculptures and bronze castings, among others the coronation of Maria by Peter Vischer. In one of its towers is the famous bell called St. Maria Gloriosa, which bears the date 1447, and weighs 270 cwt. The name by which this bell is usually known is Grosse Susanna, but this name properly belongs to its predecessor, which was melted by a fire which had attacked the tower. Among the other churches besides that of St. Severus may be mentioned the Prediger, the Regler, and the Barfüsser. The only monastery now used is the Ursuline, which for some time has contained an educational establishment. The Augustine monastery, in which Luther lived as a monk, is now used as an orphanage, under the name of the *Martinsstift.* The cell of Luther was destroyed by fire in 1872. At one time Erfurt had a university, whose charter dated from 1392; but it was suppressed in 1816, and its funds devoted to other purposes, among these being the endowment of an institution founded in 1758, and now called the Royal Academy of Practical Sciences, and the support of the library, which now contains 60,000 vols. and over 1000 manuscripts. Erfurt possesses a great number of educational establishments,—a gymnasium, a normal seminary, a military school, a school of art and architecture, a midwifery school, and a commercial school. It also possesses, besides the *Martinsstift,* two orphanages, a hospital, two infirmaries, and an eye hospital. The most notable industry of Erfurt is the culture of flowers and of vegetables, which is very extensively carried on. This industry had its origin in the large gardens attached to the monasteries. It has also woollen, cotton, linen, and thread mills; stocking, lace, tobacco, leather, and chemical manufactories; breweries and distilleries. Erfurt was formerly the capital of Thuringia, and until 1873 was a fortified town. It is said to have been founded about the 5th century. It was made the seat of a bishop in 740, but soon afterwards lost the dignity. In 805 Charles the Great created it a market town, after which it rose rapidly in importance. Although never strictly a free town, it for a long time retained almost complete political independence. In 1483 it renewed a protection league with Saxony, pledging itself at the same time to a yearly contribution of 1500 guilders. It attained the height of its prosperity about the end of the 15th century, and is said to have then numbered about 60,000 inhabitants. About the middle of the 17th century it was annexed by force to the electorate of Mayence, under which government it remained till 1802, when it came into the possession of Prussia. In 1808 it was the scene of the memorable interview between Napoleon and the emperor Alexander of Russia. Here also in the spring of 1850 the Diet known as the Union's Parliament held its sittings. The population of Erfurt in 1875 was 48,025.

See Humbert, *Les villes de Thuringe*, 1870, and A. W. Fils, *Höhenmessungen von dem Kreise Erfurt, etc.* (Ilmenau, 1865), an extract from which is given in Petermann's *Mittheilungen*, 1865.

ERGOT, or **Spurred Rye**, the drug *ergota* or *Secale cornutum* (Germ. *Mutterkorn;* Fr. *Seigle ergoté*), consists of the sclerotium of a fungus, *Claviceps purpurea*, Tulasne, of the order *Pyrenomycetes*, parasitic on the pistils of many species of the *Graminaceæ*, but obtained almost exclusively from rye, *Secale cereale*, L. In the ear of rye that is infected with ergot a species of fermentation takes place, and there exudes from it a sweet yellowish mucus, which after a time disappears. The ear loses its starch, and ceases to grow, and its ovaries become penetrated with the white spongy tissue of the mycelium of the fungus, termed originally by Léveillé *Sphacelia segetum.* From the mycelium, at the expense of the substance of the ear, is developed the sclerotium or ergot, the *Sclerotium clavus* of De Candolle, and *Spermœdia clavus* of Fries. This, when placed on damp earth, produces the third form of the fungus, its outer cell layers becoming soft, and filiform spore-bearing stalks about an inch in length being thrown out. From the spores, as also from the conidia of the mycelium stage, the mycelium may be again produced.

The drug consists of grains, usually curved (hence the name, from the Old French *argot*, a cock's spur), which are violet-black or dark purple externally, and whitish with a tinge of pink within, are between $\frac{1}{3}$ and $1\frac{1}{2}$ in. long, and from 1 to 4 lines broad, and have two lateral furrows, a close fracture, a disagreeable rancid taste, and a faint, fishy odor, which last becomes more perceptible when the powder of the drug is mixed with potash solution. Ergot should be kept in stoppered bottles in order to preserve it from the attacks of a species of mite, and to prevent the oxidation of its fatty oil.

The oil of ergot, which constitutes 30 per cent. of its weight, appears to consist mainly of palmitic acid, with some oleic acid. Among other constituents the drug, according to Wenzell, contains two bitter alkaloids, *ergotin* and *ecbolin*, and to the latter the special medicinal virtues of the drug are due. From the investigations, however, of Prof. Dragendorff and Herr Padwissotzky, it appears that Wenzell's ergotin and ecbolin are not improbably identical with each other. By those chemists the presence in ergot of the following compounds has been determined:—*scleromucin*, a slimy, colloidal body, soluble in water, insoluble in alcohol; 2 to 3 per cent. of a tasteless and inodorous principle, *sclerotic acid*, also colloidal, soluble in water and in 45 per cent. alcohol, and having, exclusive of a small quantity of ash, the percentage composition—carbon 40, hydrogen, 5·2, nitrogen 4·2, oxygen 50·6; minute quantities of slightly active coloring matters, *sclererythrin* and *scleroiodin*, with *sclerokrystallin*, *scleroxanthin*, and other substances. The subcutaneous injection of from 0·02 to 0·04 gram. of sclerotic acid causes in the frog a state of palsy, accompanied by a peculiar swelling, which lasts six or seven days. (See *Pharm. Journ. and Trans.*, June 17, 1876, p. 1001.) Trimethylamine, C_3H_9N, is said to be obtained from ergot by distillation with potash, but neither that body nor ammonia pre-exists as such in the drug.

The extract, tincture, infusion, and powder of ergot are all employed in medicine. What is commonly termed "ergotin" is an extract first prepared by Bonjean, of Chambéry, whose name it often bears. By age the active medicinal properties of ergot are gradually impaired, and lost. The addition of 1 per cent. of acetic acid is said to render the liquid preparations permanent. The poisonous action of ergot on various animals has been shown by Bonjean, Diez, Gross, Parola, Wright, and others. Thus Tessier found that in pigs it caused first redness of the eyes and ears, then coldness of the limbs and swelling of the joints, and finally gangrene of the extremities and intestines, and death during convulsions. Among the symptoms of poisoning by ergot in man are nausea, salivation, dilatation of the pupils, and subsequent injection of the conjunctiva, some colic, occasionally diarrhœa, coldness of the skin, vertigo, and convulsions. The name *ergotism* has been applied to the disease produced by the eating of food prepared from ergotized rye. It appears to have been the cause of many of the epidemics which in former times occurred in Europe, the last of these being thought to have been that which, at the close of the rainy season of 1816, visited Lorraine and Burgundy. The disease is usually fatal, and manifests itself in two phases, the spasmodic or convulsive and the gangrenous. In the former the first experiences are irritation of the skin, coldness of the body, cramps and numbness of the limbs, and pains in the head and back, followed in from one to three weeks by gastralgia, giddiness, fainting, convulsive movements of the muscles, and other symptoms; frequently the skin becomes spotted with a vesicular eruption. Great exhaustion and craving for food ensue. Examination of the body after death reveals considerable inflammation of the abdominal viscera. Gangrenous ergotism begins with weariness and pain of the limbs; the skin grows dull in hue, and at length dry gangrene attacks the extremities, and when death does not supervene the parts affected are generally lost. Dr. E. R. Squibb (*Year Book of Pharmacy*, 1874, p. 43) considers it probable that the poisoning described as the result of eating ergotized food could occur only among underfed semi-scorbutic people, or under conditions not present in cases ordinarily requiring treatment with ergot. For the detection of the presence of ergot in rye flour a small quantity of the sample is mixed with ether, and a few crystals of oxalic acid are added; if the liquid after being boiled and allowed to grow clear exhibits a red tinge, ergot is present in the sample (Böttger, *Chem. Centralblatt*, 3d ser., ii. 624). Arnal, Beatty, Gibbon, and other experimenters have demonstrated that ergot diminishes the frequency of the pulse. Its power of causing the contraction of the unstriped muscular tissue of the body appears to be due principally to its action on the sympathetic system of nerves. It has been maintained by Brown-Séquard that it occasions first vaso-motor spasm, and secondly vaso-motor paralysis. The powerful and persistent contraction of the uterus to which it gives rise renders it valuable as a prophylactic against hæmorrhage, and also, according to some authorities, as a means of lessening the after-pains. Before the completion of labor its use is contra-indicated when there are obstacles to quick delivery; moreover, the drug may cause the rupture of the uterus, or paralysis of the fœtal heart by pressure, so that it should be excluded from the available means of inducing labor, and ought not to be administered even so late as two hours before the birth. From some cases that have been recorded, it would appear that, even in large doses, the drug may have no effect as an ecbolic if given in the early stages of gestation. Its influence on animals during parturition is the same as that observed in the human female. Ergot has been used generally as a styptic, and has been recommended in amenorrhœa depending on torpidity of the uterus, in chronic dysentery, paraplegia, paralysis of the bladder, paralysis produced by chronic myelitis, epilepsy, whooping-cough, headache, and in obstinate intermittent fevers which are no longer benefited by quinine and arsenic. The hypodermic injection of extract of ergot was first employed for aneurisms by Prof. Langenbeck of Berlin in 1869; and in 1872 Hildebrandt showed its applicability in cases of fibroid tumors of the uterus; it has further been found a rapid and effectual remedy in hæmoptysis, enteric hæmorrhage in typhoid, and in varix and bronchocele. Unless injected in small quantity it is apt to produce much irritation of the subcutaneous tissue.

The earliest mention of ergot is said to occur in the writings of Sigebert de Gremblour. The oxytoxic virtues of the drug. which are noticed by Lonicer, a writer of the 16th century, seem to have been known in France and Germany from a very remote period. It was not, however, until the year 1807 that, through Dr. Stearns, of Saratoga County, the importance of its properties was brought prominently before the medical profession. The general recognition in Britain of its value as a therapeutic agent dates from about the year 1828.

Bonjean, *Traité de l'Ergot de Seigle*, Paris, 1845; Tulasne, "Mémoire sur l'Ergot des Glumacées," *Ann. Sci. Nat. Botan.*, 3d ser., t. xx., 1853; Stillé, *Therapeutics and Materia Medica*, vol. ii., Philad. 1868; Flückiger and Hanbury, *Pharmacographia*, 1874; Wood, *A Treatise on Therapeutics*, Philad. 1874; Ringer, *Handbook of Therapeutics*, 4th ed., 1874; S. Wilson, "Observations and Experiments on Ergot," *Pharm. Journ. and Trans.*, 1876, p. 525 *et seq.* On the therapeutics of ergot important matter will also be found in the various medical journals. (F. H. B.)

ERIE, a city and port of entry, the capital of Erie co., Pennsylvania, is situated on Lake Erie opposite Presque Island, about 120 miles N. of Pittsburg, 42° 8′ N. lat. and 80° 10′ W. long. Its streets are spacious and are laid out with great regularity. The principal buildings are the court-house, the post office, the custom house, the opera house, the union dépôt, the academy, the marine hospital, the city hospital, and the orphan asylum. Erie has railway communication with Buffalo, Philadelphia, and Pittsburg. Its inhabitants are engaged chiefly in various kinds of iron manufacture, and it possesses large rolling mills. It has also leather manufactories, a brass foundry, petroleum refineries, and several large breweries. For many of its manufactories a large supply of water is required, and this is supplied from Lake Erie by powerful engines which force it to the top of a tower 200 feet high, whence it is distributed through the mains. The harbor, which is formed out of the natural bay protected by a breakwater, is 3½ miles long, more than a mile wide, and from 9 to 25 feet deep. The principal shipments are coal, iron, and petroleum; and the total value of imports from Canada for the year ending 31st March, 1877, was $297,392, and of exports $64,921. For the same period, the number of vessels in the coastwise trade was—entered, 279 steamers with 255,106 tonnage, and 348 sailing vessels with 152,830 tonnage; cleared, 268 steamers with 250,054 tonnage, and 365 sailing vessels with 152,916 tonnage. It was at Erie that Commander Perry equipped the vessels which in 1813 defeated the British fleet on Lake Erie. Erie was laid out in 1795, was incorporated as a borough in 1805, and received a city charter in 1851. The population in 1870 was 19,646.

ERIE, LAKE. See ST. LAWRENCE.

ERIGENA, JOHANNES SCOTUS, one of the most important thinkers of the Middle Ages, flourished during the 9th century. The date and place of his birth are still undetermined. He was undoubtedly a native of the British isles, but of which is quite uncertain. He has been claimed for England by Gale, who thinks that the name *Erigena* is derived from Ergene in Herefordshire; for Scotland by Mackenzie, who supposes him to have been born at Aire; for Ireland by Moore and the majority of writers. The name Erigena, often written *Jerugena*, seems to point to Ireland, *Ierne*, as the place of his birth or training; *Scotus* may be thought to indicate that he was of Scottish extraction. As to the date of his birth, the best authorities fix it about 800–810, but on grounds entirely conjectural. Of his early education little or nothing is known. He appears to have studied in the best schools of Ireland, and to have been destined for the church. It is highly improbable, however, that he took orders as a priest. Had he done so, some reference would be made to the fact by those who attacked his writings as unorthodox. From his knowledge of Greek, and from a passage in a certain MS. ascribed to him, it has been supposed that he had travelled and studied in Greece. But the passage is of doubtful authority, and the knowledge of Greek displayed in his works is not such as to compel us to conclude that he had actually visited Greece. That he had a competent acquaintance with the Greek language is manifest from his translations of Dionysius the Areopagite and of Maximus, from the manner in which he refers to Aristotle, and from his evident familiarity with neo-Platonist writers and the fathers of the early church. Roger Bacon, in his severe criticism on the ignorance of Greek displayed by the most eminent scholastic writers, expressly exempts Erigena, and ascribes to him a knowledge of Aristotle in the original.

The only portion of Erigena's life as to which we possess accurate information was that spent at the court of Charles the Bald. Charles invited the philosopher to France soon after his accession to the throne, probably in the year 843, and placed him at the head of the court school,—*schola palatina*. The reputation of this school or college seems to have increased greatly under Erigena's leadership, and the philosopher himself was treated with the greatest familiarity and indulgence by the king. William of Malmesbury's amusing story illustrates both the character of Scotus and the position he occupied at the French court.

The first of the works known to have been written by Scotus during this period was a treatise on the eucharist, which has not come down to us. In it he seems to have advanced the doctrine that the eucharist was merely symbolical or commemorative, an opinion for which Berengarius was at a later day censured and condemned. As a part of his penance Berengarius is said to have been compelled to burn publicly Erigena's treatise. So far as we can learn, however, Erigena's orthodoxy was not at the time suspected, and a few years later he was selected by the famous Hincmar to defend the doctrine of liberty of will against the extreme predestinarianism of the monk Gottshalk (Godeschalchus). The treatise *De Divina Predestinatione*, composed on this occasion, has been preserved, and from its general tenor and method one cannot be surprised that the author's orthodoxy was at once and vehemently suspected. Scotus argues the question entirely on speculative grounds, and starts with the bold affirmation that philosophy and religion are fundamentally one and the same—"Conficitur inde veram esse philosophiam veram religionem, conversimque veram religionem esse veram philosophiam" (*De Div. Pred.*, i. 1). Even more significant is his handling of authority and reason, to which we shall presently refer. The work was warmly assailed by Florus and Prudentius, and was condemned by two councils—that of Valence in 855, and that of Langres in 859.

Erigena's next work was a translation of Dionysius the Areopagite (see DIONYSIUS), undertaken at the request of the king. This also has been preserved, and fragments of a commentary by Scotus on Dionysius have been discovered in MS. A translation of the Areopagite's pantheistical writings was not likely to alter the opinion already formed as to Erigena's orthodoxy. Pope Nicholas I. was offended that the work had not been submitted for approval before being given to the world, and ordered Charles to send Scotus to Rome, or at least to dismiss him from his court. There is no evidence, however, that this order was attended to. Erigena appears still to have remained in favor.

The latter part of his life is involved in total obscurity. The story that in 882 he was invited to Oxford by Alfred the Great, that he labored there for many years, became abbot at Malmesbury, and was murdered by his scholars, is apparently without any satisfactory foundation, and doubtless refers to some other Johannes. Erigena in all probability never left France, and Hauréau has advanced some reasons for fixing the date of his death about 877.

The works of Erigena that have come down to us are the following:—(1) the treatise on predestination, first published in 1650; (2) a commentary on Marcianus Capella, published by Hauréau in 1861; (3) translation of Dionysius the Areopagite, published in Floss's edition of Erigena, vol. cxxii. of Migne's *Patrologiæ Cursus Completus;* (4) miscellaneous treatises, some still in MS., *e.g.*, the work *De Visione Dei*, and the commentary on Dionysius, which has been published in *Appendix ad Opera edita ab Ang. Maio*, Rom., 1871; (5) translation of St. Maximus's scholia on Gregory of Nazianzen, published in Gale's edition of (6) the great work, *De Divisione Naturæ, περὶ φυσέων μερίσμου.* Of this last work three editions have appeared—that of Gale, Oxford, 1681, that by Schlüter, 1838, and that by Floss, 1853.

Erigena is without doubt the most interesting figure among the Middle Age writers. The freedom of his speculation, and the boldness with which he works out his logical or dialectical system of the universe, altogether prevent us from classing him along with the scholastics properly so called. He marks, indeed, a stage of transition from the older Platonizing philosophy to the later and more rigid scholasticism. In no sense whatever can it be affirmed that with Erigena philosophy is in the service of theology. The above-quoted assertion as to the substantial identity between philosophy and religion is indeed repeated almost *totidem verbis* by many of the later scholastic writers, but its significance altogether depends upon the selection of one or other term of the identity as fundamental or primary. Now there is no possibility of mistaking Erigena's position: to him philosophy or reason is first, is primitive; authority or religion is secondary, derived. "Auctoritas siquidem ex vera ratione processit, ratio vero nequaquam ex auctoritate. Omnis enim auctoritas, quæ vera ratione non approbatur, infirma videtur esse. Vera autem ratio, quum virtutibus suis rata atque immutabilis munitur, nullius auctoritatis adstipulatione roborari indiget" (*De. Div. Nat.*, i. 71). F. D. Maurice, the only historian of note who declines to ascribe a rationalizing tendency to Erigena, obscures the question by the manner in which he states it. He asks his readers, after weighing the evidence advanced, to determine "whether he (Erigena) used his philosophy to explain away his theology, or to bring out what he conceived to be the fullest meaning of it." These alternatives seem to be wrongly put. "Explaining away theology" is something wholly foreign to the philosophy of that age; and even if we accept the alternative, that Erigena endeavors speculatively to bring out the full meaning of theology, we are by no means driven to the conclusion that he was primarily or principally a theologian. He does not start with the datum of theology as the completed body of truth, requiring only elucidation and interpretation; his fundamental thought is that of the universe, nature, *τό πᾶν*, or God, as the ultimate unity which works itself out into the rational system of the world. Man and all that concerns man are but parts of this system, and are to be explained by reference to it; for explanation or understanding of a thing is determination of its place in the universal or all. Religion or revelation is one element or factor in the divine process, a stage or phase of the ultimate rational life. The highest faculty of man, reason, *intellectus, intellectualis visio*, is that which is not content with the individual or partial, but grasps the whole and thereby comprehends the parts. In this highest effort of reason, which is indeed God thinking in man, thought and being are at one, the opposition of being and thought is overcome. When Erigena starts with such propositions, it is clearly impossible to understand his position and work if we insist on regarding him as a scholastic, accepting the dogmas of the church as ultimate data, and endeavoring only to present them in due order and defend them by argument.

Erigena's great work, *De Divisione Naturæ*, is arranged in five books. The form of exposition is that of dialogue; the method of reasoning is the syllogistic. The leading thoughts are the following. *Natura, φύσις*, is the name for the universal, the totality of all things, containing in itself being and non-being. It is the unity of which all special phenomena are manifestations. But of this nature there are four distinct classes:—(1) that which creates and is not created; (2) that which is created and creates; (3) that which is created and does not create; (4) that which neither is created nor creates. The first is God as the ground or origin of all things, the last is God as the final end or goal of all things, that into which the world of created things ultimately returns. The second and third together compose the created universe, which is the manifestation of God, God *in processu, Theophania*. Thus we distinguish in the divine system beginning, middle, and end; but these three are in essence one—the difference is only the consequence of one finite comprehension. We are compelled to envisage this eternal process under the form of time, to apply temporal distinctions to that which is extra- or supra-temporal. The universe of created things, as we have seen, is twofold:—*first*, that which is created and creates,—the primordial ideas, archetypes, immutable relations, divine acts of will, according to which individual things are formed; *second*, that which is created and does not create,—the world of individuals, the effects of the primordial causes, without which the causes have no true being. Created things have no individual or self-independent existence; they are only in God; and each thing is a manifestation of the divine, *theophania, divina apparitio*.

God alone, the uncreated creator of all, has true being. He is the true universal, all-containing and incomprehensible. The lower cannot comprehend the higher, and therefore we must say that the existence of God is above being, above essence; God is above goodness, above wisdom, above truth. No finite predicates can be applied to him; his mode of being cannot be determined by any category. True theology is negative. Nevertheless the world, as the *theophania*, the revelation of God, enables us so far to understand the divine essence. We recognize his being in the being of all things, his wisdom in their orderly arrangement, his life in their constant motion. Thus God is for us a Trinity—the Father as substance or being (*οὐσία*), the Son as wisdom (*δύναμις*), the Spirit as life (*ἐνέργεια*). These three are realized in the universe—the Father as the system of things, the Son as the word, *i.e.*, the realm of ideas, the Spirit as the life or moving force which introduces individuality and which ultimately draws back all things into the divine unity. In man, as the noblest of created things, the Trinity is seen most perfectly reflected: *intellectus* (*νοῦς*), *ratio* (*λόγος*), and *sensus* (*διάνοια*) make up the threefold thread of his being. Not in man alone, however, but in all things, God is to be regarded as realizing himself, as becoming incarnate.

The infinite essence of God, which may indeed be described as *nihilum*, nothing, is that from which all is created, from which all proceeds or emanates. The first procession or emanation, as above indicated, is the realm of ideas in the Platonic sense, the word or wisdom of God. These ideas compose a whole or inseparable unity, but we are able in a dim way to think of them as a system logically arranged. Thus the highest idea is that of *goodness;* things *are*, only if they are good; being without well-being is naught. *Essence* participates in goodness—that which is good has being, and is therefore to be regarded as a species of good. *Life*, again, is a species of essence, *wisdom* a species of life, and so on, always descending from genus to species in a rigorous logical fashion.

The ideas are the eternal causes, which, under the moving influence of the spirit, manifest themselves in their effects, the individual created things. Manifestation, however, is part of the being or essence of the causes; that is to say, if we interpret the expression, God of necessity manifests himself in the world and is not without the world. Further, as the causes are eternal, timeless, so creation is eternal, timeless. The Mosaic account, then, is to be looked upon merely as a mode in which is faintly shadowed forth what is above finite comprehension. It is altogether allegorical, and requires to be interpreted. Paradise and the Fall have no local or temporal being. Man was originally sinless and without distinction of sex. Only after the introduction of sin did man lose his spiritual body and acquire the animal nature with its distinction of sex. Woman is the impersonation of man's sensuous and fallen nature; on the final return to the divine unity, distinction of sex will vanish, and the spiritual body will be regained.

The most remarkable and at the same time the most obscure portion of the work is that in which the final return to God is handled. Naturally sin is a necessary preliminary to this redemption, and Scotus has the greatest difficulty in accounting for the fact of sin. If God is true being, then sin can have no substantive existence; it cannot be said that God knows of sin, for to God knowing and being are one. In the universe of things, *as* a universe, there can be no sin; there must be perfect harmony. Sin, in fact, results from the will of the individual, who falsely represents something as good which is not so. This misdirected will is punished by finding that the objects after which it thirsts are in truth vanity and emptiness. Hell is not to be regarded as having local existence; it is the inner state of the sinful will. As the object of punishment is not the will or the individual himself, but the misdirection of the will, so the result of punishment is the final purification and redemption of all; even the devils shall be saved. All, however, are not saved at once; the stages of the return to the final unity, corresponding to the stages in the creative process, are numerous and are passed through slowly. The ultimate goal is *deificatio, theosis*, or resumption into the divine being when the individual soul is raised to a full knowledge of God, and where knowing and being are one. After all have been restored to the divine unity, there is no further creation. The ultimate unity is that which neither is created nor creates.

Editions of the *De Divisione Naturæ* have been enumerated above. The work has been very ably translated into German by Noak, *J. S. E. über die Eintheilung der Natur, ubersetzt und mit einer Schlussabhandlung*, 3 vols., 1874–76. Monographs on his life and works are numerous; the best are St. René Taillandier, *Scot. Erigène et la Phil. Scot.*, 1843; Christlieb, *Leben u. Lehre d. J. S. E.*, 1860; Huber, *J. S. E.*, 1861; Kaulich, *Speculative System des J. S. E.*, 1860; Stöckl, *De Joh. Scoto Erigena*, 1867. See also the general works on scholastic philosophy, especially Hauréau, Stöckl, and Kaulich. For English readers a most admirable résumé is given by Maurice, *Mediæval Phil.*, pp. 45–79. (R. AD.)

ERIGONE. In the Attic myth of Dionysus, Erigone is the daughter of Icarius, who, having received from Dionysus the gift of wine, shares it with some shepherds, who, drinking it undiluted, fancy themselves poisoned, and having murdered Icarius, throw his body into a well. Guided by her dog Maira (the glistening one), Erigone—whose name, like that of Protogeneia (see ENDYMION), denotes one born in early morning—discovers the crime, and hangs herself. After her death she is said to have been translated to the constellation which the Latins called Virgo.

ERINNA, a Greek poetess, the contemporary and friend of Sappho, was probably a native of Rhodes or the adjacent island of Telos, and was born about 630 B.C. Although she died at the early age of nineteen, her poems were amongst the most famous of her time. Of her best known poem, called Ἠλακάτη (the *Distaff*), which contained 300 lines, only 4 lines are now extant. It was written in a mixed dialect of Dorian and Eolian. Three epigrams in the Palatine anthology are also ascribed to her; but two of these are possibly spurious. Another poetess of this name is said to have flourished in the age of Demosthenes, but her existence is matter of considerable uncertainty. The Erinna fragments were collected in Bergk's *Poetæ Lyrici Græci* (Leipsic, 1867).

ERINYES, the Greek name for the beings whom the Latins called Furiæ, Furies. They were especially the avengers of iniquity, and, as such, acquired a character so fearful that those who had need to speak of them called them the Eumenides, or merciful beings, to win from them the pity which they were but little supposed to feel. The name Erinyes cannot be explained from the Greek language; but in the Hymns of the Rig-Veda constant mention is made of Saranyu, who there is the Dawn whose light steals across the heaven, revealing the things of darkness. Of this being the Vedic hymn-makers speak as finding out the evil deeds done during the night, and punishing the wrong-doer. But although for the Greeks, who had forgotten the meaning of the name, they had put on terrible attributes, the Erinyes still retained in their Western home some of their ancient characteristics. Thus for the toil-worn and suffering Œdipus, who unwittingly finds himself in their sacred grove near Athens, they have only a genial welcome. In the Vedic hymns, again, Saranyu draws the long threads of light across the sky. These threads become in the hands of the Erinyes who bear her name, and in those of the kindred Mœræ, or Fates, the threads of human destiny. The idea thus suggested was drawn out more fully in the myths of the Teutonic Norns, or Weird Sisters, who are three in number, as representing the past, the present, and the future. In the later versions of the Greek myth, the Erinyes were also said to be three, their names, Alecto, Megæra, and Tisiphone, denoting relentless hatred, jealousy, and revenge.

ERIPHYLE, in Greek mythology, the wife of the seer Amphiaraus, whom the Argive chief Adrastus took with him to Thebes, because a prophecy had said that that city could not otherwise be taken. Not wishing to meddle in a quarrel which was not his own, Amphiaraus was compelled, by a promise which he had previously given to Adrastus, to abide by the decision of Eriphyle; and Eriphyle had been bribed by Polynices, the son of Œdipus, with the gift of the necklace of Harmonia, to pronounce in favor of the expedition. Thus constrained to go, the seer charged his sons to slay their mother if they should hear of his death, and to march against Thebes. The enterprise of Adrastus, known as the first Theban war, failed, and the earth opening swallowed Amphiaraus in his chariot. His son Alcmæon upon this slew his mother, whose Erinys gave him no rest until he surrendered to Phœbus the necklace of Harmonia and found out a spot to dwell in on which the sun had never shone at the time of Eriphyle's death. Such a place of banishment he found on the islands called Œniadæ, which had grown up at the mouth of the river Achelous from the deposits brought down by its stream. Here he married Callirhoe, the daughter of the river god, who causes his death at the hands of the sons of Phegeus by insisting on his fetching her the necklace of Eriphýle.

ERIS, in Greek mythology, a sister of the war-god Ares, and in the Hesiodic theogony a daughter of Nyx, the night, who is also the mother of righteous recompense, Nemesis. In the *Iliad* Eris, or Strife, is described as insignificant at first, but as swelling until her head touches the heavens. In the legend of the Trojan war, Eris is the goddess who at the marriage festival of Peleus and Thetis flings on the table a golden apple, which is inscribed as a gift for the fairest of the fair. The rivalry of the three deities—Hera, Aphrodite, and Athena—for the gift is decided by the Judgment of Paris, who, being appointed umpire by Zeus, bestows it on Aphrodite. In the *Æneid* she appears under the name of Discordia.

ERIVAN, or IRWAN, in Persian REWAN, a town of Russian Armenia, at the head of a province of the same name, is situated 3430 feet above the level of the Black Sea, on the Zengui, Zanga, or Hrastan, an affluent of the Araxes, about 171 miles S.S.W. of Tiflis by road. The old Persian portion of the town consists mainly of narrow crooked lanes inclosed by mud walls, which effectually conceal the houses, and the modern Russian portion is laid out in long ill-paved streets. On a steep rock, rising about 600 feet above the river, stands the old Turkish fortress, surrounded by ditches and earthen ramparts, and containing within its area part of the palace of the ancient Persian governors, a handsome but greatly dilapidated mosque, a Greek church of modern erection, a cannon foundry, and barracks. One chamber, called the Hall of the Sardar, bears witness to the former splendor of the palace by its pictorial decorations, which include legendary and historical scenes from the lives of Zal and Rustam, of Abbas Mirza and Nadir Shah. The finest building in the city is undoubtedly the mosque of Hussein Ali Khan, familiarly known as the Blue Mosque from the color of the enamelled tiles with which it is richly encased. At the mosque of Zal Khan a yearly passion play is performed illustrative of the assassination of Hussein the son of Ali. Besides the episcopal church of St. Sergius (*Sourp Sarghis*), the Armenians possess five churches, a monastery, and a seminary. Several hundred travellers can be accommodated in the new caravanserai; and there is a club which in some degree makes up for the absence of hotels. The bazaar, though extensive, is poorly supplied with goods; and the only manufactures of the town are a little cotton cloth, leather, earthenware, and blacksmiths' work. The fruits of the district are exceedingly cheap, and noted for their excellence—especially the grapes, apples, apricots, and melons. The surrounding country is richly watered by a system of canals connected with the Gokcha or Sevanga Lake and the river Zengui. Armenians, Persians, and Tatars are the main elements in the population, to which is added a certain number of Russians and Greeks—making a total in 1874 of 30,000.

The origin of Erivan is altogether unknown. One pious Armenian tradition recognizes in the name the joyful exclamation of Noah at the reappearance of the dry ground—*Erevan*, it has shown itself; another explains it as equivalent to *Erovantavan*, the place of defeat of Erovant II. of Armenia; and a third identifies it with the name of Rewan Kul, who built a castle about 1412 on the spot at the command of Shah Ismail. The present fortress at any rate was erected by the Turks in the 16th century, and since that time the place has been of considerable celebrity. It was taken by the Persians under Shah Abbas in 1604, besieged by the Turks for four months in 1615, and reconquered by the Persians under Nadir Shah in the 18th century. In 1780 it was successfully defended against Heraclius of Georgia; and in 1804 it resisted the Russians under Prince Tsitsianoff. At length in 1827 Paskievitch took the fortress by storm, and in the following year the town and province were ceded to Russia by the peace of Turkmanchai. The successful general was rewarded by the title of Count of Erivan (Erivanski). A Tatar poem in celebration of the event has been preserved by Bodenstedt in his "Thousand and One Days in the East."

ERLANGEN, a town of Bavaria, in the district of Middle Franconia, is situated at the confluence of the Schwabach with the Regnitz, eleven miles N.N.W. of Nuremberg, and on the railway between that town and Bamberg. It is surrounded by walls, and divided into an old and new town, the latter consisting of wide, straight, and well-built streets. It possesses a large brewery, the beer of which is in high repute in Germany; and among its other industries are stocking and glove making, glass and tobacco manufacture, and cotton-spinning. It is, however, best known as the seat of a university founded by Frederick, margrave of Bayreuth, who in 1742 established a university at Bayreuth, but in 1743 changed its situation to Erlangen. A statue of this margrave, erected in 1843 by King Louis of Bavaria, stands in the market-place, facing the university buildings. The university occupies the ancient palace of the margraves of Bayreuth, and has faculties of arts, medicine, and theology. At the beginning its endowments were small, but they have latterly become considerable, especially through the benefactions of the margrave Alexander. The number of students in attendance in 1876 was 429. Connected with the university are a library containing 110,000 volumes and 1000 manuscripts, an infirmary, an eye hospital, a maternity hospital, an anatomical museum, and a botanic garden. Erlangen also possesses a gymnasium and a commercial school. The town owes the foundation of its prosperity chiefly to the French Protestant refugees who settled here on the revocation of the Edict of Nantes and introduced various manufactures. In 1017 Erlangen was transferred from the bishopric of Würzburg to that of Bamberg; in 1361 it was transferred to that of Bohemia; it came into the possession of the counts of Nuremberg in 1400, of the margraves of Bayreuth in 1541, of Prussia in 1791, and of Bavaria in 1809. The population in 1875 was 13,597.

ERLAU (the Hungarian *Eger*, Slavonic *Jager*, and Latin *Agria*), a fortified town of Hungary, capital of the vármegye or county of Heves, on the Erlau, or Eger, an affluent of the Theiss (47° 54′ N. lat., 20° 22′ E. long.), 67 miles E.N.E. of Pesth. Previous to 1803, Erlau was the see of a bishopric founded by St. Stephen, king of Hungary in the 11th century; in 1804 it was elevated to an archbishopric. The town is situated in a valley surrounded by hills covered with vineyards, the cultivation of which forms the chief employment of the inhabitants; the red wines from this district are considered the best in Hungary, and are largely exported to foreign countries. The other manufactures consist of woollen and linen fabrics, hat and shoe making, and leather dressing. The town is inclosed by old walls and entered by six gates; the streets are narrow, but embellished with several fine buildings, the principal of which are the cathedral, the archbishop's palace, a diocesan lyceum with a library and observatory 172 feet high, the county hall, and two monasteries. Besides the cathedral, there are several other Roman Catholic churches, also a Greek and a Protestant church, and several schools. Erlau was founded by King Stephen of Hungary, who resided there in 1010. On an eminence above the tower stands an ancient Turkish fortress, which was often besieged during the constant wars between the Moslems and Christians. In 1552 the town resisted the repeated assaults of a large Turkish force; in 1596, however, it was given up to the Turks by the Austrian party in the garrison. During the revolution of 1848–49, Erlau was remarkable for the patriotic spirit displayed by its inhabitants; and it was here that the principal campaigns against the Austrians were organized. The population at the census of 1870 numbered 19,150, chiefly Roman Catholics.

ERLKÖNIG, or Erl-King, a mythical character in modern German literature, represented as a gigantic, bearded man with a golden crown and trailing garments, who carries children away to that undiscovered country where he himself abides. There is no such personage in ancient German mythology, and the name is linguistically nothing more than the perpetuation of a blunder. It first appeared in Herder's *Stimmen der Völker*, 1778, where it is used in the translation of the Danish song of the *Elf-King's Daughter* as equivalent to the Danish *ellerkonge*, or *ellekonge*, that is, *elverkonge*, the king of the elves; and the true German word would have been *Elbkönig*, or *Elbenkönig*, afterwards used under the modified form of *Elfenkönig* by Wieland in his *Oberon*, 1780. Herder was probably misled by the fact that the Danish word *elle* signifies not only elf, but also alder-tree (Germ. *Erle*). His mistake at any rate has been perpetuated by both English and French translators, who speak of a "king of the alders," "*un roi des aunes*," and find an explanation of the myth in the tree-worship of early times, or in the vapory emanations that hang like weird phantoms round the alder-trees at night. The legend was adopted by Goethe as the subject of one of his finest ballads, rendered familiar to English readers by the translations of Lewis and Sir Walter Scott; and since then it has been treated as a musical theme by Reichardt and Schubert. See *Notes and Queries*, 4th series, vol. ix. (1872).

ERMAN, Paul (1764–1851), a German physicist, was born in Berlin February 29, 1764. He originally intended to study for the church, but his inclination towards physical science induced him to change his purpose, and he became teacher of science at the French gymnasium in Berlin, and afterwards at the military academy. On the foundation of the university of Berlin in 1810 he became professor of physics, an office which he held until his death, 11th October, 1851. In 1806 he became a member of the Academy of Physical Science. Erman made various discoveries of some importance in the departments of electricity, magnetism, optics, and physiology. His son, George Adolph, still living (1878), is a well-known physicist and geographer.

ERMINE (*Mustela erminea*), a carnivorous mammal belonging to the family *Mustelidæ*, or Weasels, and resembling the other members of the family in the great length and slenderness of its body and the shortness of its limbs, to which it owes the peculiar snake-like character of its motions. It usually measures 10 inches in length exclusive of the tail, which is about four inches long, and which becomes bushy towards the point. Its fur in summer is of a reddish-brown color above and white beneath, changing in the winter of northern latitudes to snowy whiteness, except at the tip of the tail, which at all seasons is of a jet-black color. In Scottish specimens this change in winter is complete, but in those found in the southern districts of England it is usually only partial, the ermine presenting during winter a piebald appearance. The white color is evidently protective, enabling the animals to elude the observation of their enemies, and to steal unobserved on their prey. It also retains heat better than a dark covering, and may thus serve to maintain an equable temperature at all seasons within the body. According to Bell (*British Quadrupeds*, 2d ed.), the change of color is effected "not by the loss of the summer coat and the substitution of a new one for the winter, but by the actual change of color in the existing fur." The ermine is a native of the northern parts of both hemispheres, inhabiting thickets and stony places, and frequently making use of the deserted burrows of moles and other underground mammals. It is exceedingly sanguinary in disposition, and agile in its movements; it feeds principally on the rat, the water vole, and the rabbit, which it pursues with unusual pertinacity and boldness, hence the name *stoat*, signifying bold, by which it is commonly known. It takes readily to the water, and will even climb trees in pursuit of its prey. It is particularly destructive to poultry and game, and has often been known to attack the hare, fixing itself to the throat of its victim, and defying all the efforts of the latter to disengage it. Although among the fiercest, it is also one of the most playful of creatures, gambolling on the turf, turning somersaults, and performing the most grotesque antics, apparently without other purpose than its own amusement. In approaching its prey even it indulges in the same playful propensity, but it may then be done with the view of allay-

The Ermine.

ing suspicion in its intended victim. The female brings forth five young ones about the beginning of summer. The winter coat of the ermine forms one of the most valuable of commercial furs, and is imported in enormous quantities from Norway, Sweden, Russia, and Siberia. It is largely used for muffs and tippets, and as a trimming for state robes, the jet-black points of the tails being inserted at regular intervals as an ornament. In the reign of Edward III. the wearing of ermine was restricted to members of the royal family. It now enters more or less plentifully into almost all state robes, the rank and position of the wearer being in many cases indicated by the presence or absence, and the disposition, of the black spots. In capturing the animal a trap is used, consisting of a heavy stone slab, supported by a slender stick, baited with flesh; no sooner does the ermine begin to nibble at the bait than the delicate support gives way, and it is crushed beneath the stone.

ERNESTI, Johann August (1707–1781), one of the most illustrious philologists and theologians of the last century. He was born August 4, 1707, at Tennstädt in Thuringia, of which place his father, Johann Christoph Ernesti, likewise a distinguished theologian, was pastor, besides being superintendent of the electoral dioceses of Thuringia, Salz, and Sangerhausen. After having received his first instruction in classics from his father, and in the gymnasium of his native town, he was sent at the age of sixteen to the celebrated Saxon cloister school of Pforta. At twenty he entered the university of Wittenberg, and studied afterwards at the university of Leipsic. In 1730 he was made master in the faculty of philosophy. In the following year he accepted the office of conrector in the Thomas school of Leipsic, of which J. M. Gesner was then rector; and on Gesner's being called in 1734 as professor of rhetoric to Göttingen, he succeeded him as rector. He was, in 1742, named extraordinary professor of ancient literature in the university of Leipsic, and in 1756 promoted to the ordinary professorship of rhetoric. Here his reputation as a scholar, and his rational treatment of biblical exegesis, paved the way for his entrance into the theological faculty, in which he received his doctor's degree in 1758. Through the elegance of his learning, and his manner of discussion, he co-operated with Baumgarten of Halle in disengaging dogmatic theology from the scholastic and mystical excrescences with which it was then deformed, and thus paved the way for a revolution in theology. He died, after a short illness, in his seventy-sixth year, September 11, 1781.

It is perhaps as much from the impulse which Ernesti gave to sacred and profane criticism in Germany, as from the intrinsic excellence of his own works in either department, that he must derive his reputation as a philologist or theologian. In conjunction with Gesner, he instituted a new school in ancient literature, while with Semler he partially co-operated in the revolution of Lutheran theology.

From the Reformation down to the latter half of the 18th century, Germany was far excelled by Holland in the number and excellence of her philologists; and it was not until the appearance of Gesner and Ernesti, with their somewhat earlier contemporaries, Cortius, Daniel Longolius, and Michael Heusinger, that she could oppose above one or two rivals to the great critics of the Dutch schools. Gesner and Ernesti, however, through the influence of their lectures at the greater universities of Göttingen and Leipsic, through the wider extent of their labors in philology, and still more through the greater excellence of their methods, are entitled to be held the founders of the new German school of ancient literature. Both, but especially Ernesti, detected grammatical niceties in the Latin tongue, in regard to the consecution of tenses, for instance, which had escaped preceding critics. His canons are, however, not without exceptions. As an editor of the Greek classics, Ernesti deserves hardly to be named beside his Dutch contemporaries, Hemsterhuis, Valckenaer, Ruhnken, or his colleague Reiski. The higher criticism was not even attempted by Ernesti. But to him and to Gesner the praise is due of having formed, partly by their discipline and partly by their example, philologists greater than themselves, and of having kindled the national enthusiasm for ancient learning.

As a theologian, Ernesti is far less conspicuous than as a scholar, and his influence is not so marked either on his contemporaries or on his successors. It is, indeed, chiefly in hermeneutics that Ernesti has any claim to the character of a great theologian. But here his merits are distinguished, and, at the period when his *Institutio Interpretis N. T.* was published, almost peculiar to himself. In it we find the principles of a general interpretation, formed without the assistance of any particular philosophy, but consisting of observations and rules which, though already enunciated, and applied in the criticism of the profane writers, had never rigorously been employed in biblical exegesis. He admits in the sacred writings as in the classics only one acceptation, and that the grammatical, convertible into and the same with the logical and historical. He therefore justly censures the opinion of those who in the illustration of the Scriptures refer everything to the illumination of the Holy Spirit, as well as that of others who, disregarding all knowledge of the languages, would explain words by things, and thus introduce into the holy writings their peculiar glosses and opinions. The "analogy of faith," as a rule of interpretation, he greatly limits, and teaches that it can never alone afford the explanation of words, but only determine the choice among their possible significations, and must always stand in need of philology as an assistant. Every principle of his interpretation, however, rests on the assumption of the inspiration of the Scriptures, and he seems unconscious of any inconsistency between that doctrine as usually received and his principles of hermeneutics. It must be admitted that those of his followers who have seen the inconsistency, and endeavored by one means or other to obviate it, have been more logical than their master. In the higher criticism of the sacred books Ernesti did nothing. In dogmatic he always expressed great contempt of strict systematic theology; and though he lectured for many years on the *Aphorisms* of Neumann, it was rather in refutation than in support of his text-book.

Among his works the following are the more important—I. In classical literature: *Initia Doctrinæ Solidioris*, 1736, 8vo, many subsequent editions; *Initia Rhetorica*, 1730; editions mostly annotated, of Xenophon's *Memorabilia* (1737), Cicero (1737–39), Suetonius (1748), Tacitus (1752), the *Clouds* of Aristophanes (1754), Homer (1759–64), Callimachus (1761), Polybius (1764), as well as of the *Quæstura* of Corradus, the Greek lexicon of Hedericus, and the *Bibliotheca Latina* of Fabricius (unfinished); *Archæologia Litteraria*, 1768, a new and improved edition by Martini; *Horatius Tursellinus de Particulis*, 1769. II. In sacred literature: *Antimuratorius, sive Confutatio Disputationis Muratorinæ de rebus liturgicis*, 1755–58; *Neue Theologische Bibliothek*, vols. i. to x., 1760–69, 8vo; *Institutio Interpretis Nov. Test.*, 3d ed., 1775, 8vo; *Neueste Theologische Bibliothek*, vols. i. to x., 1771–75, 8vo. Besides these, he published above a hundred smaller works in the form of prefaces, academical dissertations, programmata, memoriæ, elogia, epistles, orations, translations, etc., many of which have been collected in the three following publications:—*Opuscula Oratoria*, 1762, 2d edit., 1767, 8vo; *Opuscula Philologica et Critica*, 1764, 2d edit., 1776, 8vo; *Opuscula Theologica*, 1773, 8vo.

ERNESTI, Johann Christian Gottlieb (1756–1802), nephew of the preceding, a distinguished classical scholar and critic, was born at Arnstadt, Thuringia, in 1756. After attending the gymnasium of his native town, he entered the university of Leyden, where he had the advantage of his uncle's superintendence in his studies. He obtained his master's degree in 1777, but continued his studies till 1782. On the 5th June of that year he was made supplementary professor of philosophy at his native university; and on the death of his cousin, August Wilhelm, he was in 1802 elected professor of rhetoric. He died on the 5th June of the same year, having discharged his new professional duties for only five months.

His principal works are an edition of *Æsopi fabulæ Gr.* (1781), *Hesychii glossæ sacræ emendationibus notisque illustratæ* (1785), *Suidæ et Phavorini glossæ sacræ* (1786), *Silii Italici Punicorum Libri Septemdecim*, etc., 2 vols. (1791 and 1792), *Lexicon Technologiæ Græcorum rhetoricæ* (1795), *Lexicon Technologiæ Romanorum rhetoricæ* (1797), and *Cicero's Geist und Kunst* (1799–1802). He also edited some of his uncle's works.

ERNST, Heinrich Wilhelm (1814–1865), an eminent violinist and composer, was born at Brünn, in Moravia, in 1814. He received his musical education at the Conservatorium of Vienna, studying the violin under Joseph Boehm and Mayseder, and composition under Seyfried. At the age of sixteen he made a concert tour through various towns of south Germany, which was the means of establishing his reputation as a violinist of the highest promise. In 1832 he visited Paris, where he found a warm reception, and continued to reside for several years. During this period he formed that intimacy with Stephen Heller of which a permanent memorial has been left in their charming joint-compositions—the *Pensées Fugitives* for piano and violin. In 1843 he paid his first visit to London at the close of the musical season. The impression which he then made on a limited circle was more than confirmed during a longer residence in the following year, when his rare powers as a violinist were recognized by the general body of the musical public. Thenceforward he visited England nearly every year, until his health entirely broke down under the pressure of long continued neuralgic disease of a most severe kind, which frequently incapacitated him from the exercise of his art. The last seven years of his life were spent in retirement, chiefly at Nice, where he died on the 8th October, 1865. As a violinist Ernst was distinguished for his almost unrivalled executive power, for his loftiness of conception, and for his intensely passionate expression. As a composer he wrote chiefly for his own instrument, and his *Elegie* and *Otello Fantasia* rank among the most treasured works for the violin. Ernst was a man of a singularly generous nature, as was shown by the unfailing readiness with which he gave his services for the benefit of his brother artists.

EROS, in Greek mythology, Love or Desire. By later poets he is represented as a son of Zeus and Gaia (the Earth), or Aphrodite, or Artemis; but in the Hesiodic theogony he makes up, with Chaos, Gaia, and Tartarus, the number of self-existent deities, and as the most beautiful of all the gods he conquers the mind and will of both gods and men. The name Eros answers to the Vedic Arusha, a name applied to the sun, but only at his rising. Arusha, like the Greek Eros and the Latin Cupido, is spoken of as a child with beautiful wings.

ERPENIUS (original name, VON ERPE), THOMAS (1584–1624), a distinguished Orientalist, was born at Gorcum, in Holland, September 11, 1584. After completing his early education at Leyden, he entered the university of that city, and in 1608 took the degree of master of arts. By the advice of Scaliger he studied the Oriental languages whilst taking his course of theology; and he even then gave promise of great distinction in that department of learning. He afterwards travelled in England, France, Italy, and Germany, forming connections with learned men, and availing himself of the information which they communicated. During his stay at Paris he contracted a friendship with Casaubon, which lasted during his life, and also took lessons in Arabic from an Egyptian, Joseph Barbatus, otherwise called Abu-dakni. At Venice he perfected himself in the Turkish, Persic, and Ethiopic languages. After a long absence, Erpenius returned to his own country in 1612, and on the 10th February, 1613, he was appointed professor of Arabic and other Oriental languages, Hebrew excepted, in the university of Leyden. Soon after his settlement at Leyden, animated by the example of Savary de Brèves, who had established an Arabic press at Paris at his own charge, he caused new Arabic characters to be cut at a great expense, and erected a press in his own house. In 1619 the curators of the university of Leyden instituted a second chair of Hebrew in his favor. In 1620 he was sent by the States of Holland to induce Pierre Dumoulin or André Rivet to settle in that country; and after a second journey he was successful in inducing Rivet to comply with their request. Some time after the return of Erpenius, the States appointed him their interpreter; and in this capacity he had the duty imposed upon him of translating and replying to the different letters of the Moslem princes of Asia and Africa. His reputation had now spread throughout all Europe, and several princes, the kings of England and Spain, and the archbishop of Seville made him the most flattering offers; but he constantly refused to leave his native country. In addition to the numerous works he had already published, he was preparing an addition of the Koran with a Latin translation and notes, and was projecting an Oriental library, when at the early age of forty a contagious disease cut short his life, November 13, 1624.

Among his works may be mentioned his *Grammatica Arabica*, published originally in 1613, often reprinted, and still in use; *Rudimentæ linguæ Arabicæ* (1620); *Grammatica Ebræa generalis* (1621); *Grammatica Chaldaica et Syra*, 1628; and an edition of Elmacinus's *History of the Saracens*.

ERSCH, JOHANN SAMUEL (1766–1828), the founder of German bibliography, was born at Gross Glogau, in Prussian Silesia, June 23, 1766. In 1785 he entered the university of Halle with the view of studying theology, but very soon his whole attention became engrossed with history, bibliography, and geography. At Halle he made the acquaintance of Fabri, professor of geography; and when the latter was made professor of history and statistics at Jena, Ersch accompanied him thither, and aided him in the preparation of several works. He also devoted a large portion of his time to the acquisition of modern languages, and became a thorough proficient in French, Italian, English, Swedish, and Danish, and in their respective literatures. In 1788 he published the *Verzeichniss aller anonymischen Schriften*, as a supplement to the 4th edition of Meusel's *Gelehrtes Deutschland*. The researches required for this work suggested to him the preparation of a *Repertorium über die Allgemeinen Deutschen Journale und andere periodische Sammlungen für Erdbeschreibung, Geschichte, und die damit verwandten Wissenschaften* (Lemgo, 1790–92). The fame which this publication acquired him led to his being engaged by Schütz and Hufeland to prepare, in connection with their *Institut der allgemeinen Literaturzeitung*, an *Allgemeines Repertorium der Literatur*, published in 8 vols. (Jena and Weimar, 1793–1809), which condensed the literary productions of 15 years (1785–1800), and included an account not merely of the books published during that period, but also of articles in periodicals and magazines, and even of the criticisms to which each book had been subjected. While engaged in this great work he also projected *La France littéraire*, which was published at Hamburg in 5 vols., from 1797 to 1806. In 1795 he went to Hamburg to edit the *Neue Hamburger Zeitung*, founded by Victor Klopstock, brother of the poet, but returned in 1800 to Jena to take part in the preparation of the *Allgemeinen Literaturzeitung*. He also obtained in the same year the office of librarian in the university, and in 1802 was made professor of philosophy. In 1803 he accepted the chair of geography and statistics at Halle, and in 1808 was made principal librarian. He here projected a *Handbuch der Deutschen Literatur seit der Mitte des 18 Jahrh. bis auf die neueste Zeit* (Leip., 1812–14) and along with Gruber the *Allgemeine Encyklopädie der Wissenschaften und Künste*, which he continued as far as its 18th volume. He died at Halle 16th January, 1828.

ERSKINE, EBENEZER (1680–1754), the chief founder of the Secession Church (formed of dissenters from the Church of Scotland), was the son of the Rev. Henry Erskine, who at one time was minister at Cornhill, North Durham, but was ejected in 1662 by the Act of Uniformity, and, after suffering some years' imprisonment, was after the Revolution appointed to the parish of Chirnside, Berwickshire. Ebenezer was born on the 22d June, 1680, most probably at Dryburgh, Berwickshire, as his parents were residing there for the greater part of that year. He entered the university of Edinburgh in 1693, and took his M.A. degree in 1697. He was licensed to preach in 1702, and in the following year was settled in the parish of Portmoak, Kinross-shire. There he remained for twenty-eight years, after which, in the autumn of 1731, he was translated to the West Church, Stirling. Some time before this, he along with some other ministers was "rebuked and admonished" by the General Assembly for defending the doctrines contained in a book called the *Marrow of Modern Divinity*. A sermon which he preached on lay-patronage before the synod of Perth in 1733 furnished new grounds of accusation, and he was compelled to shield himself from rebuke by appealing to the General Assembly. Here, however, the sentence of the synod was confirmed, and after many fruitless attempts to obtain a hearing, he and three other ministers, Wilson, Moncrieff, and Fisher, were suspended from the office of the ministry by the commission in November of that year. Against this sentence they protested, and constituted themselves into a separate church court, under the name of the Associate Presbytery. It was not, however, till 1739 that they were again summoned before the Assembly, when appearing in their corporate capacity they declined the authority of the church, and were deposed in the following year. They received numerous accessions to their communion, and remained in harmony with each other till 1747, when a division took place in regard to the nature of the oath administered to burgesses. Erskine joined with the "Burgher" section, to whom he became professor of theology. He continued also to preach to a numerous congregation in Stirling till his death, which took place on the 2d June, 1754. Erskine was a very popular preacher, and a man of considerable force of character; and whatever opinion may be held as to his disputes with the Church of Scotland, it must be admitted that he acted throughout with an honesty and courage which are worthy of all respect. The Burgher and Anti-Burgher sections of the Secession Church were reunited in 1820, and in 1847 they united with the Relief Synod in forming the United Presbyterian Church. Erskine's published works consist chiefly of sermons. His *Life and Diary*, edited by the Rev. Donald Fraser, was published in 1840.

ERSKINE, John, of Carnock (1695–1768), an eminent writer on the law of Scotland and professor in the university of Edinburgh, was born in 1695. His father, Lieutenant-Colonel John Erskine, son of Henry, second Lord Cardross, was a noted Whig and zealous Presbyterian, who made himself conspicuous at the Revolution by refusing to take the oath of abjuration notwithstanding his strong attachment to King Wllliam. John Erskine the younger was admitted a member of the faculty of advocates in 1719. Although he never enjoyed much practice at the bar, he acquired a high reputation as a sound and learned lawyer. In 1737 he was appointed professor of Scots law in the university of Edinburgh—a position which he proved to be peculiarly well fitted to adorn. In 1754 he published his *Principles of the Law of Scotland*. He retired from his chair in 1765; and during the remainder of his uneventful life he occupied himself with the preparation of his great work, the *Institute of the Law of Scotland*, which he did not live to publish. He died at Cardross on the 1st March, 1768.

Erskine's *Institute*, although it does not exhibit the grasp of principle which distinguished his great predecessor Lord Stair, is so conspicuous for learning, accuracy, and sound good sense, that it has always been esteemed of the highest authority on the law of Scotland. On one important branch indeed—commercial law—it is very defective, even when compared with Lord Stair's much earlier work; but at the time when Erskine wrote commerce had declined in Scotland, while the forfeitures consequent on the rebellions of 1715 and 1745 had given a great impetus to feudal conveyancing; and the *Institute* naturally reflects this state of society. Nor does it profess to give a very extended exposition of criminal law; but on all the other branches of Scottish jurisprudence it is, even at the present day, the most trustworthy guide which the student can find. The *Principles*, although published first, is substantially an abridgment of the larger work, and is in some respects superior to it. More concise and direct, it gives an admirable exposition of the main principles of the law in a perspicuous and interesting manner. It was designed to supersede Sir George Mackenzie's *Institutions* as the class text-book; and it is a conclusive proof of its excellence that it still retains this place in the university.

The *Institute* first appeared in 1773, and has repeatedly been republished. The best edition is the last (1871), by Mr. Badenach Nicolson, who has preserved the valuable and authoritative notes of Lord Ivory's edition (1824-28). The last (15th) edition of the *Principles* is admirably edited by Mr. Guthrie (1874).

ERSKINE, John, D.D. (1721–1803), son of the above, a minister of the Church of Scotland, was born on the 2d June, 1721. It was his early desire to enter the church; and although, in deference to his father's wish, he studied law for a time after completing his course in arts at the university of Edinburgh, he was eventually permitted to follow his own inclination. He was licensed to preach by the presbytery of Dunblane in 1743; and in May of the following year he was ordained minister of the important parish of Kirkintilloch, near Glasgow. In 1753 he was translated to Culross, in Fifeshire, from which he was removed in 1758 to the New Greyfriars Church in Edinburgh. In 1767 this was exchanged for the collegiate charge of the Old Greyfriars Church, where he became the colleague of Principal Robertson, the historian. Here he remained until his death, which took place on January 19, 1803. His writings consist chiefly of numerous controversial pamphlets on theological subjects, and their contents make it a matter of regret that he did not publish something which was the result of more extended labor. He carried on an extensive correspondence with many distinguished men in England, on the Continent, and in America. His sermons are clear, vigorous expositions of a moderate Calvinism, in which metaphysical argument and practical morality are happily blended. In church politics he was the leader of the evangelical party; but his high character and the benignity of his disposition secured for him the esteem of his opponents and the friendship of their leader, his colleague Dr. Robertson. There is an excellent Life of Erskine by Sir H. Moncrieff Welwood (Edin. 1818), the appendix to which contains a complete list of his numerous writings.

ERSKINE, Ralph (1685–1752,) brother of Ebenezer Erskine, was born 18th March, 1685. After studying at the university of Edinburgh, he was licensed as a preacher in 1709, and in 1711 was ordained as assistant minister at Dunfermline. He homologated the protests which his brother laid on the table of the Assembly after being rebuked for his synod sermon, but he did not formally withdraw from the Establishment till 1737. He was also present, though not as a member, at the first meeting of the Associate Presbytery. When the severance took place on account of the oath administered to burgesses, he adhered, along with his brother, to the Burgher section. He died after a short illness on November 6, 1752. His works consist of sermons, poetical paraphrases, and gospel sonnets. The *Gospel Sonnets* have frequently appeared separately. His *Life and Diary*, edited by the Rev. D. Fraser, was published in 1842.

ERSKINE, Thomas, Baron (1750–1823), probably the greatest forensic orator that Britain has produced, was the third and youngest son of Henry David, tenth earl of Buchan, and was born in Edinburgh on the 10th of January, 1750. From an early age he showed a strong desire to enter one of the learned professions; but his father, whose means had barely permitted him to afford the expense of a liberal education for his two elder sons—one of whom, afterwards the well-known Harry Erskine, was studying for the Scotch bar—was unable to do more than give him a good school education at the High School of Edinburgh and the grammar school of St. Andrews. He attended the university of St. Andrews for one session, after which it was decided that he should join the navy; and in the spring of 1764 he left Scotland to serve as a midshipman on board the "Tartar." His buoyancy of spirit and the opportunity for study which he had on board a man-of-war reconciled him to his new mode of life; but on finding, when he returned to this country after four years' absence in North America and the West Indies, that there was little immediate chance of his rank of acting lieutenant being confirmed, he resolved to quit the service. He entered the army, purchasing a commission in the 1st Royals with the meagre patrimony which had been left to him. But promotion here was as slow as in the navy; while in 1770 he had added greatly to his difficulties by marrying the daughter of Mr. Daniel Moore, M.P. for Marlow, an excellent wife, but as poor as himself. In these depressing circumstances he happened to be quartered where the assizes were being held, and lounging into court one day was invited to the bench by his father's old friend Lord Mansfield. He was told that the barristers who were pleading were at the top of their profession, yet he felt that he could do as well, if not better, himself. He confided his plan to Lord Mansfield, who did not discourage him, and to his mother, a woman of remarkable determination of character, who strongly advised him to quit the army for the law. Accordingly on the 26th April, 1775, he was admitted a student of Lincoln's Inn. He also on the 13th January following entered himself as a gentleman commoner on the books of Trinity College, Cambridge, but merely that by graduating he might be called two years earlier. He placed himself as a pupil under Mr. Buller, and, when that eminent lawyer was elevated to the bench, under Mr. (afterwards Baron) Wood, and was called to the bar on the 3d July, 1778. His success was immediate and brilliant. An accident was the means of giving him his first case, Rex *v.* Baillie, in which he appeared for Captain Baillie, the lieutenant-governor of Greenwich Hospital, who had published a pamphlet animadverting in severe terms upon the abuses which Lord Sandwich, the first Lord of the Admiralty, had introduced into the management of the hospital, and against whom a rule had been obtained from the Court of King's Bench to show cause why a criminal information for libel should not be filed. Erskine was the junior of five counsel; and it was his good fortune that the prolixity of his leaders consumed the whole of the first day, thereby giving him the advantage of starting afresh next morning. He made use of this opportunity to deliver a speech of wonderful eloquence, skill, and courage, which captivated both the audience and the court. The rule was discharged, and Erskine's fortune was made. He received, it is said, thirty retainers before he left the court. In 1781 he delivered another remarkable speech, in defence of Lord George Gordon—a speech which gave the death-blow to the doctrine of constructive treason. In 1783, when the Coalition Ministry came into power, he was returned to parliament as member for Portsmouth. His first speech in the House of Commons was a failure; and he never in parliamentary debate possessed anything like the influence he had at the bar. He lost his seat at the dissolution in the following year, and remained out of parliament until 1790, when he was again returned for Portsmouth. But his success at the bar continued unimpaired. In 1783 he received a patent of precedence. His first special retainer was in defence of Dr. Shipley, dean of St. Asaph, who was tried in 1784 before Mr. Justice Buller at Shrewsbury for seditious libel—a case memorable for Erskine's bold yet dignified vindication of the independence of the bar, and for the speech which he subsequently made before the court at Westminster against a motion for a new trial. In 1789 he was counsel for Stockdale, a bookseller, who was charged with seditious libel in publishing a pamphlet in favor of Warren Hastings, whose trial was then proceeding, and his speech on this occasion, probably his greatest effort, is a consummate specimen of the art of addressing a jury. Three years afterwards he brought down the opposition alike of friends and foes by defending Thomas Paine, author of *The Rights of Man*—holding that an advocate has no right, by refusing a brief, to convert himself into a judge. As a consequence he lost the office of attorney-general to the Prince of Wales, to which he had been appointed in 1786; the prince, however, subsequently made amends by making him his chancellor. Among Erskine's later speeches may be mentioned those for Horne Tooke and the other advocates of parliamentary reform, and that for Hadfield, who was accused of shooting at the king. On the accession of the Grenville ministry in 1806, he was made lord chancellor, an office for which his training had in no way prepared him, but which he fortunately held only during the short period his party was in power. Of the remainder of his life it would be well if nothing could be said. Occasionally speaking in parliament, and hoping that he might return to office should the prince become regent, he gradually degenerated into a state of useless idleness. Never conspicuous for prudence, he aggravated his increasing poverty by an unfortunate second marriage. Once only—in his conduct in the case of Queen Caroline—does he recall his former self. He died at Almondel, Linlithgowshire, 17th November, 1823, of inflammation in the chest, caught on the voyage to Scotland.

Erskine no doubt owed much to the period in which he lived. In another age his highest distinction would probably have been the barren and evanescent reputation of a successful verdict-getter. The political trials in which he was engaged not only handed him down to posterity as the vindicator of his country's liberties, but by inspiring him with the consciousness that he was defending his country and its constitution as much as if he were speaking in parliament or fighting in the field, developed, in a way that no ordinary trial could have done, that impassioned eloquence and undaunted courage which so often carried audience and jury and even court along with him. As a judge he did not succeed; and it has been questioned whether under any circumstances he could have succeeded. For the office of chancellor he was plainly unfit; but it is difficult to believe that one who for so long was the ornament of the bar of the King's Bench could have presided over that court without adding fresh lustre to his name. As a lawyer he was well read, but by no means profound. His strength lay in the keenness of his reasoning faculty, in his dexterity and the ability with which he disentangled complicated masses of evidence, and above all in his unrivalled power of fixing and commanding the attention of juries. To no department of knowledge but law had he applied himself systematically, with the single exception of English literature, of which he acquired a thorough mastery in early life, at intervals of leisure in college, on board ship, or in the army. Vanity is said to have been his ruling personal characteristic; but those who knew him, while they admit the fault, say that in him it never took an offensive form, even in old age, while the singular grace and attractiveness of his manner endeared him to all with whom he came in contact.

In 1772 Erskine published *Observations on the Prevailing Abuses in the British Army*, a pamphlet which had a large circulation, and in later life, *Armata*, an imitation of Gulliver's Travels. His most noted speeches have repeatedly appeared in a collected form. There is a good account of his life in Lord Campbell's *Chancellors*, and an interesting estimate of his character in Lord Abinger's recently published *Memoir*.

(H. J. E. F.)

ERSKINE, Thomas, of Linlathen (1788–1870), a writer on theology and religion, son of David Erskine, writer to the signet in Edinburgh, and of Anne Graham, of the Grahams of Airth, was born 13th October, 1788. He was a descendant of the earl of Mar, regent of Scotland in the reign of James VI., a grandson of John Erskine of Carnock, and a nephew of the Rev. Dr. John Erskine, both noticed above. After being educated at the High School of Edinburgh and at Durham, he attended the literary and law classes at the university of Edinburgh; and becoming in 1810 a member of the Edinburgh faculty of advocates, he for some time enjoyed the intimate acquaintance of Cockburn, Jeffrey, Scott, and the other distinguished men whose talents then lent an unusual lustre to the Scotch bar. On the death of his elder brother in 1816 he succeeded to the family estate of Linlathen, near Dundee, and retired from the bar—occupying the chief portion of his subsequent life in the management of his estate, in the intercourse of a few select friends, and in the discussion—either by conversation, by letters, or by literary publications—of those religious topics which he considered to have a vital relation to man's highest welfare. The writings of Erskine are perhaps deficient in robustness of thought, but they are clothed in a graceful style, and possess a certain originality and interest, due chiefly to his strong earnestness, unaffected sincerity, and fine moral insight. His theological views have a considerable similarity to those of Frederick Denison Maurice, who acknowledges having been indebted to him for his first true conception of the meaning of Christ's sacrifice. Erskine had little interest in the "historical criticism" of Christianity, and regarded as the only proper criterion of its truth its conformity or non-conformity with man's spiritual nature, and its adaptability or non-adaptability to man's universal and deepest spiritual needs. He considered the incarnation of Christ as the necessary manifestation to man of an eternal sonship in the divine nature, apart from which those filial qualities which God demands from man could have no sanction; and by *faith* as used in Scripture he understood to be meant a certain moral or spiritual condition which virtually implied salvation, because it implied the existence of a principle of spiritual life possessed of an immortal power. This faith, he believed, could be properly awakened only by the manifestation, through Christ, of love as the law of life, and as identical with an eternal righteousness which it was God's purpose to bestow on every individual soul. During the last 33 years of his life Mr. Erskine did not engage in any literary efforts. He spent the summer generally at Linlathen, and the winter either at Edinburgh, Paris, Geneva, or Lausanne. On the Continent he enjoyed the society of, among others, Mme. Vernet, the duchess de Broglie, the younger Mme. de Staël, and M. Vinet of Lausanne, and among his most intimate friends in this country were Edward Irving, Frederick Maurice, Dean Stanley, Bishop Ewing, Dr. John Brown, and Thomas Carlyle. He exercised considerable influence over the whole circle of his acquaintance by his unassuming earnestness in advocating his religious views, and by the rare qualities of his personal character. He died at Edinburgh 20th March, 1870.

His principal works are *Remarks on the Internal Evidence for the Truth of Revealed Religion* (1820), an *Essay on Faith* (1822), and the *Unconditional Freeness of the Gospel* (1828). These have all passed through several editions, and have also been translated into French. He is also the author of the *Brazen Serpent* (1831), the *Doctrine of Election* (1839), several "Introductory Essays" to editions of *Christian Authors*, and a posthumous work entitled *Spiritual Order and Other Papers* (1871). Two vols. of his letters, edited by William Hanna, D.D., with reminiscences by Dean Stanley and Principal Shairp, appeared in 1877.

ERYSIPELAS (a Greek word, ἐρυσίπελας, probably derived from ἐρυθρός, and πέλλα, skin)—synonyms, *the Rose, St. Anthony's Fire*—a disease characterized by diffuse inflammation of the skin, attended with fever. Two kinds of this disorder are recognized, namely,—*traumatic* erysipelas, which occurs in connection with some wound or external injury, and may thus affect any part of the body where such lesion may exist; and *idiopathic* erysipelas, in which no connection of this kind can be traced, but which appears to arise spontaneously, and most commonly affects the face and head. They are, however, essentially the same disease, and, as regards the latter variety, it is believed by some authorities that an abrasion of the skin, generally too trifling to attract attention, exists in almost every case as the starting-point of the inflammatory action.

The question as to whether erysipelas is to be regarded as an eruptive fever allied to scarlet fever, measles, etc., or a local inflammatory disease of the skin, the fever being secondary, has engaged much attention; and while the weight of opinion appears to be in favor of the latter view, the facts of the contagiousness of erysipelas, its occasional appearance in an epidemic form, and the discovery in the inflamed tissues of microscopic organisms (*Bacteria*) point to the existence of a specific poison as giving peculiar characters to this form of cutaneous inflammation. The contagiousness of erysipelas in its traumatic form is often illustrated in the surgical wards of hospitals, where, having once broken out, it is apt to spread with great rapidity, and to produce disastrous results, as well as in lying-in hospitals, where its occurrence gives rise to the spread of a form of puerperal fever of virulent character. It is not so certain that the disease in its idiopathic variety is contagious to persons who have no wound or abrasion, and this form of the complaint is in general excited by exposure to cold, a predisposing cause being some deranged or low condition of the general health.

When the erysipelas is of moderate character there is simply a redness of the integument, which feels somewhat hard and thickened, and upon which there often appear small vesications. This redness, though at first circumscribed, tends to spread and affect the neighboring sound skin, until an entire limb or a large area of the body may become involved in the inflammatory process. There is usually considerable pain, with heat and tingling in the affected part. As the disease advances the portions of skin first attacked become less inflamed, and exhibit a yellowish appearance, which is followed by slight desquamation of the cuticle. The inflammation in general gradually disappears. Sometimes, however, it breaks out again, and passes over the area originally affected a second time. But besides the skin, the subjacent tissues may become involved in the inflammation, and give rise to the formation of pus. This is termed *phlegmonous erysipelas*, and is much more apt to occur in connection with the traumatic variety of the disease. Occasionally the affected parts become gangrenous. Certain complications are apt to arise in erysipelas affecting the surface of the body, particularly inflammation of serous membranes, such as the pericardium, pleura, and peritoneum.

Erysipelas of the face, the most common form of the idiopathic variety, usually begins with symptoms of general illness, the patient feeling languid, drowsy, and sick, while frequently there is a distinct rigor followed with fever. According to some observers, the fever is symptomatic of inflammation already begun in the neighboring lymphatic vessels and glands before the appearance of the disease on the skin. Sore throat is sometimes felt, but in general the first indication of the local affection is a red and painful spot at the side of the nose or on one of the cheeks or ears. Occasionally it would appear that the inflammation begins in the throat, and reaches the face through the nasal fossæ. The redness gradually spreads over the whole surface of the face, and is accompanied with swelling, which in the lax tissues of the cheeks and eyelids is so great that the features soon become obliterated and the countenance wears a hideous expression. Advancing over the scalp, the disease may invade the neck and pass on to the trunk, but in general the inflammation remains confined to the face and head. While the disease progresses, besides the pain, tenderness, and heat of the affected parts, the constitutional symptoms are very severe. The temperature rises often to 105° or higher, and there is great gastric disturbance. Delirium is a frequent accompaniment. The attack in general lasts for a week or ten days, during which the inflammation subsides in the parts of the skin first attacked, while it spreads onwards in other directions, and after it has passed away there is, as already observed, some slight desquamation of the cuticle.

Although in general the termination is favorable, serious and occasionally fatal results follow from inflammation of the membranes of the brain, and in some rare instances sudden death has occurred from suffocation arising from œdema glottidis, the inflammatory action having spread into and extensively involved the throat. One attack of this disease, so far from protecting from, appears rather to predispose to others; and this fact is appealed to by those physicians who deny that erysipelas is merely one of the eruptive fevers—such disorders, as is well known, rarely occurring a second time in the same individual.

Erysipelas occasionally assumes from the first a violent form, under which the patient sinks rapidly, and instances are on record where such attacks have proved disastrous to several persons who had been exposed to their contagion. It is sometimes a complication in certain forms of exhausting disease, such as consumption or typhoid fever, and is then to be regarded as of serious import. A very fatal form occasionally attacks new-born infants, particularly in the first four weeks of their lives. In epidemics of puerperal fever this form of erysipelas has been specially found to prevail.

The treatment of erysipelas is best conducted on the expectant system. The disease in most instances tends to a favorable termination; and beyond attention to the condition of the stomach and bowels, which may require the use of some gentle laxative, little is necessary in the way of medicine. The employment of preparations of iron in large doses is strongly recommended by many physicians. But the chief point is the administration of abundant nourishment in a light and digestible form. Of the many local applications which may be employed, hot opiate fomentations, such as a decoction of poppy heads, will be found among the most soothing. Dusting the affected part with flour or powdered starch, and wrapping it in cotton wadding, is also of use; or collodion may be painted over the inflamed surface to act as a protective.

With the object of preventing the spread of the inflammation, lines drawn with some caustic material (such as common lunar caustic) beyond the circumference of the inflamed part have been supposed to be of use, but this plan often fails. In the case of phlegmonous erysipelas complicating wounds, free incisions into the part are necessary. (J. O. A.)

ERYTHRÆ, one of the Ionian cities of Asia Minor, was situated on a small peninsula stretching into the Bay of Erythræ, at an equal distance from the mountains Mimas and Coryeus, and directly opposite the island of Chios. In the peninsula excellent wine was produced. From the fact that, in the naval battle fought by the Ionian confederates before Miletus in 494 B.C., the Erythræans had only eight ships engaged, it is conjectured that Erythræ could not have been a city of much importance. The Erythræans appear to have owned for a considerable time the supremacy of Athens, but towards the close of the Peloponnesian war they threw off their allegiance to that city. Erythræ was the birthplace of two prophetesses—one of whom, Sibylla, is mentioned by Strabo as living in the early period of the city; the other, Athenais, lived in the time of Alexander. The site of the city has been accurately ascertained, and considerable remains of its most important buildings—including the acropolis, the theatre, and what is thought to be the ancient temple of Hercules—have been discovered at the modern Ritri.

ERYX, an ancient city and mountain in the west of Sicily, six miles from Drepana, and a short distance from the sea shore. On the summit of the mountain stood a celebrated temple of Venus, called from that circumstance Erycina, under which name the goddess is frequently mentioned by the Latin poets. See MONTE S. GIULIANO.

ERZEROUM, ERZRUM, or sometimes ARZEROUM, an important town of Turkish Armenia, at the head of an extensive vilayet of the same name, the residence of a pasha, and the seat of an Armenian patriarch and a Greek bishop, as well as the centre of the fourth army corps, and one of the main strategical points on the Turko-Russian frontier.

It is situated 6200 feet above the level of the sea on the southern edge of a wide valley, surrounded by mountains of considerable elevation, about 4 miles from the Kara-Su or western branch of the Euphrates, 140 miles S.S.E. of Trebizond. To the east lies the Devi-Boyun, upwards of 8000 feet in height, and to the south-east the Polan-Duken, the latter being the birthplace of a number of small streamlets, which, after meeting in the town, flow N. to the Kara-Su. The streets of the town are for the most part irregular, unpaved, badly drained, filthy, and infested with dogs; and as the building material is mainly a dark-gray volcanic stone cemented with mud, the general appearance is dull and sombre. The roofs, with scarcely an exception, are flat or dome-shaped, and covered with a layer of earth and sward, on which it is no uncommon thing to see a donkey grazing. A considerable proportion, indeed, of the ordinary dwelling-houses are formed by making an extensive quadrangular excavation in the earth, and covering in the whole or a part of the area, so that the roof is almost on a level with the natural surface of the ground. The town is said to contain about thirty khans or caravansaries, about as many mosques, a number of Christian churches, and nineteen public baths; but none of these buildings are of much architectural pretension, except the Armenian cathedral and the Shifteh—two graceful minarets near the citadel, belonging to an ancient and striking edifice, of which a detailed account may be found in Hamilton's *Researches in Asia*, 1842. A large number of circular towers with conical tops give a certain picturesqueness to the general view; they are popularly reputed to be the tombs of holy men who died in the 14th century. The defences consist of an old brick-built citadel near the centre of the town, an enceinte on Vauban's principles with dry ditch and dilapidated walls, several detached forts constructed since 1864, and a number of outlying earthworks of no great strength. The outer wall of the citadel having fallen into disrepair has been demolished. An excellent supply of water from Polan-Duken is distributed by wooden pipes to numerous fountains. Situated as it is on the main route between the Black Sea and Persia, Erzeroum has long maintained an extensive trade; and though on account of the unsettled state of the country its commercial prosperity has declined since 1830, Persia, England, Russia, and Germany think it worth while to maintain consular agents in the town. The exports are wheat, goat and sheep skins, mohair, and a lessening quantity of galls; and tobacco from Persia, known as *timbaki*, furs from Russia, and Manchester goods are among the main items of the transit trade. Since 1860 the road from Trebizond has been greatly improved, and four-wheeled fourgons accomplish the distance in eight or nine days. The principal trades are tanning, morocco-dyeing, sheep skin dressing, and the making of horse-shoes, nails, and iron, brass, and copper utensils. In 1873 a building was erected by two Armenian Catholics, Shabanian by name, to be used as a distillery, soap-works, and a macaroni manufactory. A considerable number of the townspeople are owners of sheep-farms or flocks in the mountain pastures; and a still greater proportion keep sheep and cattle in the town, sending them out daily under the charge of a common herdsman. To a stranger it is a remarkable sight to watch the regularity with which, as the herdsman passes in the morning, the separate flocks and herds join the main body, and the equal regularity with which in the evening they turn aside to their respective quarters. The climate is exceedingly severe, and snow lies on the ground for about six months in the year. As wood is scarce the usual fuel is tezek or dry cow-dung, the preparation of which is one of the most important tasks of the farmer-citizen. In 1854 the population of Erzeroum was estimated at 50,000, of whom 30,000 were Turks, 5000 Orthodox Armenians, 2300 Catholic Armenians, 1200 Persians, 300 Greeks, 1200 Armenians, Georgians, and Jews claiming to be Russian subjects, and 10,000 soldiers. More recent estimates give 100,000, 60,000, and 50,000.

Erzeroum is a town of great antiquity, and has been identified with the Armenian Garin Khalakh, the Arabic Kalikalah, and the Byzantine Theodosiopolis of the 5th century. Its present name, by some regarded as a corruption of *Arx Romanorum*, the "citadel of the Romans," is more probably derived from Arsen-er-Rum, seeing that Arsen is known to have been the name of a town in the immediate vicinity. At the time of its capture by the Seljuks in 1201 Erzeroum must have been a mighty city, if the statement that it lost 140,000 of its inhabitants forms even an approximation to the truth. It came into Turkish possession in 1517. On July 9, 1829, it was captured by the Russian general Paskevitch, and the Russian occupation continued till the peace of Adrianople, 14th September. In 1859 a severe earthquake occurred, by which about 4500 houses were destroyed, 9 minarets levelled with the ground, and about 500 people killed. After suffering greatly from disease and death, the town capitulated to the Russians in February, 1878.

See Curzon, *Erzeroum and Armenia;* Flandin and Coste, *Voyage en Perse*, Paris, 1851; Monteith, *Erzeroum and Kars*, 1856; Williams, *War Diary*, 1877; C. B. Norman, *Armenia and the Campaign of 1877.*

ERZGEBIRGE, a mountain chain of Germany, forming the boundary between Saxony and Bohemia, and extending in a W.S.W. direction from the Elbe to the Fichtelgebirge, where the White Elster has its source. Its length from E.N.E. to W.S.W. is over 100 miles, and its average breadth about 25 miles. The southern declivity is generally steep and rugged, forming in some places an almost perpendicular wall of the height of from 2000 to 2500 feet; while the northern, divided at intervals into valleys, sometimes of great fertility and sometimes wildly romantic, slopes gradually towards the great plain of Northern Germany. The central part of the chain forms a plateau of an average height of more than 3000 feet. At the extremities of this plateau are situated the highest summits of the range:—in the south-east, Keilberg (4000 feet); in the north-east, Fichtelberg (3980 feet); and in the south-west, Spitzberg (3650 feet). Near Spitzberg, at the height of about 3300 feet, is situated Gottesgabe, the highest town in Germany. Geologically, the Erzgebirge range consists mainly of gneiss, mica, and phyllite. As its name indicates, it is famous for its mineral ores. These are chiefly silver and lead, the layers of both of which are very extensive, tin, nickel, copper, and iron. Gold is found in several places, and some arsenic, antimony, bismuth, manganese, mercury, and sulphur.

ESARHADDON (Assur-akhi-iddina, "Assur gave brothers") succeeded his father Sennacherib as king of Assyria, January, 680 B.C. He had had to fight a battle a few weeks previously against his elder brothers, Adrammelech and Nergal-sharezer, who had murdered their father, and after their defeat fled to Armenia. The murder had probably been occasioned by the partiality shown by Sennacherib for Esarhaddon, a curious record of which has been preserved to us in a kind of will in which he bequeaths to Esarhaddon various private property. Esarhaddon seems to have been the ablest of the Assyrian monarchs; he was distinguished equally as a general and an organizer, and under him the Assyrian empire attained almost its farthest limits. His character, too, seems to have been milder than that of most other Assyrian kings, and his policy was one of conciliation. Babylon, which had been destroyed by Sennacherib in 691 B.C., was rebuilt, and made the southern capital. It was to Babylon, therefore, that Manasseh was brought (2 Chr. xxxiii. 11). Esarhaddon's first object was to strengthen his empire by overthrowing the rival monarchy of Egypt, and diverting the trade of Phœnicia to Nineveh. Zidon was accordingly razed to the ground, and the Assyrian arms carried as far as Cyprus; Tyre and Carchemish, however, rather than Nineveh, profited by the event. Egypt, then under the Ethiopian Tirhakah, was invaded, the Assyrians being supplied with water during their march across the desert by the king of the Arabians. Memphis and its treasures were captured, and Egypt as far as Thebes was made an Assyrian province, and divided into twenty satrapies. These twenty satrapies Herodotus has turned into a dodecarchy, and connected with the twelve courts of the Labyrinth built centuries before. The conquest of Egypt had been preceded by two important campaigns. One was against the Minni and the Medes, which secured the north-eastern frontier of the empire; the other was an expedition which penetrated into the heart of Arabia, and reflected the highest credit on the enterprise and military genius of the Assyrian monarch. His armies marched a distance of about 900 miles into the desert, traversing Uz and Buz (*Khazu* and *Bazu*), and reducing a large number of Arab tribes to subjection. The object of both these campaigns was clearly the same,—to spread terror among the barbarous tribes on the frontiers, and to prevent them from harassing the Assyrian provinces. Early in his reign

Esarhaddon had checked the southward march of the Gimirrai, or Cimmerians, who had been driven from their old seats on the Volga by the Scyths. He defeated them under a chief named Teuspa (? Teispes) in Khupuscia (near Colchis), and drove them westward across the Halys towards Sinope. About the same time Cilicia and the Dahæ were subdued, as well as Eden, or Tel-Assur, south-east of Assyria. Egypt had been aided in its struggle against Esarhaddon by Tyre, which had revolted from Assyria in spite of the favor shown to it. The town was at once blockaded; and the siege was still continuing when Esarhaddon died, in 668 B.C., after a reign of thirteen years, leaving behind him four sons and one daughter. Two years previously, just after his return from the Egyptian campaign, he had associated his son Assur-bani-pal, or Sardanapalus, in the government. The fact was announced to an assembly of the people on the 12th day of Iyyar, or April.

ESAU, or EDOM, the father of the Edomites, was the son of Isaac and Rebecca, and the elder twin brother of Jacob. According to the narrative contained in Genesis, the name Esau (hairy) was given to him on account of his hairy appearance at his birth, and the name Edom (red) when he sold his birthright to Jacob for a meal of red lentile pottage. Esau, who was a hunter, having returned famished from the chase, found Jacob enjoying a savory dish, and besought him to be allowed to share it. Jacob refused this, unless Esau made over to him the privileges of the elder son; and, prompted by the pangs of hunger, the latter immediately consented. Notwithstanding this, and although by marriage with two Canaanitish women Esau had separated himself from the pure blood of Abraham, he would have received the covenant blessing from his father, had not Jacob secured it through the deceit of personating Esau, which, as his father was blind, he was able to accomplish by imitating the hairy appearance of his brother by means of goat skins. Esau, on hearing what Jacob had done, vowed to kill him, and the latter found it necessary to flee to Mesopotamia. Soon afterwards Esau, to propitiate his parents, married the daughter of Ishmael, but as they continued to be offended by the idolatrous practices of his Canaanitish wives, he retired from his father's house and took up his residence in Mount Seir. Here he learned that Jacob was returning from Padanaram with his wives, children, and flocks; but, whether propitiated by the humble bearing of the latter or not, he not only refrained from executing the vengeance he had sworn against him, but even offered to escort him on his way. The two brothers afterwards united in burying their father; but after that Esau "took all his substance which he had got in the land of Canaan, and went into the country from the face of his brother Jacob." Some modern critics regard the history of Jacob and Esau as in a great degree, if not altogether, mythical, and the recorded life of Esau, as suggested very much by the nature of the country inhabited by his descendants, its history, and the relation of its inhabitants to those of Canaan. The words "Esau" and "Seir" etymologically suggest a shaggy mountain land. According to Ewald (*Gesch. d. V. Isr.* i. 336, 430, 494), the three names Seir, Edom, Esau, indicate that an aboriginal race calling itself Seir was first subjugated by Canaanites bearing the name of Edom, and then both Seir and Edom by Hebrews bearing the name of Esau. Esau in its turn was compelled to yield to a younger branch of the same race, inferior in physical strength but superior in certain moral qualities. The Phœnicians have a parallel legend about their progenitor Hypsuranius and the aboriginal Usous (Esau).

ESCHATOLOGY, or the "doctrine of last things," is a theological term for the facts revealed in Scripture about a future state, and the result of Christian speculation on these facts.

The origin of the term is to be found in the phrases "the last day," "the last times," and similar expressions adopted by New Testament writers from ancient prophecy.[1] It was the universal feeling among primitive Christians that they were living in the last period of the world's history. Their conflict with surrounding paganism constituted the final struggle between good and evil,[2] and would be ended by the appearance of Christ in visible triumph. The feeling was natural, and not new. The Jews always believed that the Messianic kingdom would be preceded by an unusual manifestation of the hostile powers of heathenism.[3] In times of great national distress the excess of misery was regarded as a sign of approaching deliverance; and the hopes of the nation were revived and its courage sustained by apocalyptic visions, in which the future was depicted as a time of undisputed triumph and unending prosperity. A distinct class of literature—of which the prophecies of Ezekiel and Zechariah afford partial examples—grew out of this feeling, and from it has been mainly derived the form, not only of Jewish, but also of Christian eschatology.

The central point of expectation having necessarily shifted, for those who received Jesus as the Messiah, from the first to the second advent, this event forms the focus of the Christian doctrine of last things. The expressions common among the Hebrews to denote respectively the existing and the coming dispensations—*αἰὼν οὗτος*, "this age,"[4] *αἰὼν μέλλων*, "the coming age"—were adopted, with a new reference. They became "this life" and "the life to come," and in later language "time" and "eternity;" and the *αἰών*, or age, became confused with the *κόσμος*,[5] or visible order of things. With the momentous epoch that formed the dividing-point between these two periods remained associated all that ancient prophecy connected with the restoration of the Hebrew monarchy. The apocalyptic literature which began with the book of Daniel, and which belongs to the post-exile period, had, it is true, already changed the form of the primitive national hopes. The restoration had become the resurrection; the idea of judgment had been enlarged to include the dead; and the final consummation was depicted, not as a mere distinction of the heathen or their subjugation to Judaism, but as a universal catastrophe in which all who had ever lived would have their part. But the mode of presentation had not changed, and the old prophetic language was literally adopted, although the sphere of its application had so infinitely extended.

Christian eschatology, then, is especially occupied with the destinies of the church in the concluding act of the world's drama. In formal treatises which trace the historical development of the opinion on the last things, they are usually arranged under the heads—Second Advent, Millennium, Resurrection, Judgment, Conflagration of the World, and the State of the Blessed and the Damned.

But experience taught the first generation of Christians to postpone the moment of the realization of their hopes. The second advent—which, however, as the fourth gospel teaches, had already been spiritually realized—was delayed. Already when St. Paul wrote to the Thessalonians, some had died before the fulfilment of their desire, and the church was troubled with fears lest they should awake from the death-sleep too late for the divine appearing. A new epoch was therefore introduced. The destinies of the individual from the moment of departure from this life enter into the inquiry, and the already boundless field of speculation is increased by the addition of controversies about an intermediate state, purgatory, and the limboes[6] into which the schoolmen partitioned hell. Nor is the area of theory substantially narrowed for Protestant theology, although it limits the last things to four—death, resurrection, judgment, end of the world, or more commonly, in practical discourses, to death, judgment, heaven, and hell.

The history of eschatology is in great measure the history of "lawless and uncertain thoughts" on these matters. The best notion of the extravagances allowed to speculation is obtained by a glance at the concluding part of the *Summa Theologiæ*, where Aquinas discusses these subjects. Thirty questions (besides an appendix devoted to purgatory) are proposed, each question being divided into several articles, and each article supported and opposed by many arguments. Then follows a conclusion, with the doctor's remarks on his conclusion. We take a few of the propositions at random:—"Whether souls are conducted to heaven or to hell immediately after death;" "Whether the limbus of hell is the same as Abraham's bosom;" "Whether the limbus puerorum is the same as the limbus patrum;" or, passing over a few pages, "Whether the sun and moon will be really obscured at the day of judgment;" "Whether the fire which is to purge the world will be like in kind to elemental fire;" or again, "Whether all the members of the human body will rise with it;" "Whether the hair and nails will reappear;" and so on to questions of age, size, and sex.[1]

[1] *ἐν τῇ ἐσχάτῃ ἡμέρᾳ*, John vi. 39; *ἐπ ἐσχάτων τῶν χρόνων*, 1 Pet. i. 20, etc.; *cf. τὰ ἔσχατα*, Matt. xii. 45; see Is. ii. 2, Mic. iv. 1; and *cf.* Acts ii. 17.

[2] See Neander, *Hist. Ch. Dogmas*, vol. i. p. 247 (Bohn's series).

[3] Ps. ii.; *cf.* Rev. ii. 27; 2 Esd. xiii. 21.

[4] Alford's note on Matt. xii. 32. For similar expressions see Titus ii. 12, Mark x. 30, Gal. i. 4, Luke xx. 35. The Hebrew equivalents were עוֹלָם הַזֶּה and עוֹלָם הַבָּא.

[5] See parable of tares, Matt. xiii., where the A. V. misses the point of the parable by translating both *αἰών* and *κόσμος* "the world." It is the harvest, the *αἰών* or age, which comes to an end, not the world.

[6] *Limbus* from an Italian word meaning *lap*.

Of these and a thousand like inquiries modern thought of course takes no notice. But there are more tremendous issues, which will never cease to engage the conscience and reason of man. The ultimate fate of the lost has created what has been called "a whirlpool of interminable controversy, roaring in endless circles over a dark and bottomless abyss."[2] "Only fragments of the dogma" are, as Neander remarks, to be found in Scripture.[3] And of these by far the greater number are poetical, and admit all the variety of interpretation possible to figurative language. The very books which are most occupied with last things found their way into the canon under protest.[4] And it has been remarked that, "in nearly every passage on which it is attempted to found the eternal misery of the lost, there is a less or greater difficulty in settling the text, or in reaching the conviction that we read as the author wrote."[5] The same uncertainty prevails all along the line of eschatological thought. In every age the popular opinion has been both more extravagant and more dogmatic than the expressed formulas of the church.[6] It is, indeed, difficult to determine what, at any one time, the mind of the church has been. Reserve was wise, but reserve has its dangers. License was given to the unguided and uncontrolled popular imagination to create and people its own heaven and hell, while poetry and art were permitted to seize on the unseen future as their own domain, and, alas, to stamp their figured expressions indelibly as literal truths on the minds of men.[7]

There are two distinct modes of treatment for these difficult subjects. In the philosophy of them we meet with the ever-recurrent antagonism between the Platonic and Aristotelian systems.[8] Thus the speculative argument on which the schoolmen and Calvinists chiefly rely in support of a theory of unending penalty for sin—that the violated majesty of an Infinite Being demands infinite pain—is founded on a sentence in Aristotle's *Ethics*;[9] while a gentler creed appears with every revival of the Platonic philosophy, which, as Neander observes, extended its spiritualizing influence to eschatology as to other doctrines of the faith.[10]

But without entering on the region of pure speculation, the New Testament itself discloses two entirely different eschatological methods. The one is moral, spiritual, idealist, employing outward forms only as symbols, viewing the future rather in regard to development of character than as a mode of existence. This is the Christian as contrasted with the Jewish method. The other follows the natural tendency of Hebrew thought. It is literal, material, sensuous. It delights in chronological arrangements of the unknown future, and topographical arrangements of the unseen world. Missing the repeated warnings of Christ, delivered both in parables and in express admonitions—warnings to prepare for a slow and gradual development of His kingdom, and to leave "the times" in His Father's keeping—this method aims in all its representations at abrupt catastrophe and at a consummation depending on startling and supernatural surprises.[11]

These distinctive tendencies appear within the New Testament most prominently—the one in the fourth gospel, the other in the Apocalypse. The Pauline theology exhibits them side by side, showing their discordance in the absence of all attempt on the part of the apostle to reconcile them. Thus in his treatment of the resurrection, in the one view it is the sudden appearing of Christ which will begin the heavenly life for all, in the other this life in Christ—begun already on earth—will attain its perfection at the death of the individual. As the moment of the second advent receded, the church's expectation necessarily transferred the object of Christian hope—the communion with Christ in the kingdom of glory—to the earlier event, death; but St. Paul retains the old terminology without endeavoring to adapt it to this change (*cf.* Phil. i. 22, 23, iii. 10, 11, with 1 Cor. xv. 52 *f.*; 1 Thess. iv. 15, etc.). The same discordance is observable in his treatment of the judgment and of the end of the world. In his use of terms and reference to times the apostle follows his Jewish training. "The day of the Lord," with all its prophetic associations as "day of judgment," is preserved; the sudden and final award of wrath or favor appears in its forensic form; and all is ended by a separation between the heirs of eternal life and the lost. But the spirit of the apostolic teaching is independent of this form. The idea that regards the development of the higher life as a constant process varying in each individual, but having its roots in the common life of the church,—that looks on to the ultimate perfection as a unity of all with the Redeemer in God, the whole universe having been gradually subdued by Christ to himself—this, which we may call the essentially Christian idea, is what we receive as the innermost feeling of the man who, from a Pharisee and a zealous upholder of the law, was called to be a chosen instrument of the gospel of the favor of God in Christ.

In the patristic period the conflict between the two rival systems is apparent in every detail. Here, as everywhere else, the opposition is marked in regard to the duration of punishment. But it rages most fiercely, perhaps, round the doctrine of the millennium. The earthly reign of Messiah was transferred from Jewish to Christian expectation. But the Christian hope could not without inconsistency take a Jewish form. Christ's kingdom of heaven refused to realize itself as a period of sensual enjoyment, and the poetic chronology of the Apocalypse was soon found to have raised difficulties of an insurmountable kind which were not diminished when a locality was sought for the promised earthly reign. If it was found at Jerusalem before the final judgment, how could the expectations connected with the second advent be fulfilled? In the Apocalypse the completion of the kingdom of God takes place in the New Jerusalem—the millennium appearing only as an interval of rest after the crisis of the conflict with Antichrist. Thus a new decisive epoch is introduced, the consummation of things having thus gradually receded from the incarnation, which was the focus of Jewish eschatology, to the second advent, and still further to the close of the millennial reign. The later interpretation, fixing the beginning of the thousand years' kingdom at the incarnation, though decidedly opposed to the Apocalypse, is a recurrence to the primitive Jewish view. In accordance with this opinion, the end of the world was very generally expected about the year 1000. Another view dated the millennium from the formal adoption of Christianity by the empire under Constantine, and caused the expectation of the end of things which was so prevalent in the 14th century.[12]

The most important of all the questions that arise in connection with eschatology relates, of course, to the teaching of our Lord. A true view of the future must be a Theodicea. It must correspond to the highest human conception of the nature and character of God. The revelation in and through Christ affords this highest conception. And yet it is in the discourses of Christ himself that men find the passages which seem to prove the doctrine most irreconcilable with the insight He has elsewhere given into the Divine heart.

---

[1] Augustine devotes much space to inquiries of this kind, *Civ. Dei*, xxii. 14, etc. The reproduction of the hair, nails, etc., is affirmed by Jerome from Matt. x. 30 See Hagenbach, *Hist. Doct.*, i. 402.

[2] Sir J. Stephen, *Essays in Eccl. Biography*, vol. i. 346.

[3] *Hist. Christ. Dogm.*, i. 247 (Bohn's series).

[4] The Apocalypse, Jude, and 2 Peter are classed by Eusebius with the doubtful or contested books (Euseb., *Hist. Eccl.*, b. iii. c. 25).

[5] White, *Life in Christ*, p. 437. For English readers the confusion is increased by the arbitrary mode in which the A. V. has dealt with many of the most important terms, such as αἰών, κρίσις, etc. See some powerful remarks on this in a volume of sermons just published by Canon Farrar, called *Eternal Hope*, p. 78, Preface, p. xxviii. *sq.*, and Excursus ii.

[6] Notice the reserve of the three great creeds—the deliberate exclusion of all pronounced opinion from the formularies of the English Church, and the comparative freedom claimed even by Roman Catholics (Newman, *Grammar of Assent*, p. 417).

[7] The part played by poetry on these subjects from the Apocalypse downward has often distressed thoughtful people. But modern poetry and the highest literature of every department are on the side of liberal and tolerant views.

[8] See Aug., *Civ. Dei*, xxi. 13.

[9] Aquinas. *Sum. Theol.*, quæst xcix., art. i. · Calvin, *Instit.*, iii. 25.

[10] The first clear note of immortality in Hebrew literature is struck in the Book of Wisdom, the work of an Alexandrian Jew. The Origenists, perhaps Scotus Erigena, and, in later times, some at least of the Cambridge Platonists, are examples of the statement above.

[11] "Abrupt Supernaturalism." Neander, *Hist. Christ. Dogm.*, i. 249.

[12] Millenarians or Chiliasts were opposed by Origen and Jerome. Augustine hesitated and changed his views about them. All were not equally gross in their conceptions. The prophetic pictures of festivity were the origin of the sensual notions. The apocalyptic literature, Sibylline oracles, etc., encouraged them. Papias (Iren., *Adv. Hær.* v. 33) puts a fantastic prediction into the mouth of Christ, on which later writers enlarged. See Aug., *Civ. Dei*, xx. 7. The specific time 1000 years did not originate with the Apocalypse. See Bleek's Introduction, and Neander, *Ch. Hist.*, ii. 496 (Bohn). Corrodi, *Kritische Geschichte des Chiliasmus*, is quoted as the classical German book on the subject. The English reader will get a full and most interesting view in Irving's *Ben Ezra*.

Now, Christ was not the first to "stamp ideas of immortality on the minds of men under the forms of heaven and hell."[1] His gospel brought life and immortality to light, but it was by illuminating obscure and completing partial truths. It is therefore most important to ascertain what forms of belief on these subjects He found existing.

Eternity of punishment is often assumed to be a truth of natural religion,—an intuitive human belief. It would be truer to say that in all races the first vague guesses at immortality include no thought of retribution at all. The continued existence was "something between being and not being."[2] Man survived only as a shadow of himself. Intellectually and morally he ended at death. Homer speaks of life and form in Hades, but says there is no mind there at all. The movement, freedom, joy of existence, ended for the Greek at death. The best that could then happen to him was to know that his body had been buried. All else was featureless, lifeless, inane,—an existence without even the excitement of the possibility of dying again. The bourne once reached, not only was there no return, but no further bourne remained to be aimed at. Thus the intense consciousness of the apparent finality of death determined the form of the earliest hopes of immortality when they began to dawn. Progress did not enter into them; there would be no discipline because nothing to exercise it on, no change of condition, for this implies power of adaptation, if not of choice.

The primitive Hebrew conception was even less tolerable than the Greek. Sheol,—translated by the LXX. Hades, and by the Authorized Version, with curious impartiality, thirty-one times "grave" and thirty-one times "hell,"[3]—was, as originally conceived, a vast subterranean tomb, with the barred and bolted gates common to Hebrew tombs, in which the ghosts (Rephaim) did not even flit about, but lay like corpses in a sepulchre. No thought of retribution was connected with this deep and gloomy under-world. It was the common receptacle of all. The distinctions there were social or national, not moral. The only approach to a retributive idea is found in the exile time, in an expression of Ezekiel's, who locates the uncircumcised heathen in the "sides of the pit," possibly the deepest and darkest part of Sheol. (See Ps. lxiii. 9, lxxxix. 19, cxliii. 3, cvii. 18; Job x. 20–22, xi. 8, iii. 14, xxx. 23; Is. vii. 11, xviii. 18; 1 Kings xi. 2; Ezek. xxxii. 23.)

This primitive idea had, by the time of Christ, developed under influences of a very different kind. In the first place, the horror with which an ancient Hebrew had contemplated death, because in Sheol he would be cut off from all communion with the covenant God, was dissipated under the truer religious feeling struggling into life in the later Psalms and the book of Job.[4] At first it had been believed that Jehovah's control did not reach to the under-world. The King of Terrors was its only king. They who had been God's sheep when alive, in Sheol had a new shepherd, Death (Ps. xlix. 14, Perowne's translation). But truer views of God's nature dissipated this horror, and pious souls who despaired of redress in this life, began to look even in Sheol for a manifestation of divine justice and a proof of divine love. At length was grasped the hope of a deliverance from the prison-house of the dead, and the doctrine of the resurrection crowned his hope, and gave a definite shape to the eschatology of the Jews.[5]

The release from the under-world which the Jew contemplated in a bodily resurrection was found by Aryan thought in a metempsychosis. According to Josephus (*Bell. Jud.* ii. 8, 14), this was also a doctrine of the Pharisees and the Essenes, and the notion of pre-existence has even been traced in the New Testament.[6] The idea of retribution has now entered into eschatology, and there is a curious analogy between the Hebrew conception and Plato's. The Greek philosopher leaves incurables to suffer in the lower regions (*Rep.*, x. 615, *cf. Phædo*, 114), when other men have choice of new lives.[7] So the Hebrews believed that the heathen and unjust would remain in the death-sleep of Sheol, while faithful Israel received back the soul in the resurrection (2 Macc. vii. 14, *cf.* Jos., *Ant.*, xliv. 1, 3). In different forms this thought reappears in Christian eschatology. Some find it in St. Paul. It was the origin of the belief in a two-fold resurrection: the unjust, not being worthy to participate when the saints awake at their Lord's second coming, remain below till the final judgment.

But in the post-exile days—that veritable middle age of Israel—other influences appeared. Intolerable wrongs drove men to seek solace for themselves in visions of paradise, vengeance on their foes in visions of hell. Now appear the divisions of Sheol into receptacles for the good and bad. Their origin is seen in the apocalyptic book of Enoch. In chap. xxii. of that remarkable book, which, in the permanence of its influence as well as its form, resembles the *Inferno* of Dante,[8] the seer is shown the "delightful places" where the souls of the good will be collected till judgment, and the "separations" existing between the just and unjust, "made by chasm, by water, by light above it."[9] And here first is express mention of "the castigation and the torment of those who eternally execrate and whose souls are punished and bound there for ever."[10]

Analogies have been found between the Greek Tartarus[11] and the Hebrew hell, and the influence of the Western mythology traced in the latter; but in order to supply symbolism of torment of surpassing horror, no foreign influence was necessary. Gehenna (*i.e.*, the valley of Hinnom or the sons of Hinnom) and its ghastly associations were ready to supply images terrible beyond any that the mind of heathen poet or philosopher had conceived. Already known as the perpetual abode of corruption and fire, "the place where lie the corpses of those who have transgressed against Jehovah—and their worm shall not die, neither shall their fire be quenched," it had become the apt symbol of utter moral depravity and ruin. But it was the unknown author of the book of Enoch who first saw it as "the accursed of the accursed for ever," who first placed in the dark ravine one of the mouths of hell, and thus from an emblem of the moral ruin attending sin, made it the actual place of punishment for sinners.[12]

Henceforth Gehenna—hell—becomes known as a part of Hades, or Sheol. There is yet another place of torment reserved for the final reception of fallen angels and wicked men. It is the lake of fire and brimstone of the Apocalypse. Its origin also appears in Enoch, though the descriptions are too confused to allow of certain identification of the locality. It is situated to the west near the "mountain of metals," and has by some been referred to the solfatara in South Italy.[13] But more probably the region is that of the Dead Sea, to which Jude refers by name in his account of the fate awaiting the fallen angels.[14] When in the Apocalypse the New Jerusalem is about to descend from heaven, Hell[15] itself with Death is cast into this sulphurous lake—not only symbolizing the final disappearance of all evil, but also the removal as far as possible from the heavenly city of all the dread associations of the dark valley of Hinnom.

On the other side of Hades was placed Paradise—a term whose origin is self-evident. Apocalyptic literature loved to imagine a restored Eden, and fill it with all the delights of sense—streams of milk and honey, twelve trees laden with divers fruits, mighty mountains whereon grow lilies and roses (2 Esdras ii. 19). Prophetical language supplied other symbols of joy—especially the happy banquet with the forefathers of the race (Luke xiii. 29, xvi. 22, *cf.* Isa. xxv. 6, etc.). In later times long controversies have turned on those localities; the "minds at once logical and sensuous ask questions, and the answers are wildly conjectural;" and no one can yet decide whether paradise, Abraham's bosom, and the third heaven are identical or different places.[1]

[2] Locke, *The Reasonableness of Christianity*.

[3] Neither translation is altogether happy. It was more than "grave," and though etymologically equivalent to "hell" (the hollow), it did not gather any of the associations of hell till after the close of the canon.

[4] Is. xxxviii. 18; Ps. cxv. 17, vi. 56, xxx. 9. See on the development of ideas of immortality in the Old Testament a treatise, *Ueber die Alttestamentlichen Vorstellungen vom Zustande nach dem Tode*, by Bernhard Stade, Leipsic, 1877.

[5] Ps. xvi. 10, lxxiii. 23–26, cxxxix. 7–10; Job xix. 25. The symbolic use by Ezekiel of a resuscitation to express a national deliverance shows the line along which this doctrine was reached.

[6] See Glanville's *Lux Orientalis*, and Dr. H. More's *Divine Dialogues* on John ix. 2.

[7] Egypt appears to have been the common source of these ideas. See Herod. ii. 123. Their influence on the views of Origen is well known.

[8] *Cf.* Stanley, *Jewish Church*, iii. 372.

[9] *Cf.* Luke xvi.

[10] Lawrence's Translation. The expression in Daniel xii. 2, "Some to shame and everlasting contempt," is much less explicit.

[11] The participle ταρταρώσας = having hurled into Tartarus, occurs in 2 Pet. ii. 4. This is the only instance of the use of the word either in the LXX. or N. T. It should be remembered that the Greek Tartarus was properly the prison-house of defeated gods or demi-gods, and that its employment in the place cited as the dungeon for fallen angels is in strict analogy.

[12] The precise topographical description of Gehenna in Enoch, which the Palestine Exploration Survey has confirmed in detail, is another likeness to Dante's mapped and measured hell. See Stanley, *Jewish Ch.*, iii. 373, note, and *Jerusalem Recovered*, p. 307.

[13] In Enoch, however, this "flaming womb of hell" is apparently the temporary place, Gehenna being the final abode of woe (Stanley, p. 374).

[14] Jude 6, 7. See Renan, *L'Antichrist*, p. 333, note.

[15] The word γέεννα however does not appear in the Apocalypse; Hades has quite taken its place (*cf.* Luke xvi. 23).

Further extravagances may be found in the Rabbinical writings and in the many apocalypses which the early church produced. The limboes of patristic speculation have their antitypes in the chambers (*promptuari*) out of which come to Esdras the querulous voices of the dead.[2] In the Talmudic representations of hell there is a foreshadowing of the Roman purgatory.[3] But we cannot pursue Jewish eschatology into all its fanciful recesses. Enough has been said to show that when our Lord came he found the doctrines of last things presented in forms already fixed, and the terms Gehenna, Paradise, etc., in familiar and even proverbial use (Matt. xxiii. 15, *cf.* James iii. 6).

The popular views of a future state regard the use Jesus made of current terms as a sanction of their literal meaning. But from the very earliest Christian times another interpretation has been given. It has been understood that Christ treated popular religious terms as only the symbols of a false creed can be effectually treated. He rescued them for the service of the new and true. "He took from their future and remote, in order to give them a present and immediate, force and aspect." He employed the familiar images of heaven and hell to impress on men's consciences the supreme bliss of righteousness and the awful misery of sin.[4] If His words have been misapprehended and misrepresented in this particular, so were they, even by the first disciples, in others (John xi. 13; Mark viii. 16, etc.). He taught on the principle of His well-known saying, "He that hath ears to hear, let him hear."[5]

Special instances would take us to too great a length. Christ's treatment of the resurrection, both with sceptics and believers (Matt. xxii. 30-32; John xi. 25), was such as to dislodge His hearers' thoughts from the accidents (so to speak) of the great change, and fix them on its moral and spiritual aspects. The same intention appears also in His allusion to the judgment (John v. 25); while in the one unmistakable reference to the future heaven, He fastens the hope of His followers entirely on the thought of abiding communion with Himself (John xiv. 1-3.)

There are still certain features of eschatological doctrine which require notice. The notion of an Intermediate State was generally prevalent during the first three centuries. It was exactly analogous to the Jewish notion of a divided under-world. The souls of the pious, says Justin (*D. c. Tryph.*, 5), take up their abode in a better, those of the wicked in a worse place. Tertullian, however, believed that the martyrs went direct to the bliss of heaven—a view probably founded on Rev. vii. 14, 15. The doctrine changed its shape many times. It produced an Arabian heresy combated by Origin, that both soul and body fall into a death-sleep, from which they will not awake to the last day. Revived at a later time, under the name Psychopannychy, it was made the subject of a treatise by Calvin. But the existence of an intermediate state remains a dogma of the Eastern Church to this day. In the Western the doctrine of Purgatory gradually absorbed it.

The idea of a purifying fire seems to have grown originally out of the belief in the general conflagration of the world. This belief, which so much occupies the Sibylline books, came perhaps from the Stoic philosophy.[6] It was supported by Deut. xxxii. 22, and though it finds no place in the Apocalypse, had penetrated religious thought before the composition of the second epistle of Peter (2 Pet. iii. 7-12). The early fathers agree in ascribing to this fire a purgative virtue, but with every variety of opinion as to the mode of its operation. Augustine first transferred it to Hades and the intermediate state, thus laying the foundation for the view of purgatory which Gregory the Great formulated into a dogma. Distinction must always be made between the early purifying flames, through which good and bad alike were destined to pass, and the Roman purgatory, in which only those destined at last for heaven worked out the residue of the temporal penalty for sin.[7]

Reformed eschatology differs from that of the primitive church in the absence of the intermediate state, from that of Rome in the rejection of purgatory. Both these forms of belief are felt to have mitigated in some degree the doctrine of an endless hell, which in Protestantism is brought more prominently into the foreground, the final doom being fixed not now at the general judgment, but at death, at which, without any authority from Scripture, the popular creed supposes the sinner's fate to be unalterably determined.

Many attempts in different quarters have been made to revive the milder creeds of the early church.[8] A touching account of them may be read in Mr. Maurice's famous essay. His own struggle to regain for the adjective *αἰώνιος* its ethical sense is well known. Perhaps he took too little account of the element of duration undoubtedly existing in it. The two senses pass imperceptibly into one another, but the scriptural use, when not distinctly ethical, gives it the sense of indefinite not of endless duration.[9] But Mr. Maurice vindicated, at least for English clergymen, a perfect freedom on this subject; and though in his own case the claim was not allowed, his opinion was confirmed by the formal decision in the "Essays and Reviews" case.

The result of this is apparent now throughout the thinking part of Christendom; the subject of eschatology, in connection with the wider subject of immortality, is exercising profound attention. Philosophy and science are equally concerned in it with religion.[10] Theologians recognizing this are in many different ways trying to reconcile the voice of Scripture with the voices of science and philosophy.

Two prominent attempts perhaps claim notice. The advocates of Conditional Immortality or Annihilation maintain, from the letter of Scripture, destruction and not endless suffering to be the destiny of the lost. They take advantage of the doubt existing as to St. Paul's doctrine of the termination of the world in unity—whether by unbelievers being completely annihilated, or by their being all finally converted.[11] The view that immortality is not inherent in fallen human nature, but is the gift of God in Christ, has had many supporters, and in this part of their system, the advocates of annihilation justly claim the authority of many great names. But the details of their eschatology are somewhat confused and conflicting.[12] They claim, however, with some doubt, Justin,

[1] See art. "Paradise," in Smith's *Bib. Dict.*

[2] 2 Esd. iv. 35; see Renan, *Les Evangiles*, p. 357, note.

[3] If we may determine the Jewish view of Gehenna in the time of our Lord from the opinion of modern rabbis and their exegesis of the Talmud, endless torment by no means formed part of the doctrine: "it meant *not* a material and everlasting fire, but an intermediate, a remedial, a metaphorical, a terminable retribution."—Farrar, *Eternal Hope*, p. 81, and Excursus v.

[4] This view is very generally adopted with regard to the "worm" of Gehenna, which is interpreted to mean the gnawing of an evil conscience. Unfortunately the fashion set by Augustine of choosing what terms shall be literal and what metaphorical has prevailed. See Aug., *Civ. Dei*, xxi. 9, "Let each one make his own choice, either assigning the fire to the body and the worm to the soul,—the one figuratively, the other really, or assigning both really to the body."

[5] Still a careful regard to audience is traceable in his use of apocalyptic language about His second coming; it is to Jews only,—the twelve, or the High Priest, or the Sanhedrim, or Nathanael—the "Israelite indeed,"—that he speaks of cleft heavens, cloud chariots, and attendant troops of angels. With the Roman governor he avoids Jewish metaphors.

[6] Justin, *Apol.* i. 44, etc. See Renan, *Les Évangiles*, p. 170, note, where the Stoic authorities are given.

[7] Authorities for the history of Purgatory will be found in Hagenbach and Neander.

[8] Modern divines (at least in the English Church) have tried to revive the ancient doctrines.

[9] Mr. White says that of the 90 subjects to which it or its cognates are applied 70 are of a temporary nature. See on this subject Farrar, *Eternal Hope*, p. 79, and Excursus iii. He shows beyond dispute, what scores of writers (see *e.g.*, Burnett, *De statu mortuorum*) had shown before, that, though applied to some things which are *endless*, *αἰώνιος* does not in itself mean *endless*.

[10] See *Unseen Universe*, pp. 263 *sq.*

[11] See Pfleiderer, *Pauline Theol.*, c. vii., and *cf.* Baur, *Life and Works of Paul*, iii. 6, "Whatever he thought on the question, it must be perfectly clear that if death is to be robbed of his last sting there can be no eternal punishment."

[12] For instance, as to the nature and duration of the retributive punishment which the wicked will undergo before destruction, the time of the resurrection, and the principle on which those to be annihilated will be doomed, etc.

Irenæus, Arnobius, and others among the fathers, and Dodwell, Locke, Watts, Whately, etc., among later writers.[1] The best account of the doctrine is contained in a remarkable volume by the Rev. E. White called *Life in Christ*.

The Universalists or Origenists maintain, in the language of Acts iii. 21, a hope of the "restitution of all things." The hope is grounded not on the literal assertion of any one text,—though as many are quoted in its favor as in that of any other theory of the future,—but on the divine character and purpose as revealed in Christ, and the implied failure of the redemptive work of the Saviour unless all for whom He died ultimately partake of salvation. Between this and the Augustinian system, which the great doctor candidly confesses dooms the vast majority of men to endless perdition, there are of course many gradations of opinion. Possibly Universalists are apt to quote in their favor all who in any degree show themselves, to use Augustine's word, more merciful. Certainly a long list of illustrious names claim rank among them. Origen, of course, heads it, though earlier fathers—Athenagoras, for instance—are sometimes called in as witnesses of the milder creed. The fate of those who had died before Christ, and of the heathen, began at an early time to exercise the conscience of Christians. The descent of Christ into hell was by many believed to have had for its object the deliverance of souls from thence.[2] The Pastor of Hermas is understood to join the elect with Christ in his benign ministry. Clement of Alexandria, Theophilus of Antioch, Gregory of Nazianzen, and Gregory of Nyssa, Diodorus of Tarsus, Didymus of Alexandria, Theodore of Mopsuestia, even Jerome, Ambrose, Scotus Erigena; and in later times on the Continent, Bengel, Neander, Oberlin, Hahn, Tholuck, and Martensen; in England, among the Puritans, Jeremiah White and Peter Story; in the English Church, Jeremy Taylor, Dr. H. More, Thomas Burnet,[3] Richard Clark, Bishop Edmund Law, Bishop Rust, William Law, and George Stonehouse; and many in more recent times still,[4]—are all to be ranked among believers in a general restoration. A work by Mr. Andrew Jukes, *The Restitution of all Things*, states the doctrine, though with some peculiarity of scriptural interpretation, very forcibly. Perhaps the reader of that work may think that it shifts the burden of proof from those who resist to those who maintain the doctrine of an endless hell.[5] (A. S. A.)

ESCHEAT (*escœta*), in English law, is the reversion of lands to the next lord on the failure of heirs of the tenant. "When the tenant of an estate in fee simple dies without having alienated his estate in his lifetime or by his will, and without leaving any heirs either lineal or collateral, the lands in which he held his estate escheat, as it is called, to the lord of whom he held them" (Williams on the *Law of Real Property*). This rule is explained by the conception of a freehold estate as an interest in lands held by the freeholder from some lord, the king being lord paramount. (See Estate.) The granter retains an interest in the land similar to that of the donor of an estate for life, to whom the land reverts after the life estate is ended. As there are now few freehold estates traceable to any mesne or intermediate lord, escheats, when they do occur, fall to the king as lord paramount. Besides escheat for defect of heirs, there was formerly also escheat *propter delictum tenentis*, or by the corruption of the blood of the tenant through attainder consequent on conviction and sentence for treason or felony. The blood of the tenant becoming corrupt by attainder was decreed no longer inheritable, and the effect was the same as if the tenant had died without heirs. The land, therefore, escheated to the next heir, subject to the superior right of the crown to the forfeiture of the lands,—in the case of treason for ever, in the case of felony for a year and a day. All this has been abolished by the 33 and 34 Vict. c. 23 (the Felony Act, 1870), which provides for the appointment of an administrator to the property of the convict. Escheat is also an incident of copyhold tenure. Trust estates, by a recent Act, are protected from escheat.

ESCHENBACH, Wolfram von. See Wolfram.

ESCHENBURG, Johann Joachim (1743-1820), a German littérateur, was born at Hamburg, 7th December, 1743. After receiving his early education in his native town, he studied at Leipsic and Göttingen. In 1767 he was brought by the court-preacher Jerusalem to Brunswick, and through his influence he became a professor in the Collegium Carolinum. He was also made an aulic councillor, and senior of the Syriac college, and ultimately received the office of privy councillor of justice. He is best known by his German translations of English works. He published a series of German translations of the principal English writers on æsthetics, such as Brown, Burney, Priestley, and Hurd; and Germany owes also to him the first complete translation of Shakespeare's plays, which, though it is deficient in poetical merits, and somewhat too free, is still valuable on account of its general correctness. He died on the 27th April, 1820.

Besides editing, with memoirs, an edition of the later German poets, he is the author of *Handbuch der Classichen Literatur* (1783); *Entwurf einer Theorie und Literatur der schönen Wissenschaften* (1783); *Beispielsammlung zur Theorie und Literatur der schönen Wissenschaften* (8 vols., 1788–95); *Lehrbuch der Wissenschaftskunde*(1792); and *Denkmäler altdeutscher Dichtkunst*(1799). Most of these works have passed through several editions.

ESCHENMAYER, Karl Adolf August von (1770-1852), a German philosopher and physicist, was born at Nuremberg 4th January, 1770. After receiving his early education at the Caroline academy of Stuttgart, he entered the university of Tübingen, where he received the degree of doctor of medicine. He practised for some time as a physician at Sulz and then at Kirchheim, and in 1811 he was chosen extraordinary professor of philosophy and medicine at Tübingen. In 1818 he became ordinary professor of practical philosophy, but in 1836 he resigned his professorship, and took up his residence at Kirchheim, where, till the close of his life, he devoted his whole attention to philosophical studies. He died on the 13th November, 1852. The philosophy of Eschenmayer is grounded primarily on the Kantian metaphysics, and in many particulars his views are identical with those of Schelling, but he differed from him in regard to the knowledge of the absolute. He believed that in order to complete the arc of truth philosophy must be supplemented by what he called "non-philosophy," a kind of mystical illumination by which was obtained a belief in God that could not be reached by mere intellectual effort. Thus beyond that system of truth which, according to the three ideas of the true, the beautiful, and the good, he divided into physics, æsthetics, and ethics, he recognized a transcendental revelation given in the idea of the holy. He carried this strong tendency to mysticism into his physical researches, and was led by it to take a deep interest in the phenomena of animal magnetism. He ultimately became a devout believer in demoniacal and spiritual possession; and his later writings are all strongly impregnated with this lower supernaturalism.

His principal works are—*Die Philosophie in ihrem Uebergange zur Nichtphilosophie*, 1803; *Versuch die scheinbare Magie des thierischen Magnetismus aus physiol. und psychischen Gesetzen zu erklären*, 1816; *System der Moralphilosophie*, 1818; *Psychologie in drei Theilen, als empirische, reine, angewandte*, 1822; *Religionsphilosophie*, 3 vols., 1818–24; *Die Hegel'sche Religionsphilosophie verglichen mit dem Christl. Princip.*, 1834; *Der Ischariotismus unserer Tage*, 1835 (directed against Strauss's *Life of Jesus*); *Conflict zwischen Himmel und Hölle, an dem Dämon eines besessenen Mädchens beobachtet*, 1837; *Grundriss der Naturphilosophie*, 1832; *Grundzüge der Christl. Philosophie*, 1840; and *Betrachtungen über der physischen Weltbau*, 1852.

ESCHSCHOLTZ, Johann Friedrich, a German traveller and naturalist, born November 12, 1793, at Dorpat, where he died May 12, 1831. He was naturalist and physician to Kotzebue's exploring expedition during 1815–18. On his return, he was appointed professor of medicine, and manager of the zoological museum of the university at Dorpat, and in 1823–26 he accompanied Kotzebue on his second voyage of discovery. Among Eschscholtz's publications are the *System der Akalephen*, Berlin, 1829, and the *Zoologischer Atlas*. The genus of plants *Eschscholtzia* was named by Chamisso in honor of the naturalist. For a figure of the first species described, *E. californica*, see E, plate ii. in vol. iv. of this work.

---

[1] The language of the fathers, who adopted Scripture as they found it, is frequently self-contradictory. "In the earliest of them, Justin Martyr and Irenæus, are some well-known passages which seem clearly to imply either the ultimate redemption or the total destruction of sinners."—Farrar, *Eternal Hope*, p. 155.

[2] This was founded on 1 Pet. iii. 19. See Pearson *On the Creed*, and Burnet on Art. 3. Justin and Irenæus especially had this view, but it was also general among the fathers.

[3] See his book *De Statu Mortuorum*.

[5] See for full account of opinions Farrar, *Eternal Hope*, pp. 155 *sq.*

ESCHWEGE, the head town of a circle in the district of Cassel, province of Hesse-Nassau, Prussia, is situated on the Werra, and on the Bebra-Friedland railway, about 28 miles south-east of Cassel. It consists of the old town on the left bank of the Werra, the new town on the right bank, and Brückenhausen on a small island connected with the old and new town by bridges. It is a thriving manufacturing town, its chief industries being leather-making, yarn-spinning, cotton- and linen-weaving, the manufacture of liquors and oil, and glue- and soap-boiling. It has two ancient buildings, the Nicholas tower, built in 1455, and the old castle. The population of Eschwege in 1875 was 7724.

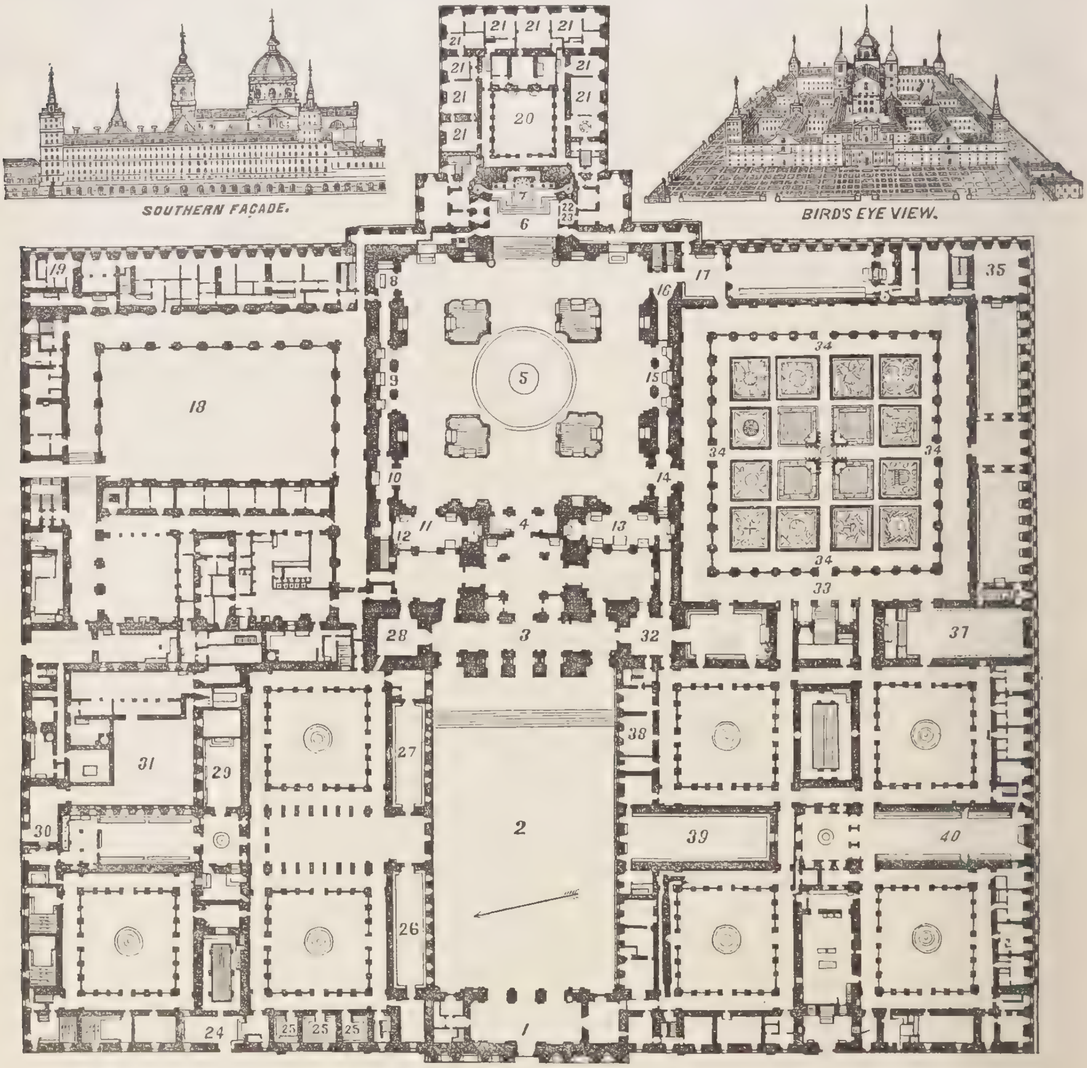
ESCHWEILER, a town of Rhenish Prussia, in the government district of Aix-la-chapelle, is situated on the Inde, and on the Berg-Mark railway, about 8 miles E.N.E. from Aix-la-chapelle. It possesses three large iron-rolling mills, and among its other industries are the manufacture of iron and tin wares, muslins, needles, and wire. In the neighborhood are some very valuable coal mines. The population in 1875 was 15,540.

ESCOBAR Y MENDOZA, Antonio (1589–1669), a Spanish casuist, was a descendant of the illustrious house of Mendoza, and was born at Valladolid in 1589. He was educated by the Jesuits, and at the age of fifteen took the habit of that order. He soon became a famous preacher, and his facility was so great that for 50 years he preached daily, and sometimes twice a day. Notwithstanding his constant oratorical efforts, he was a voluminous writer, and published altogether forty vols. in folio. His first literary efforts were Latin verses in praise of St. Ignatius Loyola and the Virgin Mary; but he is best known as a writer on casuistry. His principal works are—*Summula Casuum Conscientiæ*, several Scripture commentaries, *Liber Theologiæ moralis*, and *Universæ Theologiæ moralis Problemata*. The first mentioned of these was severely criticised by Pascal in the fifth and sixth of his *Provincial Letters*, as tending to inculcate a loose system of morality. It contains the famous maxim that purity of intention may be a justification of actions which are contrary to the moral code and to human laws; and its general tendency is to find excuses for the majority of human frailties. His doctrines were disapproved of by many Catholics, and were mildly condemned by Rome. They were also ridiculed in witty verses by Molière, Boileau, and La Fontaine, and gradually the name Escobar came to be used in France as a synonym for a person who is adroit in making the rules of morality harmonize with his own interests. Notwithstanding the apparent looseness of his moral teaching, Escobar is said to have been simple in his habits, a strict observer of the rules of his order, and unweariedly zealous in his efforts to reform the lives of those with whom he had to deal. He died 4th July, 1669.

ESCORIAL, or, as the name is not unfrequently given, Escurial, one of the most remarkable buildings in Europe, comprising at once a convent, a church, a palace, and a mausoleum. It is situated on the south-eastern versant of the Sierra de Guadarrama, on the borders of New Castile, about 27 miles N.W. of Madrid, and immediately to the north of the railway between Madrid and Avila. Its latitude is 40° 35′ N., its longitude 4° 1′ W., and its height above the sea 3500 feet. The surrounding country is a sterile and gloomy wilderness exposed to the cold and blighting blasts of the Sierra. According to the usual tradition, which there seems no sufficient reason to reject, the Escorial owes its existence to a vow made by Philip II. of Spain shortly after the battle of St. Quentin, in which his forces succeeded in routing the army of France. The day of the victory, August 10, 1557, was sacred to St. Laurence, and accordingly the building was dedicated to that saint and received the title of *El real Monasterio de San Lorenzo del Escorial*. The last distinctive epithet was derived from the little hamlet in the vicinity which furnished shelter, not only to the workmen, but to the monks of St. Jerome who were afterwards to be in possession of the monastery; and the hamlet itself is generally but perhaps erroneously supposed to be indebted for its name to the *scoriæ* or dross of certain old iron mines. The preparation of the plans and the superintendence of the work were entrusted by the king to Juan Bautista de Toledo, a Spanish architect who had received most of his professional education in Italy. The first stone was laid in April, 1563; and under the king's personal inspection the work rapidly advanced. Abundant supplies of berroqueña, a granite-like stone, were obtained in the neighborhood, and for rarer materials the resources of both the Old and the New World were put under contribution. The death of Toledo in 1567 threatened a fatal blow at the satisfactory completion of the enterprise, but a worthy successor was found in Juan Herrera, Toledo's favorite pupil, who adhered in the main to his master's designs. On September 13, 1584, the last stone of the masonry was laid, and the works were brought to a termination in 1593. Each successive occupant of the Spanish throne has done something, however slight, to the restoration or adornment of Philip's convent-palace, and Ferdinand did so much in this way that he has been called a second founder. In all its principal features, however, the Escorial remains what it was made by the genius of Toledo and Herrera working out the grand, if abnormal, desires of their dark-souled master.

The ground plan of the building is said to occupy an area of 396,782 square feet, and the total area of all the stories would form a causeway one metre in breadth and 95 miles in length. There are seven towers, fifteen gateways, and, according to Los Santos, no fewer than 12,000 windows and doors. The general arrangement is shown by the plan on page 478. Entering by the main entrance the visitor finds himself in an atrium, called the Court of the Kings (*Patio de los Reyes*) from the statues of the kings of Judah, by Juan Bautista Monegro, which adorn the façade of the church. The sides of the atrium are unfortunately occupied by plain ungainly buildings five stories in height, awkwardly accommodating themselves to the upward slope of the ground. Of the grandeur of the church itself, however, there can be no question: it is the finest portion of the whole Escorial, and, according to Fergusson, deserves to rank as one of the great Renaissance churches of Europe. It is about 340 feet from east to west by 200 from north to south, and thus occupies an area of about 70,000 square feet. The dome is 60 feet in diameter, and its height at the centre is about 320 feet. In glaring contrast to the bold and simple forms of the architecture, which belongs to the Doric style, were the bronze and marbles and pictures of the high altar, the masterpiece of the Milanese Giacomo Trezzo, almost ruined by the French. Directly under the altar is situated the pantheon or royal mausoleum, a richly decorated octagonal chamber with upwards of twenty niches, occupied by black marble *urnas* or sarcophagi, kept sacred for the dust of kings or mothers of kings. There are the remains of Charles V., of Philip II., and of all their successors on the Spanish throne down to Ferdinand VII., with the exception of Philip V. and Ferdinand VI. Several of the sarcophagi are still empty. For the other members of the royal family there is a separate vault, known as the *Panteon de los Infantes*, or more familiarly by the dreadfully suggestive name of *El Pudridero*. The most interesting room in the palace is Philip II.'s cell, from which through an opening in the wall he could see the celebration of mass while too ill to leave his bed. The library, situated above the principal portico, was at one time one of the richest in Europe, comprising the king's own collection, the extensive bequest of Diego de Mendoza, Philip's ambassador to Rome, the spoils of the emperor of Morocco, Muley Zidan, and various contributions from convents, churches, and cities. It suffered greatly in the fire of 1671, and has since been impoverished by plunder and neglect. Among its curiosities still extant are an ancient Koran, a Virgil of the 10th century, an Apocalypse of the 14th, *El libro de los juegos de Ajedrez*, or "Book of the Games of Chess," by Alphonso the Wise, and the original Alcalá ordinance. Of the Arabic manuscripts which it contained in the 17th century a catalogue was given in Hottinger's *Promptuarium sive Bibliotheca Orientalis*, and another in the 18th, in Casiri's *Bibliotheca Arabico-Hispanica*, 2 vols., Madrid, 1760–70. Of the artistic treasures with which the Escorial was gradually enriched, it is sufficient to mention the frescoes of Peregrin Tibaldi, Carbajal, Bartolome Carducho, and Lucas Jordan, and the pictures of Claudio Coello, Titian, Tintoretto, Van der Weide, and Velasquez. Many of those that are movable have been transferred to Madrid, and many others have perished by fire or sack. The conflagration of 1671, already mentioned, raged for fifteen days, and only the church, a part of the palace, and two towers escaped uninjured. In 1808 the whole building was exposed to the ravages of the French soldiers under Houssaye. On the night of the 1st of October, 1872, the college and seminary, a part of the palace, and the upper library were devastated by fire; but the damage occasioned by this has in great measure been repaired.

The reader will find a remarkable description of the emotional influence of the Escorial in Quinet's *Vacances en Espagne;* and for historical and architectural details he may consult the following works:—Fray Juan de San Geronimo, *Memorias sobre la Fundacion del Escorial y su Fabrica*, in the Coleccion de Documentos ineditos para la Historia de España, vol. vii.; Herrera, *Sumario y Breve Declaracion de los Diseños y Estampas de la Fab. de S. Lorenzo del Escorial*, Madrid, 1589; José de Siguenza, *Historia de la Orden de San Geronymo*, Madrid, 1590, etc.; Cabrera, *Felipe Segundo*, 1619; James Wadsworth, *Further Observations of the English Spanish Pilgrime*, London, 1629, 1630; Ilario Mazzorali de Cremona, *Le reali grandezze del Escuriale*, Bologna, 1648; De los Santos, *Descripcion del real monasterio*, etc., Madrid, 1657; Andres Ximenes, *Descripcion*, etc., Madrid, 1764; Quevedo, *Historia del Real Monasterio*, etc., Madrid, 1849; Rotondo, *Hist. artistica, etc., del monasterio de San Lorenzo*, Madrid, 1856–1861; Prescott, *Life of Philip II.;* Mrs. Pitt Byrne, *Cosas de España*, 1866; Fergusson, *Hist. of the Modern Styles of Architecture*, 1873.



Views and Plan of the Escorial.[1]

CHURCH.
1. Principal entrance and portico.
2. Court of the kings (*Patio de los reyes*).
3. Vestibule of the church.
4. Choir of the seminarists.
5. Centre of the church and projection of the dome.
6. Greater chapel.
7. High altar.
8. Chapel of St. John.
9. Chapel of St. Michael.

34. Court of the evangelists.
35. Prior's cell.
36. Archives.
37. Old church.
38. Visitors' hall.
39. Manuscript library.
40. Convent refectory.

ESDRAS, BOOKS OF. The books called Esdras third and fourth in the sixth Article of the Church of England (1563) have been more commonly known to English readers since the publication of the Geneva Bible (1560) as Esdras first and second. In the earliest Protestant edition of the German Bible (where for the first time the apocryphal books were sharply separated from the canonical) these two books of Esdras or Ezra stood first in the former class (1530). Though neither of them was included by Luther in his version of the Apocrypha published in 1534, they both reappeared in Coverdale's English Bible (1535) at the head of the list, and this position they have maintained in all subsequent English translations. On the other hand, they do not occur in the Complutensian polyglot (1514–17); they were wholly excluded from the canon by the Council of Trent (1546); nor did they appear in the Sixtine edition of the Vulgate (1590). They were printed, however, in the Clementine edition of 1592, along with the Prayer of Manasseh, though merely as an appendix, and with a preface to explain that they were permitted thus to appear only because they had been occasionally referred to by the fathers, and had found their way into some Latin Bibles both written and printed. Though associated thus closely in the vicissitudes of their later history, they have no such intimate relationship to one another as is suggested by their names. They differ widely in age, origin, theological interest, literary and historical importance, and must accordingly be treated as entirely separate works.

---

[1] Reduced from a large plan of the Escorial in the British Museum, "*Monasterio del Escorial*," published at Madrid in 1876.

1 Esdras, the *Liber tertius Esdræ* of the Vulgate and the thirty-nine Articles, is entitled in the Codex Vaticanus and in modern editions of the LXX. Ἔσδρας α′, but in the Codex Alexandrinus simply ὁ ἱερεύς. With the exception of chaps. iii., iv., and v. 1–6, it is a mere compilation from the canonical work Chronicles-Ezra-Nehemiah. Chap. i., which gives an account of the celebration of the passover under Josiah, and then continues the history to the destruction of Jerusalem in 588 B.C., follows verse by verse the narrative of 2 Ch. xxxv. 1–xxxvi. 21. There are, indeed, numerous verbal discrepancies, which show that the writer had before him a Hebrew text somewhat different from that which we now possess, or else that he made use of a Greek version other than the Alexandrian. Sometimes, too, he may seem to have deliberately abridged or expanded the text that lay before him; but the fact that on the whole he depended on the Chronicler must be abundantly manifest to any reader, and needs not be demonstrated here. The whole of the canonical book of Ezra is next incorporated, but with an interpolation and a dislocation. Chap. ii. 1–14, telling of the edict of Cyrus and the return of the Jews under "Samanassar" or "Sanabassar," closely follows Ezra i. In like manner, chap. ii. 15–25, telling how the works at Jerusalem were interrupted by the interdict of Artaxerxes, though introduced at an earlier stage in the narrative, is entirely derived from Ezra iv. 7–24. Chap. iii. 1–v. 6, relating how the young Zerubbabel gained the ear of Darius, and successfully reminded him of a forgotten vow to rebuild Jerusalem and the temple, and to restore the holy vessels and permit the return of the citizens to their places, is, as has already been indicated, either an original contribution or one derived from some source which is no longer accessible to us. Chap. v. 7–70, containing the list of those who returned with Zerubbabel under "Darius," with an account of the progress of the temple under "Cyrus," and of the subsequent interruption "for the space of two years," until the reign of "Darius," is derived from Ezra ii. 1–iv. 5. Chaps. vi. and vii., corresponding to Ezra v. and vi., relate how the work was resumed under Darius, and completed in the sixth year of his reign. Chap. viii. 1–ix. 36 repeats the narrative of Ezra vii.–x., and chap. ix. 37–55 that of Neh. vii. 73–viii. 13.

The abruptness which characterizes the book as we now have it, both in its beginning and at its close, suggests the idea that possibly it may be merely a fragment of some larger compilation to which reference is perhaps made in 2 Macc. ii. 13. In its present form it has little to distinguish it as a composition from the work of the Chronicler, of which it is virtually an incomplete abridgment. The special object which the compiler may have had in view is indeed not easily conjectured. Some writers think they can discover a two-fold purpose—to give prominence to the new story about Zerubbabel, and to remove chronological difficulties which are raised by the canonical book of Ezra. If the latter was indeed part of his aim, he has been singularly unsuccessful. Far from obviating any of the difficulty caused by the Chronicler's having apparently introduced Artaxerxes Longimanus and Xerxes between Cyrus and Darius Hystaspis, he has landed himself in new and glaring inconsistencies (comp. *e.g.*, ii. 10, 14, with iv. 44). A more likely hypothesis is that his design was to give to the public something more readable than the bald and literal Alexandrian translation. Critics are not unanimous upon the question whether he took his work directly from the Hebrew or from the present LXX. version. The majority are in favor or the former view; but Keil has the influential support of Schürer (in Herzog's *Encyklopädie*, i. 497, 1877) in the latter opinion. It is uncertain where he wrote. Egypt and Palestine have both been suggested, but without adequate data for a definite conclusion. Whoever he was he had a good command of Greek, nor was he ignorant of Hebrew. As for the date of the work, all we know is that it was already in existence and in repute in the time of Josephus. That historian has unfortunately followed its order of events in preference to that of the canonical Chronicler, and so has brought his narrative into inextricable confusion in all that relates to the Persian period.

Unmistakable references to the work as authoritative are to be met with in Clement of Alexandria, in Cyprian, in Athanasius, and in Augustine (*De. Civ. Dei*, xviii. 36). Jerome, on the other hand, in his preface to Ezra and Nehemiah (which is to be found in all modern editions of the Vulgate), has condemned both books of Esdras as "somnia" and "procul abjicienda." It does not occur in any list either of canonical or of "ecclesiastical" writings.[1] Nor does its place in the Alexandrian canon seem to have been altogether undisputed. For it does not occur in *all* Latin Bibles presumably derived from the LXX.; and towards the beginning of the 16th century it was believed not to exist at all in Greek, so rare had it become.

2 Esdras, the *liber quartus Esdræ* of the Vulgate[2] (Ezra, Nehemiah, and 1 Esdras being the other three), was originally written in Greek,[3] and probably entitled ἀποκάλυψις Ἔσδρα (so Fritzsche; but Hilgenfeld argues for Ἔζρας ὁ προφήτης). With the exception of inconsiderable fragments, the original (Greek) text has been lost; but numerous ancient translations still testify to the wide-spread popularity which the work enjoyed during the earlier centuries of the Christian era. Five distinct versions are now known to scholars,—the Latin, Syriac, Ethiopic, Arabic, and Armenian. Of these the Latin is the oldest and the best. In most of its MSS., and in all the eastern versions, the first two and the last two chapters of the received Vulgate text are omitted; and eighty-three verses are inserted between vii. 35 and vii. 36. The genuineness of these verses cannot be doubted; they were known to Ambrose, Vigilantius, and Jerome, and in 1875 were rediscovered by Bensly in a MS. of the 9th century. The four chapters just mentioned Fritzsche proposes to call the fifth book of Ezra. They are certainly distinct from the original 2 Esdras, and are by general consent assigned to a Christian authorship of or near the 3d century.

The apocalyptic character of 2 Esdras has already been indicated (vol. ii. p. 154–5). Its seven visions all have reference to the future of Jerusalem, the central question being whether and when the city is to be restored and its enemies punished. The fifth vision (xi. 1–xii. 51) is of chief importance to the critic; his conclusions upon the date and origin of the book must depend almost entirely upon his interpretation of the symbolical eagle, the wings, the feathers, and the heads there described. According to Laurence, C. J. van der Vlis and Lücke (2d edition), the vision is to be explained as having reference to the whole course of Roman history from Romulus to Julius Cæsar. The three heads are Sulla, Pompey, and Cæsar; and the work was composed about the time of the assassination of the last-named. Hilgenfeld, in his earlier interpretation of the vision (1857), referred it to the Ptolemies; but in 1867 he substituted the Seleucidæ, while adhering to his original opinion that the three heads are Cæsar, Antony, and Octavian, and that the work was written immediately after the death of Antony. The majority of modern critics believe that Rome under the empire is intended; but there are numerous differences as to the details of this interpretation. Gutschmid and some others identify the three heads with Septimius Severus, Caracalla, and Geta, thus placing the date of the composition of this part of the work as late as the year 218 A.D.[4] But the more general opinion since

---

[1] Unless by ὁ ποιμήν or *Pastor* of Athanasius (*Epistola festalis*), Hugo a S. Caro, and others this book be meant. But it is more probable that the "Shepherd" of Hermas is intended. See De Wette-Schrader, *Einl.*, sec. 31, note *b*. By Augustine's "Esdræ libri duo" (*De Doctr. Chr.* ii. 8) we are probably to understand our Ezra and Nehemiah; but compare *De Civ. Dei*, l.c.

[2] Though it begins there with the words "Liber Esdræ prophetæ secundus." In the Syriac, Arabic, and Ethiopic versions it is styled the *first* of Ezra. In the Armenian it is the *third*.

[3] Ewald is almost alone in claiming for it a Hebrew original (*Gesch.* vii. 69). See also Derenbourg, *Revue critique* for 1876, p. 132.

[4] Gutschmid agrees with Hilgenfeld as to the date of the rest of the work.

Corrodi (1781) has been that the three Flavian emperors, Vespasian, Titus, and Domitian, are intended by that symbol. Corrodi himself and Ewald assign the book to the reign of Titus; Volkmar, Langen, and Renan to that of Nerva; and Gfrörer, Dillmann, Wieseler, and Schürer to that of Domitian. On the whole, it may be said that there is a growing consensus of opinion in favor of a date somewhere between 81 and 97 A.D.

As upon the question of date, so upon the question of authorship, critics are now more nearly agreed than formerly in the belief that the book belongs to the Jewish cycle of apocalyptic literature, and that its author was probably a Pharisee, and possibly one who may have fought on the walls of Jerusalem in the final struggle. It is, indeed, strongly, even fiercely, Jewish in its sympathies; and it is not a little remarkable that it should have made so little impression upon the Jewish mind, while by the Christians, on the other hand, it was received with great respect, and was indebted to them for its preservation. It has not passed through their hands without alteration. The insertion of the word "Jesus" in chap. vii. 28 may be mentioned as an instance of the changes it has undergone.

By the author of the epistle of Barnabas (chap. xii.), by Clement of Alexandria (*Strom.* iii. 16), by Tertullian (*De hab. mul.*, 3), and by Ambrose (*De Bono Mortis*, chap. x.–xii.), 2 Esdras is referred to as prophetic Scripture. The unfavorable judgment of Jerome upon both books of Esdras is on the other hand repeated with special emphasis with regard to this in his treatise against Vigilantius. The work was never included in any list of canonical or "ecclesiastical" writings, nor did it generally appear in MS. Latin Bibles. It was printed, however, in Pfister's Bamberg Latin Bible (1460), and frequently thereafter. To this circumstance, doubtless, it owes its somewhat too high position, both in the Protestant and in the Romish Apocrypha. It may be interesting to notice that Columbus drew from chap. vi. 42 one of the arguments by which he supported his cause in the conference of Salamanca in 1487 (Navarrete, *Coleccion*, ii. 261).

It cannot be doubted that 2 Esdras has exercised considerable influence on the course of Christian thought, especially on eschatological subjects; but in cases of real coincidence between its teaching and that of Paul, the honor of priority is now very generally conceded to the canonical writer. The work is of great authority in some Oriental churches; and it has been a special favorite with many Western mystics, such as Schwenkfeld and the once famous Antoinette Bourignon.

Tischendorf, in his *Apocalypses Apocryphæ*, prints a Greek Apocalypse of Esdras, which is to be distinguished from 2 Esdras. It seems to date from the 3d century of the Christian era, and to belong originally to the Christian cycle (see vol. ii. p. 157).

The best commentary on 1 Esdras is that of O. F. Fritzche in the *Exegetisches Handbuch* (Leipsic, 1851). See also his critical edition of the text *Libri apocryphi Veteris Testamenti græce cum commentario critico* (Leipsic, 1871); De Wette-Schrader, *Einleitung*, sects. 363–4 (1869); Schürer in Herzog's *Encyklopädie*, i. 496 (1877).—There have been several critical editions of the Latin text of 2 Esdras, the earliest having been those of Fabricius (1741) and Sabatier (1751). Laurence was the first editor of the Ethiopic version (Oxford, 1820), Ewald of the Arabic (Göttingen, 1863), and Ceriani of the Syriac (Milan, 1868). The Vatican codex of the Arabic has now for the first time been edited by Gildemeister (Bonn, 1877). The Armenian is to be found in the Armenian Bible (Venice, 1805). The latest editions of the Latin are those of Hilgenfeld (1869) and of O. F. Fritzche (*Libri Apocryphi*, as above). A good account of the work, with an almost exhaustive catalogue of the modern literature of the subject, is given by Schürer in his *Neutestamentliche Zeitgeschichte* (Leipsic, 1874). In 1875 Bensly published the results of an examination of the Amiens MS., which dates from the 9th century. The missing fragment has also been found in a Spanish MS. (see *Cambridge Journal of Philology*, 1877). See also Renan, *Les Évangiles* (Paris, 1877), and Drummond, *The Jewish Messiah*, (London, 1878).

(J. S. BL.)

ESHER, a village and parish in the county of Surrey, England, is situated about 15 miles S.W. of London. Near it is Claremont Palace (built by the great Lord Clive), formerly the residence of the Princess Charlotte, and more recently of Louis Philippe and his family. Of the mansion house of Esher, in which Cardinal Wolsey resided for three or four weeks after his sudden fall from power in 1529, only the gate-house now remains. A new mansion was erected in 1803. Esher church contains some fine memorials, and one of its three bells is said to have been brought from San Domingo by Sir Francis Drake. The population of the parish in 1871 was 1815.

ESHREF, or ASHREF, a town of Persia in the province of Mazanderan, about 50 miles west of Astrabad, and 5 miles inland from the Caspian Sea. It lies in a hollow of the mountains richly embowered with cypress, orange, and melon trees. The inhabitants, who number about 5000 or 6000, comprise, according to Napier, the descendants of a Georgian colony introduced by Shah Abbas Sefawi, some families of Talish and Tats (the former a Turkish, the second a Persian tribe), and a number of Godars, a peculiar pariah race, possibly of Indian origin. Foreign trade, especially with Constantinople and Astrakhan, is carried on by means of the port of Mashhad-i-Sar, about 50 miles to the N.W., the exports being cotton, sugar, and cutlery, and the imports iron vessels and crockery. The principal buildings are the two dilapidated royal palaces. They were built in a style of great magnificence by Shah Abbas, and after a conflagration were restored by Shah Nadir, the conqueror of Delhi. The third palace of Sefiabad, situated on an eminence above the town, has been replaced by a modern building in the European style.

For details see *Erinnerungen aus dem Leben des K. Russischen Gen.-Lieut. Johann von Blaramberg*, 1874, quoted in Petermann's *Mittheil.*, 1875; and Napier's "Diary of a Tour in Khorassan," in *Journ. of Roy. Geog. Soc.*, 1876.

ESKI-DJUMA, or ESKI-DJUMUA, a town of Bulgaria, in the sanjak of Rustchuk, about 22 miles west of Shumla, on the northern slopes of the Binar-dagh. It has several mosques and baths, and derives great local importance from its fairs, of which the greatest, in May, is attended by a vast concourse of merchants from north and south, and displays a variety of German, French, Swiss, and Russian goods.

See Hilberg, *Nach Eski Djumaia, mit Bericht über die Messe von Eski Djumaia im Mai, 1876, von s. Exc. Gr. Edmund Zechy*, Vienna, 1876.

ESKILSTUNA, a town of Sweden in the government of Södermanland, and district of Nykoping, on the Hjelmar-Aa, which unites Lake Hjelmar with Lake Malar. It is the principal centre of Swedish manufacturing industry, possessing a royal musket-factory, engineering works, cutlery establishments, needle factories, dye-works, and tanneries. The place is mentioned in the 13th century, and is said to derive its name from an English missionary called Eskil who suffered martyrdom and was buried on the spot. It rose into importance in the reign of Charles X., who bestowed on it considerable privileges, and gave the first impulse to its manufacturing activity. Population 6130.

ESKIMO, ESKIMOS, or ESQUIMAUX, the name applied by European ethnologists to a large number of cognate but widely separated tribes, which are scattered along the coasts of the arctic regions of America and Asia. The Danish form of the word has recently supplanted the older French form. The name is a corruption of the Abenaki Indian *Eskimatsic* or the Ojiba *Askimeg*, both terms meaning "those who eat raw flesh." The native name is *Innuit*—a word signifying, as names of savage tribes frequently do, "*The* people." The Eskimo constitute a very homogeneous race, and are the widest spread aboriginal people in the world. They are entirely unknown in Europe, being confined to the arctic coast of America, and a small portion of the Asiatic shore of Behring Strait. On the American shores they are found, in broken tribes, from East Greenland to the western shores of Alaska,—never far off the coast, or south of the region where the winter ice allows seals to congregate in large numbers. They thus stretch for 3200 miles from S.E. to S.W.; and though in all likelihood they have little intercourse with each other, yet, judging from the traditions, the separate tribes must have maintained their present characteristic language and mode of life for at least 1000 years. Most probably, like the rest of the aborigines of the New World, they came from Asia at some very remote period. The N.W. American Coast Indians, whose modes of life are much the same as the Eskimo, bear a striking resemblance to them in appearance. The Eskimo may thus have been fishing Indians, who formerly lived on the banks of the great rivers which flow into the Polar Ocean, and were gradually driven seaward by the more southern Indians, against whom they to this day maintain a violent enmity. In the course of their migrations they arrived in Grinnell Land, crossed Smith Sound, not further north than Cape Union, according to Nares, then advanced gradually southward along the west coast of Greenland, doubled Cape Farewell, and spread up the east coast as far north as man has yet reached. They may have rounded, with the musk ox and the lemming, the north end of Greenland, but the probabilities are in the direction indicated. Even on hunting expeditions they rarely withdraw more than 20 miles from the coast, and only in very exceptional cases 30 miles. Save a slight admixture of European settlers, they are the only inhabitants of both sides of Davis Strait and Baffin's Bay. They extend as far south as about 50° N. lat. on the eastern side of America and in the west to 60° on the eastern shore of Behring Strait, while 55° to 60° are their southern limits on the shore of Hudson's Bay. Throughout all this range no other tribes intervene, except in two small spots on the coast of Western America, where the Kennayan and Ugalenze Indians come down to the shore for the purpose of fishing. The Aleutians are closely allied to the Eskimo in habits and language, though their culture is somewhat more highly developed. Rink divides them into the following groups, the most eastern of which would have to travel nearly 5000 miles to reach the most western. 1. The East Greenland Eskimo, few in number, every year advancing further south, and having intercourse with the next section. 2. The West Greenlanders, civilized, living under the Danish crown, and extending from Cape Farewell to 74° N. lat. 3. The Northernmost Greenlanders—the Arctic Highlanders of Ross—confined to Smith, Whale, Murchison, and Wolstenholme Sounds, north of the Melville Bay glaciers, not extending to the western shores of the former strait, nor within the memory of man having any intercourse with those south of them. They are very isolated, have greatly decreased of late years, did not until recently possess the kayak or skin-covered canoe, the umiak or open skin boat, or the bow and arrow, are bold hunters, pagans, and are perhaps the most typical of the Eskimo in Greenland; they have not of recent years greatly decreased, though at present they do not number more than 200.[1] 4. The Labrador Eskimo, mostly civilized. 5. The Eskimo of the middle regions, occupying the coasts from Hudson's Bay to Barter Island, beyond Mackenzie River—perhaps comparatively a rather heterogeneous group, inhabiting a stretch of country 2000 miles in length and 800 in breadth. 6. The Western Eskimo, from Barter Island to the western limits in America. They differ somewhat from the other groups in various habits, such as the use of the baidar or double-manned skin-covered canoe, in the clothing of the men, in their labrets, and in the head-dress of the women. They are allied to the Aleutians and the Indians of Alaska. 7. The Asiatic Eskimo or Tuski, who are again nearly allied to the Namollo and Itelmes. None of the Arctic tribes of Europe or Asia have the slightest connection with them. Of all the Eskimo those of Greenland and Labrador are the best known; the others are known but partially.

Appearance and Dress.—The Eskimo are not so small as they are usually represented, their height—5 feet 4 inches to 5 feet 10 inches, and in rare cases even 6 feet—being quite up to the average of the coast Indians. Their dress, however, gives them a dwarfish appearance. Both men and women are muscular and active, the former often inclining to *embonpoint*, and both having a pleasing, good-humored, and, not unfrequently, even handsome cast of countenance, apt to break into a "grin" on very small provocation. The face is broadly oval, flat, with fat cheeks; forehead not high, and rather retreating; teeth good, though, owing to the character of the food, worn down to the gums in old age; nose very flat; eyes rather obliquely set, small, black, and bright; head largish, and covered with coarse black hair, which the women fasten up into a top-knot on their crown, and the men clip in front and allow to hang loose and unkempt behind. Their skulls are of the mesocephalic type, the height being greater than the breadth; according to Davis, 75 is the index of the latter and 77 of the former. Some of the tribes slightly compress the skulls of their new-born children laterally (Hall), but this practice is a very local one. The men have usually a slight moustache, but no whiskers, and rarely any beard. The skin has generally a "bacony" feel, and when cleaned of the smoke, grease, and other dirt—the accumulation of which varies according to the age of the individual—is only so slightly brown that red shows in the cheeks of the children and young women. The people soon age, however. Their hands and feet are small and well formed, and, as a rule, they have a more pleasing appearance than all except the best-looking Indian tribes. The women and children dress entirely in skins of the seal, reindeer, bear, dog, or even fox, the first two being, however, the most common. The men and women's dress is much the same. The jacket of the men has a hood, which in cold weather is used to cover the head, leaving only the face exposed; it must be drawn over the head, as it has no opening in front or behind. The women's jacket has a fur-lined "amowt" or large hood for carrying a child, and an absurd looking tail behind, which is, however, usually tucked up. The trousers are either tight or loose, and are fastened into boots made of prepared seal skin, very ingeniously and neatly made. The women's trousers are usually ornamented with eider duck necks, or embroidery of native dyed leather; their boots, which are of white leather, or (in Greenland) dyed of various colors, reach over the knees, and in some tribes are very wide at the top, thus giving them an awkward appearance and a clumsy waddling walk. In winter there are two suits of clothes of this description, one with the hair inside, the other with it outside. They also sometimes wear shirts of bird-skins, and stockings of dog or young reindeer skins. The boots require to be changed when wet, otherwise they would freeze hard in cold weather. Their clothes are like all the Eskimo articles of dress or tools, very neatly made, fit beautifully, and are sewn with "sinew-thread," with a bone needle if a steel one cannot be had. In person the Eskimo are usually filthy, water not often coming in contact with them unless accidentally. The children when very young are, however, sometimes cleaned by being licked with their mother's tongue before being put into the bag of feathers which serves as their bed, cradle, and blankets.

Dwellings, Occupations, Characteristic Implements, and Food.—In summer the Eskimo live in conical skin tents, and in winter usually in half-underground huts (*igloos*) built of stone, turf, earth, and bones, entered by a long tunnel-like passage, which can only be traversed on all fours. Sometimes, if residing temporarily at a place, they will erect neat round huts of blocks of snow with a sheet of ice for a window. These, however, though comfortable in the winter, become damp and dripping in the spring, and are then deserted. In the roof are deposited their spare harpoons, etc.; and from it is suspended the steatite basin-like lamp, the flame of which, the wick being of moss, serves as fire and light. On one side of the hut is the bench which is used as sofa, seats, and common sleeping place. The floor is usually very filthy, a pool of blood or a dead seal being often to be seen there. Ventilation is almost non-existent; and after the lamp has blazed for some time, the family having assembled, the heat is all but unbearable: the upper garment must be taken off, and the unaccustomed visitor gasps half asphyxiated in the mephitic atmosphere. In the summer the wolfish-looking dogs lie outside on the roofs of the huts, in the winter in the tunnel-like passage just outside the family apartment. The Western Eskimo build their houses chiefly of planks, merely covered on the outside with green turf. The same Eskimo have, in the more populous places, a public room for meetings. "Council chambers" are also said to exist in Labrador, but are only known in Greenland by tradition. Sometimes in South Greenland and in the Western Eskimo country the houses are made to accommodate several families, but as a rule each family has a house to itself.

The Eskimo are solely hunters and fishers, and derive most of their subsistence from the sea. Their country will allow of no cultivation worth attending to; and beyond a few berries, roots, etc., they use no vegetable food. They are essentially sarcophagous. The seal, the reindeer when obtainable, and various cetaceous animals supply the bulk of their food, as well as their clothing, light, fuel, and frequently also, when driftwood is scarce or unavailable, the material for various articles of domestic economy. The shuttle-shaped canoe or *kayak*, covered with hairless seal-skin stretched on a wooden or whalebone frame, with only a hole in the centre for the paddler, is one of the most characteristic Eskimo implements. The paddler propels it with a bone-tipped double-bladed paddle, like that used in the "canoes" familiar as aquatic playthings in England. He is covered with a waterproof skin or entrail dress, tightly fastened round the mouth of the hole in which he sits, so that, should the canoe overturn, not a drop of water may enter. A skilful kayaker can turn a complete somersault, boat and all, through the water. The *umiak* or flat-bottomed skin luggage-boat, rowed by the women, is another, though less interesting Eskimo vessel. The sledge, made of two runners of wood or bone,—even, in one case on record, of frozen salmon (Maclure),—united by cross bars tied to the runners by hide thongs, and drawn by from 4 to 8 dogs harnessed abreast, is another article of Eskimo domestic economy, which no European ingenuity has ever been able to improve. Some of their weapons afford remarkable evidence of inventive skill,—in particular, the harpoon with the point detachable after it has struck the seal, narwhal, or white whale; the line to which the harpoon is fastened, with the inflated seal skin at the end, which tires out the prey, besides marking its course, and buoys it up when dead; the bird-spears, with bladder attached, and the adventitious side-points which strike the animal should the main one miss it; the rib bow of the wild Eskimo, etc. Although they have to maintain a severe struggle for existence against the elements, the Eskimo have been able, in the manufacture of their tools, to develop artistic and mechanical skill far surpassing that of savages more favorably situated, but less endowed with brain power. They sometimes cook their food by boiling, but, when it is frozen, never hesitate to devour it raw. Blood, and the half-digested contents of the reindeer's paunch, are also eagerly consumed by them; but it is a mistake to suppose that they habitually eat blubber. Fat they are no doubt fond of, but blubber is too precious: it must be kept for winter fuel and light. They are enormous eaters; two Eskimo will easily dispose of a seal at a sitting; and in Greenland, for instance, each individual has for his daily consumption, on an average, 2½ ℔ of flesh with blubber, and 1 ℔ of fish, besides mussels, berries, sea-weed, etc., to which in the Danish settlements may be added 2 oz. of imported food. Ten pounds of flesh, in addition to other food, is not uncommonly consumed in a day in time of plenty. A man will lie on his back and allow his wife to feed him with tit-bits of blubber and flesh until he is unable to move.

---

[1] A party of Eskimo from the western side of Smith Sound, about Cape Isabella, crossed over in a umiak and five kayaks, about five years before the survivors of the crew of the "Polaris" wintered there in 1872–3. They introduced the use of the bow and arrow, hitherto unknown among the "Arctic Highlanders."

The Eskimo cannot be strictly called a wandering race. They are nomadic only in so far that they have to move about from place to place during the fishing and shooting season, following the game in its migrations. They have, however, no regular property. They possess only the most necessary utensils and furniture, with a stock of provisions for less than one year; and these possessions never exceed certain limits fixed upon by tradition or custom (Rink). Long habit and the necessities of their life have also compelled those having food to share with those having none,—a custom which, with others, has conduced to the stagnant condition of Eskimo society and to their utter improvidence.

Moral and Mental Character.—So far as a nation can be characterized in a few words, it may be said that the Eskimo are, if not in the first rank of barbarous races, not in the last, and that, though they want some of the mental endowments of races like the Polynesians, they are equally free from many of their vicious traits. Their intelligence is considerable, as their implements and folk-tales abundantly prove. They display a taste for music, chartography, and drawing, display no small amount of humor, are quick at picking up peculiar traits in strangers, and are painfully acute in detecting the weak points or ludicrous sides of their character. They are excellent mimics, and easily learn the dances and songs of the Europeans, as well as their games, such as chess and draughts. They gamble a little,—but in moderation, for the Eskimo, though keen traders, have a deep-rooted antipathy to speculation. When they offer anything for sale—say at a Danish settlement in Greenland—they always leave it to the buyer to settle the price. They have also a dislike to bind themselves by contract. Hence it was long before the Eskimo in Greenland could be induced to enter into European service, though when they do so now-a-days they pass to almost the opposite extreme—they have no will of their own. It is affirmed by those who ought to know that any sort of licentiousness or indecency which might give rise to public offence is rare among them. In their private life their morality is, however, not high. The women are especially erring; and in Greenland, at places where strangers visit, their extreme laxity of morals, and their utter want of shame, are not more remarkable than the entire absence of jealousy or self-respect on the part of their countrymen and relatives. Theft in Greenland is almost unknown; but the wild Eskimo make very free with strangers' goods—though it must be allowed that the value they attach to the articles stolen is some excuse for the thieves. Among themselves, on the other hand, they are very honest,—a result of their being so much under the control of public opinion. Lying is said to be as common a trait of the Eskimo as of other savages in their dealings with Europeans. They have naturally not made any figure in literature. Their folk-lore is, however, extensive, and that collected by Dr. Rink shows considerable imagination and no mean talent on the part of the story-tellers. In Greenland and Labrador most of the natives have been taught by the missionaries to read and write in their own language. Altogether, the literature published in the Eskimo tongue is considerable. Most of it has been printed in Denmark, but some has been "set up" in a small printing office in Greenland, from which about 280 sheets have issued beside many lithographic prints. A journal (*Atuagagldliutit nalinginarmik tusaruminásassumik univkat*, *i.e.*, "something for reading, accounts of all entertaining subjects") has been published since 1861. Up to 1874 it extended to 194 sheets in 4to, and about 200 leaves with illustrations. Two Eskimo have appeared as authors on a small scale, the last being Hans Hendrik, who has published an autobiography, narrating his life among the Smith Sound Eskimo, and as the hunter of the expeditions of Kane, Hayes, Hall, and Nares. Some of them pick up handicrafts very readily, and those who have wrought in the Copenhagen workshops are said by their employers to learn various kinds of labor more rapidly than average Danish youths of the same age.

Religion.—The Eskimo nearly everywhere hold the same religious ideas, though in Greenland and Labrador they are, with few exceptions, nominally at least, Christians. The whole world is, according to the pagan Eskimo's belief, governed by *inuas*, supernatural powers or "owners," each of whom holds his sway within natural limits. Any object or individual may have its, his, or her *inua*, though generally speaking the idea of an *inua* is limited to certain localities or passions—such as a mountain or lake, or strength or eating. The soul, for instance, is the *inua* of the body. The earth and the sea rest on pillars, and cover an underworld accessible by various mountain clefts or by various entrances from the sea. The sky is the floor of an upperworld to which some go after death, while others—good or bad—have their future home in the under-world. Here are the dwellings of the *arsissut*—the people who live in abundance. The upper one, on the contrary, is cold and hungry; here live the *arssartut* or ball-players, so called from their playing at ball with a walrus head, which gives rise to the aurora borealis. The mediums between the *inua* and mankind are the *angakoks* (Esk. plur., *angakut*) or wizards, who possess the peculiar gift of *angakoonek*—or the state of "being angakok"—which they have acquired by the aid of guardian spirits called *tornat* (plural of *tŏrnak*), who again are ruled by *tornarsuk*, the supreme deity or devil of all. Such is their religion in the barest possible outline. They also invoke a supernatural influence which is called *kusiunek* or *iliseenek*, which may be translated as witchcraft: this is believed to be the mystic agency which causes sudden sickness or death. In the folk-lore of the Greenlanders, as of other nations, divine justice manifests itself chiefly in the present life, though they have a faint belief in reward or punishment in the future world, according as the individual has behaved in this.

Language.—The idiom spoken from Greenland to North-eastern Siberia is, with a few exceptions, the same; any difference is only that of dialect. It differs from the whole group of European languages, not merely in the sound of the words, but more especially, according to Rink, in the construction. Its most remarkable feature is that a sentence of a European language is expressed in Eskimo by a single word constructed out of certain elements, each of which corresponds in some degree to one of our words. One specimen commonly given to visitors to Greenland may suffice: *Savigiksiniariartokasuaromaryotittogog*, which is equivalent to "He says that you also will go away quickly in like manner and buy a pretty knife." Here is one word serving in the place of 17. It is made up as follows:—*Savig* a knife, *ik* pretty, *sini* buy, *ariartok* go away, *asuar* hasten, *omar* wilt, *y* in like manner, *otit* thou, *tog* also, *og* he says.

Social Economy.—The Eskimo differ from most other tribes of savages, and notably from those of the rest of America, by having no chiefs or political and military rulers. Fabricius concisely decribed them in his day:—"Sine Deo, domino, reguntur consuetudine." The government is mainly a family one, though if a man is distinguished for skill in the chase, strength, shrewdness, or other qualities useful to a wild community, he will no doubt obtain a corresponding influence in the village or settlement. There is also a good deal of dependence of one upon another, as must happen in a people situated as the Eskimo. The family, the inhabitants of a house, and the inhabitants of a wintering place or hamlet are the three subdivisions recognized by the Eskimo; but any connection between the different wintering places is hardly known and is not recognized. They never go to war with each other; and though revengeful, and apt to injure an enemy secretly, they rarely come to blows, and are morbidly anxious not to give offence. Indeed, in their intercourse with each other they indulge in much hyperbolical compliment, and language courteous from the teeth outwards. But they are not without courage. On the Coppermine and Mackenzie Rivers, where they sometimes come into collision with the Indians, they fight fiercely, and are a name of terror. Polygamy is rare, but the rights of divorce and re-marriage are exercised among the wild Eskimo without any definite restriction. The courtship or marriage customs and the laws of inheritance will be found fully described in the works mentioned in the bibliography. The chief laws are such as the following. Every seal caught at a wintering place should be equally divided as far as it will go. Any one picking up driftwood has only to put some stones on it, as it lies on the shore, to establish his ownership in it. If a seal is harpooned and gets off with the harpoon sticking in it, the first owner loses his right in it if the bladder float gets detached. Any other kind of goods found are the property of the owner. If two hunters at the same time hit a bird, the bird is equally divided between them. All kind of game which is very large or rare is common property. In South Greenland whoever is the first to see a bear has ownership in it, no matter who kills it. The borrower is not bound to give compensation for any injury to the tools of another which he may have borrowed. If a man repent of a bargain he has a right to retract; nothing is sold on credit, or at least without being repaid in a short time. The Greenlanders were always fond of festivals, as are the Eskimo to this day all over their country. When they met each other they used to rub noses together, but this, though a common custom still among the wild Eskimo, is entirely abandoned in Greenland except for the petting of children. There is, in Greenland at least, no national mode of salutation, either on meeting or parting. When a guest arrives or enters a house, commonly not the least sign is made either by him or his host. On leaving a place they now sometimes say "inûvdluaritse," *i.e.*, live well, and to a European "aporniakinatit," *i.e.*, do not hurt thy head, viz., against the upper part of the doorway.

Population.—No precise statement can be made regarding the numbers of the Eskimo race. For Greenland, however, we have exact data so far as the Danish possessions are concerned. In 1870, the date of the last census, there were, from Cape Farewell to the limit of the West Greenland region, 9588 people. Add to this about 200 for Smith's Sound, and say 400 for East Greenland, and the whole population of that island continent—inhabited and habitable on the coast only—will not be many more than 10,000. On an average, the proportion of females to males in Greenland has been 1118 to 1000, while in Iceland it is 1102, and in Denmark and the Faroe Isles there are 1018 to 1000 males. The natives of Greenland have decreased since the Danes came into the country, and at present the population is at a stand-still. On a rough estimate, the whole Eskimo race does not, it is believed, exceed 40,000. But we have really no data, except at spots where they have come in contact with Europeans.

Bibliography.—Fragmentary notices of the Eskimo may be found in numerous works. We need only take cognizance here of modern writers who have actually lived among the Eskimo. These are:—Rink, *Eskimoiske Eventyr og Sagn* (1866); Supplement to the same work (1871); *Tales and Traditions of the Eskimo* (1875); *Danish Greenland: its People and its Products* (1877); *Grönland, geographisk og Statistisk beskrevet*, 2 vols. (1857); *Om Eskimoernes Herkomst* (Aarbog for Nord. Oldk. og. Hist. 1871, pp. 269–302); Richardson, *Polar Regions* (1861), pp. 298–321; Markham, *Arctic Papers of the R. G. S.* (1875), pp. 163–232; Simpson, *Ibid.*, pp. 233–275; *Hans Hendriks the Eskimo's Memoirs* ("Geographical Magazine," Feb., 1878, *et seq.*); Brown, *Races of Mankind*, vol. i. (1872), pp. 5–20; *Countries of the World*, vol. i. (1877), pp. 123–144. See also the works and papers referred to in the foregoing works; the dictionaries and grammars of Fabricius, Washington, Kleinschmidt, and Janssen, and a sketch of the Eskimo language by Dr. Rink in course of publication by the Smithsonian Institution; and finally the various narratives and other official reports and papers of the Arctic voyagers, particularly those of Parry, Lyons, Franklin, Collinson, M'Clure, Graah, Kane, Rae, Hayes, Hall, Bessels, Koldeway, and Nares. (R. B.)

ESKI-SAGRA, or ESKI-ZAGRA, a town of European Turkey, province of Adrianople, is pleasantly situated on the southern slope of the Balkans, 70 miles N.W. of Adrianople. The vicinity is highly cultivated, and there are some well-frequented hot mineral baths. Eski-Sagra has 13 mosques, several Christian churches, and a bazaar. Its principal manufactures are carpets, coarse cloth, and leather. In the Russo-Turkish war of 1877, while occupied by the Russians, it was threatened by the Turks under Suleiman Pasha, and General Gourko advancing to its relief suffered a disastrous defeat (July 31). The Russians were compelled to evacuate the town, and retire through the Lower Balkans, after which it was set on fire by the Turks, and great barbarities were perpetrated on the Christian inhabitants. The population of the town numbered about 20,000.

ESKI-SHEHR, a town of Asiatic Turkey, in Asia Minor, in the sanjak of Sultan Oegni, about 80 miles S.E. of Broussa, and 130 miles W.N.W. of Angora, to the south of the Purssak-Chai, a tributary of the Sangarius, in 30° 32′ E. long. and 39° 43′ N. lat. It consists of two portions, the town proper and the market-town, united by a causeway about a mile and a half in length. There are at least eight or ten mosques; and the market town contains three or four natural warm baths, which are mentioned as early as the 3d century by Athenæus. About 18 miles to the east are extensive deposits of meerschaum, which yield a yearly revenue to the Government of about 60,000 piastres. The clay is partly manufactured into pipes in the town; but the greater proportion finds its way to Europe and especially to Germany. The annual export is estimated at 2200 or 2500 chests, of a total value of 35 million piastres. Eski-Shehr, *i.e.*, the old town, is identified with the ancient Dorylæum of Phrygia, and it still preserves some sculptures of the Roman period. Its name appears about 302 B.C., in connection with the wars of Lysimachus and Antigonus; and it is frequently mentioned by the Byzantine historians as an imperial residence and military rendezvous. In 1097 it was the scene of the defeat of the Turks under Kilidj-Arslan by the crusaders under Geoffrey of Bouillon.

ESNEH, or ISNE, the Latopolis of the Greeks, a town of Upper Egypt, on the left bank of the Nile, 28 miles S.S.W. of Thebes, in 25° 17′ 38″ N. lat. and 33° E. long. Its position at the upper end of the Nile valley, which here widens out to a breadth of 4½ miles, is greatly in its favor, and it forms an important dépôt in the caravan trade from Sennaar. The local manufactures are shawls, cottons, and pottery. It has frequently served as a place of refuge for the political exiles of Southern Egypt, and at the time of the French expedition it was occupied by the Mamelukes of Hassan, Osman, and Saleh Bey. More recently it has been the custom to transport thither female offenders from Cairo. To the south of the town lies a Coptic monastery, which attracts a large number of pilgrims from far and near to visit the relics of the martyrs who were put to death at Esneh during the Diocletian persecution, 303 A.D. The population of the town is estimated at 30,000. For an account of the ancient temple of Kneph, see EGYPT, vol. vii., p. 678.

ESPARTO, or SPANISH GRASS, *Macrochloa* (*Stipa*, L.) *tenacissima*, Kunth, is a plant of the tribe *Stipeæ*, resembling the ornamental feather-grass of gardens. It is indigenous to the south of Spain and the north of Africa, and is especially abundant in the sterile and rugged parts of Murcia and Valencia, and in Algeria, flourishing best in sandy, ferruginous soils, in dry, sunny situations on the sea coast. Pliny (*N. H.* xix. 2) described what appears to have been the same plant under the name of *spartum*, whence the designation *campus spartarius* for the region surrounding New Carthage. (See Cartagena, vol. v. p. 123.) It attains a height of three or four feet. The stems are cylindrical, and clothed with short hair, and grow in clusters of from two to ten feet in circumference; when young they serve as food for cattle, but after a few years' growth acquire great toughness of texture. The leaves vary from six inches to three feet in length, and are gray-green in color; on account of their tenacity of fibre and flexibility they have for centuries been employed for the making of ropes, sandals, baskets, mats, and other articles. Ships' cables of esparto, being light, have the quality of floating on water, and have long been in use in the Spanish navy. Esparto leaves contain 56 per cent. by weight of fibre, or about 10 per cent. more than straw, and hence have come largely into requisition as a substitute for linen rags in the manufacture of paper. For this purpose they were first utilized by the French, and in 1857 were introduced into Great Britain. In 1877 the total imports of esparto into the United Kingdom were 174,720 tons, being 43,809 tons in excess of the quantity imported in the previous year. When required for paper-making the leaves should be gathered before they are quite matured; if, however, they are obtained too young, they furnish a paper having an objectionable semi-transparent appearance. The leaves are gathered by hand, and from two to three hundredweight may be collected in a day by a single laborer. They are generally obtained during the dry summer months, as at other times their adherence to the stems is so firm as often to cause the uprooting of the plants in the attempt to remove them. Esparto may be raised from seed, but cannot be harvested for twelve or fifteen years after sowing. The increased demands of the paper trade have led to forced cropping in some districts, where in consequence there has been a falling off of from 2 to 10 per cent. in production. For the processes of the paper manufacturer esparto is used in the dry state, and without cutting; roots and flowers and stray weeds are first removed, and the material is then boiled with caustic soda, washed, and bleached with chlorine solution. Sundry experiments have been made to adapt esparto for use in the coarser textile fabrics. Messrs. A. Edger and B. Proctor (see *Chem. News*, vol. xxxv. p. 141, 1877) have directed attention to the composition of the slag resulting from the burning of esparto, which they find to be strikingly similar to that of average medical bottle glass, the latter yielding on analysis 66·3 per cent. of silica and 25·1 per cent. of alkalies and alkaline earths, and the slag 64·6 and 27·45 per cent. of the same respectively. For further details concerning the manufacture of paper from esparto, see the article Paper.

ESPINASSE. See L'Espinasse.

ESPINEL, Vicente (1551?–1634?), a Spanish poet and ecclesiastic, born probably in 1551, at Ronda, in the province of Granada. He was educated at Salamanca, was an early patron and friend of Lope de Vega, and served as a soldier in Flanders. His ecclesiastical position seems to have been that of a chaplain at Ronda, but he resided chiefly at Madrid. He is now chiefly noted as having produced one of the best of those romances delineating Spanish manners that have found imitators in other countries. This book, which is entitled *Relaciones de la Vida y Hechos del Escudero Marcos de Olregon*, appeared in 1618 at Barcelona, at a period when Spanish literature was at a low ebb. Marcos is not a chivalresque "esquire," but a simple individual who seeks his fortune by attaching himself to great men; and the object of the author is to warn young men against so degrading a course of life. The squire tells his own story. The incidents, which are not generally exciting, though amusing, and nationally characteristic, are supposed to be drawn in great part from the author's own life; the style is correct, though somewhat diffuse. Its chief interest, like that of the clever *Vida y Hechos del Picaro Gusman de Alfarache* of Aleman, is that Le Sage has not scrupled to borrow from both writers many of the incidents and characters in his novel of *Gil Blas*—a circumstance which induced an indignant Spaniard to give to his translation into Spanish of Le Sage's work the title, *Gil Blas restored to his Country and his Native Tongue*, while in the preface he denounces the barefaced plagiarism. The charge of plagiarism against Le Sage was first made by Voltaire, who grossly exaggerates in saying that *Gil Blas* is taken entirely from the work of Espinel. Espinel was noted for his musical taste, and added a fifth string to the national guitar. He was also a poet of some reputation, especially for his *Canciones* and *Redondillas*. His pastorals and elegies contain many spirited natural descriptions, though they do not abound in original conceptions; and his versification is always harmonious. He was the inventor or reviver of the measure known as the *decimas*, and sometimes called after him *Espinelas*, which consists of a stanza of ten verses of eight syllables each. He also translated into verse some of the odes and the *Ars Poetica* of Horace. Espinel seems to have been neglected in his old age, for he died in great poverty at Madrid in 1634.

The *Marcos de Olregon* was translated into German by Tieck, with a preface and valuable notes. There is a good English translation by Algernon Langton (2 vols., London, 1816).

ESPRÉMESNIL, or ÉPRÉMÉNIL, Jean Jacques Duval d' (1746–1794), was born in 1746 at Pondicherry, of which colony his father was at that time a member of the general council. He returned to France with his father in 1750, and after completing his studies for the legal profession became king's advocate at Châtelet, and shortly afterwards councillor of the *parlement* of Paris. He was an enthusiastic defender of the rights of the *parlements* against the edicts of Louis XVI.; and having procured from the printers a copy of the edicts of May, 1788, establishing bailiwicks, and re-establishing the *cour plénière* for the trial of those officers of the *parlements* who refused to register the edicts, he revealed this *coup d'état* to an extraordinary assembly of all the chambers, and by a speech of great eloquence induced the magistrates to protest against what they considered the threatened violation of their rights. For this he was arrested, after an exciting scene, while occupying his place in the assembly. The president refused to point him out to the officer charged with his arrest, and each of the other members declared himself to be M. d'Esprémesnil; but at last Esprémesnil, while protesting against the violation of justice implied in his arrest, voluntarily delivered himself up. He was banished to the island of St. Margaret, but when a change took place in the ministry a few months afterwards, he was recalled to Paris. Shortly after his return he was elected a deputy to the States-general, where he soon became as strenuous in his support of the privileges of the king as he had previously been of the privileges of the *parlements;* and after combating, often with a passionateness amounting to violence, the various decrees restraining the royal authority, he at the close of the assembly in 1791 formally protested against the new constitution. In 1792 he was recognized by the revolutionary mob at the Tuileries, and would have suffered summary execution had he not been rescued half dead from the hands of his tormentors by a patrol of the national guard. He obtained temporary refuge in the monastery of St. Germains, and soon afterwards went to Havre, where he lived apparently forgotten till toward the end of 1793, when he was arrested and brought to Paris. He was tried before the revolutionary tribunal, and being condemned to death, was executed 23d April, 1794. (See the histories of the time.)

ESPRONCEDA, José de (1810–1842), a Spanish poet and political agitator, whose life is remarkable for the variety of its incidents. His father was colonel of the Bourbon regiment, and it was while the army was on the march that the boy was born, on the highway near Almendralejo in Estremadura. On the close of the war, his parents settled at Madrid, and he thus had the opportunity of becoming a pupil of Alberto Lista, the professor of literature in St. Matthew's college. Before he was out of his fourteenth year, he had not only attracted his master's attention by his political poems, but had joined a conspiracy against the minister Calomardi. During the imprisonment and seclusion at Guadalajara which this offence brought upon him, he soothed his solitude by singing the fate of Pelayo, the patron of Spanish liberty. On his release he withdrew to Lisbon, only to find himself again imprisoned in the castle of St. George, and to be transported with some of his fellow refugees to England. Here, by one of those turns of fortune which make truth stranger than fiction, he met with a young lady with whom he had fallen in love while in Lisbon; and here too he became, what was perhaps of as much importance for his poetic development, a student of Shakespeare, Milton, and Byron. In 1830 he took part in the July revolution at Paris, and soon after joined the ill-fated expedition of Pablo de Chapalangarra in Spain. On the death of Ferdinand, he was not only allowed to return to his native country, but obtained an appointment in the queen's guards. This, however, he soon forfeited by a political song, and he was banished to Cuellar, where he had leisure to compose a novel in six volumes, called *Don Sancho Saldaña, ó el Castellano de Cuellar.* The publication of the *estatuto real* brought him back to Madrid to write and act with as little caution as ever. He joined the revolutionary movements of 1835 and 1836, and in 1840 entered the national guard as lieutenant. The republican party having come into power in 1840, he was appointed ambassador to the Hague, but was obliged to give up his post through an illness which terminated fatally at Madrid on the 23d of May, 1842. His poetical works were collected by Villalta in 1840, and have been reprinted more than once under the editorship of Hartzenbusch. The "Student of Salamanca," *El estudiente de Salamanca*, is a continuation of the legend of Don Juan, and *El Diablo Mundo* is based on the story of Faust. Of the lyric poems, which are frequently distinguished by great force of expression and skill in versification, the most remarkable are *El Mendigo* or the Beggar, *El Verdugo* or the Headsman, the Hymn to the Sun, and the Ode to Night. (See Ch. de Mazada, *Études sur l'Espagne*, and Quinet, *Vacances en Espagne.*)

ESQUIMAUX. See Eskimo.

ESQUIRE (Lat. *Armiger*, Old Fr. *Escuyer*), originally a military office ranking immediately below a knight, whose attendant he was, and the bearer of his helmet, shield, and lance, in the tournament or in the battlefield. In early times the title was derived from office, not from birth, and was not hereditary; latterly, however, it has come into such general use—or rather abuse—that all distinction it once had, or all rule regulating its use, is quite lost. Esquires may be divided into five classes, thus:—(1) younger sons of peers and their eldest sons; (2) eldest sons of knights and their eldest sons; (3) chiefs of ancient families by prescription; (4) esquires by creation or office, as heralds and sergeants of arms (constituted by receiving the collar of SS), judges, officers of state, naval and military officers, justices of peace, barristers-at-law; (5) esquires who attend the Knight of the Bath on his installation—usually two specially appointed. All these can *legally* use the title.

ESQUIROL, Jean Étienne Dominique (1772–1840), a French physician celebrated for his treatment of the insane, was born at Toulouse in 1772. He began his studies with a view to the church at the seminary of St. Sulpice, Paris, but being compelled by the Revolution to suspend them, he entered the medical service of the army. In 1794 he became a pupil of the military hospital of Narbonne, but as soon as he was able to leave this service he returned to Paris to complete his medical studies. Having attended the lectures of Pinel, he was chosen by that celebrated physician to be his assistant in the Salpêtrière, and also helped him in editing the *Médecine Clinique.* He obtained his doctor's diploma in 1805, and in 1811 became physician of the Salpêtrière. Having from the time that he completed his preparatory studies devoted his chief attention to the treatment of the insane, he commenced in 1817 a course of lectures on that subject, and the revelations he then made of the abuses observed by him in the lunatic asylums of France induced the Government to appoint a commission to inquire into the subject. Esquirol, by his eloquence, his untiring energy and devotion, and the results of his skilful treatment, contributed greatly to the introduction of the humane method of dealing with mental maladies. He also busied himself in designing plans for the various apartments of lunatic asylums; and the asylums of Rouen, Nantes, and Montpellier were built in accordance with his instructions. In 1823 he became inspector-general of the university of Paris for the faculties of medicine, and in 1826 chief physician of the asylum for insane at Charenton. He died at Paris, 13th December, 1840.

Besides contributing to the *Dictionnaire des Sciences Médicales* and the *Encyclopédie des Gens du Monde*, Esquirol is the author of an important work entitled *Des Maladies Mentales, considérées sous les rapports médical, hygiénique, et médico-légal*, 2 vols., Paris, 1838.

ESQUIROS, Henri Alphonse (1814–1876), a French poet, novelist, and politician, was born at Paris in 1814. His first work, a volume of poetry entitled *Les Hirondelles*, was published in 1834, but though it gained the commendation of Victor Hugo, it attracted little other attention, and obtained only a small sale. In 1837 he published a novel entitled *Le Magicien*, and in 1840 an historical romance, *Charlotte Corday.* In the same year appeared *L'Évangile du Peuple*, an exposition of the life and character of Jesus, which represents the founder of Christianity as a democratic reformer. For this publication Esquiros was condemned to eight months' imprisonment, and he beguiled his term of captivity by writing a volume of poetry, entitled *Les Chants d'un Prisonnier*, consisting chiefly of descriptions of circumstances connected with his infancy and youth. Shortly after regaining his freedom he published three socialist tracts, entitled *Les Vierges martyres, Les Vierges folles,* and *Les Vierges sages.* In 1847 appeared *Paris, ou les sciences, les institutions, et les mœurs au XIX^e siècle*, 2 vols. In the same year he published *Histoire des Montagnards*, and in 1851 *Histoire des Martyrs de la Liberté*, two works which obtained a large circulation among the lower classes, and gained for their author such popularity that in 1849 he was elected a representative of the legislative assembly. In 1851, on account of his extremely radical opinions, and his strong opposition to the empire, he was expelled from France. He proceeded first to Holland, and thence, in 1855, to England, where he was for some time professor of French literature at Woolwich. Here he wrote for the *Revue des Deux Mondes* a number of essays on English life and character, which were afterwards translated and published in London, under the title of the *English at Home* (1st series, 1862, 2d, 1863). He also published in 1859 *La Néerlande et la Vie hollandaise.* His works both on England and on Holland are remarkable for fulness of information and sympathetic appreciation of foreign characteristics. In 1869 he was chosen a member of the legislative assembly for the fourth circonscription of the department of the Bouches du Rhône, and took his seat among the democratic opposition. In September, 1870, he was made superior administrator of the department, but on account of his imprudent political prosecutions he was compelled to resign his office in the November following, after which he became editor of the *Égalité* of Marseilles. In 1871 he was chosen a member of the legislative assembly, and sat again on the extreme left. He died at Versailles, May 13, 1876. Esquiros was too much of a partisan to be properly ranked as a statesman, and though he was a brilliant and facile writer, most of his political works are somewhat superficial and declamatory.

ESS, Johann Heinrich van (1772–1847), a Catholic theologian, was born at Warburg, Westphalia, 15th February, 1772. He was educated at the Dominican gymnasium of his native town, and in 1790 entered, as a novice, the Benedictine abbey of Marienminster, in the bishopric of Paderborn. His Benedictine name was Leander. He was priest at Schwalenberg from 1799 to 1812, after which he became extraordinary professor of theology and joint-director of the teachers' seminary at Marburg. In 1818 he received the doctorate of theology and of canonical law. In 1807, in conjunction with his cousin, he published a German translation of the New Testament, and as its circulation was forbidden by the pope, he published in 1808 a defence of his views, entitled *Anszüge aus den Heiligen Vätern und anderen Lehrern der Katholischen Kirche über das nothwendige und nützliche Bibellesen.* An improved edition of this tractate was published in 1816, under the title *Gedanken über Bibel und Bibellehre*, and in the same year appeared *Was war die Bibel den ersten Christen?* In 1818 he published *Die Bibel nicht ein Buch für Priester*, and this was followed in 1819 by a German translation of the Old Testament. In 1822 he resigned his offices at Marburg in order to devote his whole time to the defence of his views regarding Bible reading by the people, and to endeavor to promote the circulation of his Bible translations; and in 1840, conjointly with his pupil Wetzer, he completed a German translation of the Scriptures of the Old and New Testaments. He died at Affolderbach in the Odenwald, 13th October, 1847.

ESSEK, Esseg, or Eszek, a fortress and imperial free town of Austria-Hungary, in the province of Slavonia, and the capital of the county of Verōcze, is situated on the Drave about 135 miles S. by W. of Pesth. It has a Franciscan and a Capuchin monastery, a gymnasium, a military school, a hospital, and an arsenal. It carries on a considerable trade in corn, cattle, and wood, and has also silk manufactories and tanneries. Essek owes its origin to its fortress, which existed as early as the time of the Romans under the name of Mursia. At the beginning of the Hungarian revolution of 1848 the town was held by the Hungarians, but on the 4th February, 1849, it was taken by the Austrians under General Baron Trebersberg. The population in 1869 was 17,247.

ESSEN, a town of Prussia, in the government district of Düsseldorf, province of the Rhine, is situated 19 miles N.E. of Düsseldorf. It is the seat of a court of justice and a board of trade. Among its principal buildings are the town-house, the post-office, the imperial bank, the real school, the two infirmaries, and the hospital. It has also an old Benedictine nunnery founded in 873, and a Catholic church whose choir dates from the 9th century. In the immediate neighborhood of the town there is a beautiful public park. The town owes its prosperity originally to the large coal mines in its vicinity, which employ more than 20,000 workmen, and afford special facilities for its various industries. It has manufactories of woollen and linen goods, vitriol, leather, and machines, but is best known by the cast-steel works of Frederick Krupp, at which are manufactured the famous Krupp cannon. In 1876, 10,500 men were employed in the factory, besides 5000 others in the mines and at the blast furnaces. There were in operation 250 smelting furnaces, 390 annealing and other kinds of furnaces, 77 steam hammers, and 294 steam engines, with a total of 10,000 horse power. In 1875, 612,000 tons of coal and coke were used in the furnaces. The population of Essen has for some time been rapidly increasing; while in 1849 it numbered only 8813, it amounted in 1875 to 54,790.

Essen was formed into a town about the middle of the 10th century by the abbess Hagona, sister of the emperor Henry I. The abbess of the nunnery, holding from 1275 the rank of a princess, governed the town until 1802, when it was incorporated with Prussia. In 1806 it came into the possession of the duchy of Berg, but it was again transferred to Prussia in 1813.

ESSENES, THE, were one of the three principal sects of the Jews, appearing for the first time in Josephus, about the middle of the 2d century before Christ. The historian introduces them along with the Pharisees and Sadducees in his account of the period of Jonathan the Asmonean. As to the circumstances under which they arose, the precise causes in Jewish life to which they owed their origin, and the various stages by which they attained to the elaborate organization of later times, we have no positive information whatever. The accounts we have of them refer particularly to the half century preceding the fall of Jerusalem, when the growth and organization of the sect were complete. Besides the detailed account of Josephus (*Bell. Jud.*, ii. 8; briefly in *Antiq.*, xviii. 1, 5), we have a sketch of them in Philo (in his treatise *Quod omnis probus liber*, and in the fragment of his *Apology for the Jews* preserved in Eusebius, *Pr. Evang.*, viii. 11), and a brief notice from Pliny (*Hist. Nat.*, v. 17). Josephus himself made trial of the sect of Essenes in his youth; but from his own statement it appears that he must have been a very short time with them, and therefore could not have been initiated into the inner mysteries of the society (*De vita sua*, 2).

There is no little difficulty about their name. Josephus generally writes Ἐσσηνοί, but has Εσσαῖοι sometimes; Philo has Ἐσσαῖοι, and Pliny Esseni. Its derivation is quite uncertain, all the more so as the origin of the sect is totally unknown. The most extraordinary conjecture is that of Philo, who connects it with ὅσιος, holy; Salmasius proposed the Syrian city Essa; Ewald refers it to the "Rabbinical חָזֵי (properly, preserver, guardian), and supposes that the Essenes called themselves so as watchers, servants (of God), since they did not in fact purpose to be anything more than θεραπευταὶ θεοῦ, as Philo says." The most probable root is אסא, to heal, suggested by several authorities, which also is analogous to θεραπευταί, the name of the kindred sect in Egypt. (For a full discussion of the name of the sect, see Canon Lightfoot on the Colossians.)

The Essenes were an exclusive society, distinguished from the rest of the Jewish nation in Palestine by an organization peculiar to themselves, and by a theory of life in which a severe asceticism and a rare benevolence to one another and to mankind in general were the most striking characteristics. They had fixed rules for initiation, a succession of strictly separate grades within the limits of the society, and regulations for the conduct of their daily life even in its minutest details. Their membership could be recruited only from the outside world, as marriage and all intercourse with women were absolutely renounced. They were the first society in the world to condemn slavery both in theory and practice; they enforced and practised the most complete community of goods. They chose their own priests and public office-bearers, and even their own judges. Though their prevailing tendency was practical, and the tenets of the society were kept a profound secret, it is perfectly clear from the concurrent testimony of Philo and Josephus that they cultivated a kind of speculation, which not only accounts for their spiritual asceticism, but indicates a great deviation from the normal development of Judaism, and a profound sympathy with Greek philosophy, and probably also with Oriental ideas. At the same time we do our Jewish authorities no injustice in imputing to them the patriotic tendency to idealize the society, and thus offer to their readers something in Jewish life that would bear comparison at least with similar manifestations of Gentile life.

There is some little difficulty in determining how far the Essenes separated themselves locally from their fellow-countrymen. Josephus informs us that they had no single city of their own, but that many of them dwelt in every city. While in his treatise *Quod omnis*, etc., Philo speaks of their avoiding towns and preferring to live in villages, in his *Apology for the Jews* we find them living in many cities, villages, and in great and prosperous towns. In Pliny they are a perennial colony settled on the western shore of the Dead Sea. On the whole, as Philo and Josephus agree in estimating their number at four thousand, we are justified in suspecting some exaggeration as to the many cities, towns, and villages where they were said to be found. As agriculture was their favorite occupation, and as their tendency was to withdraw from the haunts and ordinary interests of mankind, we may assume that with the growing confusion and corruption of Jewish society, they felt themselves attracted from the mass of the population to the sparsely peopled districts, till they found a congenial settlement and free scope for their peculiar view of life by the shore of the Dead Sea. While their principles were consistent with the neighborhood of men, they were better adapted to a state of seclusion.

The Essenes did not renounce marriage because they denied the validity of the institution or the necessity of it as providing for the continuance of the human race, but because they were convinced of the artfulness and fickleness of the sex. They adopted children when very young, and brought them up on their own principles. Pleasure generally they rejected as evil. They despised riches not less than pleasure; neither poverty nor wealth was observable among them; at initiation every one gave his property into the common stock; every member in receipt of wages handed them over to the funds of the society. In matters of dress the asceticism of the society was very pronounced. They regarded oil as a defilement, even washing it off if anointed with it against their will. They did not change their clothes or their shoes till they were torn in pieces or worn completely away. In general they thought it good to dress coarsely, and preferred to be clad in white. Their daily routine was prescribed for them in the strictest manner. Before the rising of the sun they were to speak of nothing profane, but offered to it certain traditional forms of prayer as if beseeching it to rise. Thereafter they went about their daily tasks, working continuously at whatever trade they knew till the fifth hour, when they assembled, and, girding on a garment of linen, bathed in cold water. They next seated themselves quietly in the dining hall, where the baker set bread in order, and the cook brought each a single dish of one kind of food. Before meat and after it grace was said by a priest. After dinner they resumed work till sunset. In the evening they had supper, in which strangers belonging to the society joined them, if there happened to be any such present. Withal there was no noise or confusion to mar the tranquillity of their intercourse; no one usurped more than his share of the conversation; the stillness of the place oppressed a stranger with a feeling of mysterious awe. This composure of spirit was owing to their perfect temperance in eating and drinking. Not only in the daily routine of the society, but generally, the activity of the members was controlled by their presidents. In only two things could they take the initiative, helpfulness, and mercy; the deserving poor and the desti-

tute were to receive instant relief; but no member could give anything to his relatives without consulting the heads of the society. Their office-bearers were elected. They had also their special courts of justice, which were composed of not less than a hundred members, and their decisions, which were arrived at with extreme care, were irreversible. Oaths were strictly forbidden; their word was stronger than an oath. They were just and temperate in anger, the guardians of good faith, and the ministers of peace, obedient to their elders and to the majority. But the moral characteristics which they most earnestly cultivated and enjoined will best appear in their rules of initiation. There was a novitiate of three years, during which the intending member was tested as to his fitness for entering the society. If the result was satisfactory, he was admitted, but before partaking of the common meal, he was required to swear awful oaths, that he would reverence the deity, do justice to men, hurt no man voluntarily or at the command of another, hate the unjust and assist the just, and that he would render fidelity to all men, but especially to the rulers, seeing that no one rules but of God. He also vowed, if he should bear rule himself, to make no violent use of his power, nor outshine those set under him by superior display, to make it his aim to cherish the truth and unmask liars, to be pure from theft and unjust gain, to conceal nothing from his fellow-members, nor to divulge any of their affairs to other men, even at the risk of death, to transmit their doctrines unchanged, and to keep secret the books of the society and the names of the angels.

Within the limits of the society there were four grades so distinct that if any one touched a member of an inferior grade he was required to cleanse himself by bathing in water; members that had been found guilty of serious crimes were expelled from the society, and could not be received again till reduced to the very last extremity of want or sickness. As the result of the ascetic training of the Essenes, and of their temperate diet, we find that they lived to a great age, and were superior to pain and fear. During the Roman war they cheerfully underwent the most grievous tortures rather than break any of the principles of their faith. In fact, they had in many respects reached the very highest moral elevation attained by the ancient world; they were just, humane, benevolent, and spiritually minded; the sick and aged were the objects of a special affectionate regard; and they condemned slavery, not only as an injustice, but as an impious violation of the natural brotherhood of men. There were some of the Essenes who permitted marriage, but strictly with a view to the preservation of the race; in other respects they agreed with the main body of the society.

It will be apparent that the predominant tendency of the society was practical. Philo tells us expressly that they rejected logic as unnecessary to the acquisition of virtue, and speculation on nature as too lofty for the human intellect. Yet they had views of their own as to God, Providence, the soul, and a future state, which, while they had a practical use, were yet essentially speculative. On the one hand, indeed, they held tenaciously by the traditional Judaisms; blasphemy against their lawgiver was punished with death, the sacred books were preserved and read with great reverence, though not without an allegorical interpretation, and the Sabbath was most scrupulously observed. But in many important points their deviation from the strait path of Judaic development was complete. They rejected animal sacrifice as well as marriage; the oil with which priests and kings were anointed they accounted unclean; and the condemnation of oaths and the community of goods were unmistakable innovations for which they found no hint or warrant in the old Hebrew writings. Their most singular feature, perhaps, was their reverence for the sun. As we have seen, no profane word was to be uttered before his rising, and certain forms of prayer were offered to him; they were not to insult his rays by any act of uncleanness, however natural. In their speculative hints respecting the soul and the future state, we find another important deviation from Judaism, and the explanation of their asceticism. They held that the body is mortal, and its substance transitory; that the soul is immortal, but, coming from the subtlest ether, is lured as by a sorcery of nature into the prison-house of the body. At death it is released from its bonds, as from long slavery, and joyously soars aloft. To the souls of the good there is reserved a life beyond the ocean, and a country oppressed neither by rain, nor snow, nor heat, but refreshed by a gentle west wind blowing continually from the sea, but to the wicked a region of wintry darkness and of unceasing torment. (In these points the resemblance of Essenism to certain phases of Greek philosophy and to some of the earlier Greek myths is unmistakable.) To all intensely earnest minds, in which the force of one great idea is not corrected by other tendencies, a spiritual asceticism is the natural complement of a theory according to which a vile body is the prison-house of an immortal soul. Josephus tells us, too, that the Essenes believed in fate; but in what sense, and what relation it bore to Divine Providence, does not appear.

In view of such divergences from the nominal development of Judaism, and of doctrines on the soul and a future state, which so closely resembles Pythagorean, Platonic, and even Zoroastrian speculations, the question naturally arises how far Essenism was a native product of the Jewish mind, and how far it had experienced the influence of Greek and Oriental thought. On the one hand it is clear, from the facts we have noted, that it must have completely passed the barriers of traditional Judaism, and equally clear, on the other, that the Essenes could not have reached their peculiar point of view in perfect isolation from antecedent and contemporary speculation. For more than a century before the Essenes appear as a factor in Jewish history, the Jews had come into closest contact with Greek life; doubtless they were rather repelled than attracted, but in either case could not help being affected, by it. With the theosophic speculations of Persia they had also been acquainted for many centuries, first during the Babylonian captivity, and afterwards through the general diffusion of that way of thought in the adjoining countries. All this influence had greatly modified the opinions of the Jews. Nations cannot altogether select the medium in which they live, nor resist its influence, however vigorously they cling to an hereditary faith. Whatever they may have acquired in their intercourse with Persia must have already passed into Jewish thought generally, and probably had no special connection with the origin of the Essenes; but may we not assume with Zeller some direct and express influence of the Neo-Pythagoreans as that which gave Essenism its distinctive character? As Josephus himself says, the Essenes live the same kind of life as the Pythagoreans. The Essenes certainly did realize the Pythagorean ideal. In beliefs, institutions, and tendencies we are struck by their close resemblance. It is not impossible they were directly connected. Still the second century before Christ is too early a date to look for such a strong manifestation of Neo-Pythagoreanism on Jewish soil. Besides we have all the data for explaining the origin of the Essenes without supposing any direct influence of the Neo-Pythagorean school. Greek culture was widely diffused among the Jews; the Greek philosophy was accessible to their scholars; Jewish thought could not but obey the impulse of the dominant civilization, and could not avoid more or less completely moving in parallel directions. So much must be conceded as to the medium in which the thoughtful Jewish intellect lived. On the other hand, like causes produce like results in all countries. Certain conditions of civilization have favored the formation of secret societies, with analogous institutions, in all ages. Accordingly, while we cannot fail to perceive a general affinity to Greek and Oriental thought in the tenets and institutions of the Essenes, we see still more clearly the proverbial intensity of the Jews, seeking in an organized seclusion from the world that satisfaction which they could not find in a disturbed and decaying national life. The Jewish people were unhappily hastening to the final catastrophe; misrule, corruption, and fanaticism were everywhere gathering head; good men despaired of controlling such a headlong and turbulent movement; what could they do but withdraw from it, and cultivate a purer life under such conditions as secured or admitted it, in the exclusive society of men like-minded with themselves?

The original sources of our knowledge of the Essenes have been mentioned at the beginning of this paper; the best modern discussions of them are to be found in such works as Zeller's *Philosophie der Griechen*, vol. iii.; Ewald, *Geschichte d. V. Israël*, iii. 419–428; Reuss, *La theologie chrétienne au siècle apostolique*, i. 122–131; Keim, *Life of Jesus of Nazara*, vol. i.; Canon Lightfoot on the Colossians. (T. K.)

Plate VI.

ESSEX, the tenth in size of the English counties, is situated on the S.E. coast, and is consequently bounded on the E. and S.E. by the North Sea. On the S. it is separated from Kent by the river Thames, on the W. from Middlesex and Hertfordshire by the Lea and the Stort, and on the N.E. from Suffolk by the Stour, while on the N. it is conterminous with Cambridgeshire.

Essex contains 1,055,133 acres, or 1648 square miles. The population in 1851 was 369,318; in 1861, 404,834; and in 1871, 466,436 (233,903 males and 232,533 females). The increase is found to be almost entirely in the south-western corner of the county contiguous to the metropolis,—the parish of West Ham, which by the last census contained 62,919 inhabitants, being now estimated to have about 110,000. The coast has an exceedingly irregular outline, and, short as it is, it is deeply indented by estuaries of no less than three rivers—the Stour at Harwich, the Blackwater and Colne at Maldon, and the Thames; and as may be suggested by this fact, the seaboard entirely lacks the bold and rugged beauty of the shores of the west of England. The rivers, with the exception of the Thames, are insignificant; and so far as they are navigable they are useful chiefly for the transport of agricultural produce. Harwich is the only considerable harbor, but Wivenhoe, on the Colne, is celebrated for its yacht-building. The sea has within historic times encroached upon the land; and near Walton, on the Naze, ruins of buildings have been discerned at low water on a shoal known as the West Rocks, five miles out. On the cliffs of Walton are to be found interesting geological remains. In the parish of Dagenham there is a large tract at a lower level than the river, protected by an extensive dyke, which was restored in 1723 at an expense of nearly £42,500.

The Crouch, the Blackwater, and the Colne all supply favorite beds for oyster layers; and lawsuits to determine the right of dredging in these rivers have been pending for years. Barking sends out a large fleet of fishing smacks in the pursuit of turbot, soles, cod, etc.

Geologically, the county rests almost entirely upon the London clay, which has been frequently pierced and found to be of great thickness. At Lamarsh, during the construction of the Stour Valley Railway, parts of a fossil elephant were discovered in a gravel stratum 14 feet below the surface. The soil of the southern and eastern portions is mostly of a rich alluvial character, with occasional traces of gravel; the Roothings in the centre are clay; but the northern district is sound loam, becoming lighter as it approaches Cambridgeshire. The landscape varies in like degree, the flat, uninteresting, but fertile grazing grounds near the coast and rivers providing a strong contrast to the undulating and frequently hilly neighborhoods of Danbury, Baddow, Wickham, Weald, Laindon Hills, Havering, Warley, and Hedingham.

The roads of this county could hardly be surpassed; with a clay soil foundation, they have for generations been repaired with flints, picked by women and children from the surface of the fields,—an industry which will die out under the new Education Acts. Gravel is difficult of access, and some of the inland towns are purchasing granite for their streets; near Good Easter and Chignal, not ten miles from Chelmsford, the road surveyors are driven to the expedient of collecting pebbles from the brooks. With the exception of chalk for lime (mainly obtained at Ballingdon in the north and Grays in the south), septaria for making cement, and clay for bricks, the underground riches of the county are meagre, and it is to agriculture that we must look for the internal resources of Essex.

For the large quantity and the fine quality of both its wheat and its barley Essex has long been famous. Essex wheat is one of the standard quotations of the London markets, and thousands of quarters are exported to the north of England, as well as to France, for seed purposes; the Essex Rough Chaff, the Nursery, the Golden Drop, and the Taunton Dean, all flourish in perfection. What the barley lacks in delicacy of appearance and in fineness of skin, it makes up for in weight and size of berry, and in its kindly nature in malting. Beans are a prolific crop in most parts of the country, and pease, both for harvesting and for picking green for the London market, produce abundantly. The enormous importations from Russia and Sweden have caused farmers to neglect the cultivation of oats, and to turn their attention to the growth of the more lucrative barley; and the acreage of mangel-wurtzel and of kohl-rabi is gradually increasing, to the diminution of the more precarious turnip crop. The system of agriculture has undergone changes so great that the men of two generations ago could scarcely now recognize the face of the country, nor comprehend the routine of the farm. The extravagantly high and wide fences and the cramped little fields have given way to a more intelligent scheme; the antiquated four-course shift is seldom heard of except in covenants controlling the last period of leases; long fallows are abandoned; steam cultivation has become general; the sickle is replaced by the reaping-machine, and other machines are employed to mow the grass, and shake it out, gather it, and even to "cock" it and elevate it to the stacks; in like manner the cereal crops are sown, hoed, reaped, stacked, and thrashed by a force superior to, and cheaper than, manual power; and the employment of women and gangs of children in the fields, once so general, is now the exception. The generous treatment of the land by the farmers of the county has been followed by corresponding concessions on the part of the landowners; and although the recent Agricultural Holdings Act has become nearly a dead letter owing to landlords "contracting themselves out of the Act," yet there is for the most part a mutual good feeling between owner and occupier, and in cases where leases are granted the covenants are practical and liberal. It is probable, however, that in no county in England is the phrase "farming by the custom of the country" so vague and elastic as in Essex; the system which is successful "on the flat" in the district north of Finchingfield and Radwinter would be ruinous or impossible in Dengie Hundred, with its deep furrows drawn by powerful and costly teams between the narrow reaches of Purleigh, Mundon, and Latchingdon; notwithstanding, both districts produce excellent crops. Not the least interesting feature in the agriculture of the county is the rapid disillusion which has taken place with regard to the growth of certain varieties of farm produce, which it was supposed could only be raised on certain soils and in certain districts,—notably the cultivation of root crops and of barley, which now take their place in the ordinary rotation nearly throughout Essex. There are, it is true, localities particularly favorable to certain crops, and at Castle Hedingham, at Sible Hedingham and Coggeshall, and at Feering we find seed-growing practised both for the farm and the garden; at Wethersfield, Shalford, Hedingham, and Bocking are hop-grounds, which are, however, gradually dying out; Tiptree Heath supplies large quantities of fruit, used principally by the London traders for preserving; the teasel and the aromatic seeds, coriander and caraway, have well-nigh disappeared; onions, French beans, cabbages, potatoes, indeed all kinds of vegetables, are produced at Barking, Rainham, Aveley, and the neighborhood, whence they are transferred by road to Covent Garden Market. Agricultural horses are imported from Suffolk, Norfolk, Lincolnshire, and Belgium, comparatively few being bred at home. Several herds of shorthorns have been established, but thousands of store bullocks are introduced from Norfolk, Lincolnshire, Ireland, and Wales; of sheep there are but few distinct flocks; the pig tribe is represented by a high-class Berkshire type,—the "improved Essex," a breed introduced by the late Fisher Hobbs, having become absorbed by frequent crossing. From the comparative dryness of the climate Essex does not excel in pasturage, and in consequence the majority of farmers devote their attention to winter grazing, and fatten their stock upon roots, cut hay, bean-meal, pease-meal, and vast quantities of oilcake, usually of American manufacture. The county possesses one of the largest and most influential agricultural associations in the kingdom, numbering between 800 and 900 members, and giving away from £1500 to £1900 annually in prizes, many of which are open for competition to all England; the chamber of agriculture has 600 subscribers. Attempts at sewage farming have been made in several localities, but in most cases the sewage farm is looked upon as a necessary evil. Many of the minor towns have their sewage farm attached, but the disposal of the drainage usually exhausts any possible remuneration for the excessive outlay.

Essex, which was at one time famous for the extent of its forests, has for many years been decreasing its acreage of woodland. Epping Forest, which is of the estimated extent of 60,000 acres, has been in jeopardy of encroachment, but by the "Epping Forest Act, 1871," a board of commissioners was appointed for the better management of the lands; the corporation of the city of London has acquired by purchase the freehold interest of waste land belonging to the lords of the manor, thus, at an outlay of £50,000, securing 800 acres for the benefit of the public for ever; the

Ancient Court of Verderers has also been revived, and consists of an hereditary lord warden together with four verderers, elected by freeholders of the county. The celebrated Fairlop oak, which measured 45 feet in girth, was blown down in 1820; the largest now standing is only 18 feet in girth. Hainault Forest was disafforested in 1851.

The landowners of Essex number 22,305, of whom 14,833, or 66½ per cent., hold less than one acre each, the proportion for all England being 71 per cent. The gross estimated rental is put at £2,166,077, or £2, 5s. 6¾d. per acre, as compared with £3, 0s. 2¼d. for all England. From the return of 1873 we find that of owners possessing more than 5000 acres each, Lord Petre, Thorndon Hall, owns 19,085 acres; Lord Braybrooke, Audley End, 9684; Executors of Lord Maynard, Easton Lodge, 8617; Lord Rayleigh, Terling Place, 8536; the Governors of Guy's Hospital, 8400; Sir T. C. C. Western, Felix Hall, 7875; R. B. Wingfield Baker, Orsett Hall, 7579; J. Archer Homblon, Great Hallingbury, 7127; J. Jolliffe Tufnel, Langleys, 6582; Mrs. Honywood, Markshall, 6436; Colonel Bramston, Skreens, 6318; Executors of T. G. G. White, Berechurch Hall, 5600; Crown property, 5526; the Governors of the Charter House, 5481; Sir C. Du Cane, Braxted Park, 5409; the Countess Waldegrave, Dudbrook, 5108.

The manufacturing establishments in the county comprise the various iron works at Chelmsford, Colchester, Maldon, Colne, Halstead, and Rayne (which supply agricultural implements for local use), important crape factories at Bocking and Halstead, a large manufactory of rich damasks and satins for furniture at Bocking, and a considerable jute factory at Barking. There are also Government gunpowder mills at Waltham Abbey.

The county forms nineteen "hundreds," each comprising several parishes, and one "liberty," that of Havering-atte-Bower, which includes Hornchurch and Romford. The "liberty" has a special jurisdiction of its own, independent of the county, having its own high steward, magistrates, clerk of the peace, coroner, and quarter sessions for the trial of offences committed within the borders of three parishes.

The principal towns are Colchester (population, 26,343), Chelmsford (9318), Maldon (population of parliamentary borough, 7151), Romford (6335), Harwich (6079), Halstead (5783), Barking (5766), Saffron Walden (5718), Braintree (4790), Witham (3347), Dunmow (3342). For parliamentary purposes the county is divided into three constituencies, east, south, and west, each returning two members; the borough of Colchester also sends two representatives to the House of Commons, while Maldon and Harwich elect one each, making a total of ten members. There are 250 justices of the peace for the county, which is divided into 18 petty sessional divisions. There are 17 poor law unions, 10 local boards of health, and 62 school boards. A large camp at Colchester, usually containing 3000 infantry and 1000 artillery and cavalry, is the headquarters of the eastern district of England, Great Warley being the military centre for Essex. Two regiments of militia are established, the Essex rifles and the West Essex regiment, having their headquarters at Colchester and at Chelmsford respectively.

According to the recent alterations in the arrangement of the circuits, Essex, Herts, Suffolk, Norfolk, Cambridgeshire, and Huntingdonshire are included in the south-eastern circuit, formed by the amalgamation of the home circuit with a portion of the Norfolk circuit. Ecclesiastically Essex belongs to the new diocese of St. Albans, instead of Rochester, as formerly. The new see, which also embraces Herts, has a population of 659,152, and an area of 2268 square miles. The county lunatic asylum is situated between Brentwood and Warley barracks; there is an infant orphan asylum at Wanstead, and a seaman's orphan asylum at Snaresbrooke.

Essex is comparatively poor in prehistoric remains, but for this it is richly compensated by the variety and value of its Roman and mediæval antiquities. The so-called Dane-pits not improbably belong to the pre-Roman period: they are almost certainly shafts sunk for chalk, and we know that at a very early date this material was exported from Britain to the Continent. By some antiquaries Lexden is regarded as the site of the *British* town of Camulodunum, and certain mounds are identified with its defences. We know from history that within the present boundaries of Essex the Romans had not only their great central post of Camulodunum, but also stations called Durolitum, Cæsaromagus, Canonum, Iceanum, and Othona. The site of several of these, however, is still matter of debate. Durolitum was possibly at or near Romford, no Roman remains having been found at Layton, which was once selected from a very superficial similarity of name; Cæsaromagus is usually identified with Chelmsford, and Iceanum with Chesterford; and there is little or no doubt that Othona, the Ithanceaster of Bede, was situated near Bradwell. Roman military works have been recognized at Danbury, Tilbury, Harwich, Pleshy, etc., Roman dwelling-houses discovered at Chelmsford, at Sunken Church Field, near Hadstock, at Ridgewell, etc., and Roman cemeteries or tombs at Chelmsford, Chesterford, Hadstock, Bartlow, Coggeshall, and Wormingfield. At Wormingfield alone hundreds of urns have been exhumed. Large quantities of Roman ware have turned up at Stifford and Canvey Island; and Hallingbury church is far from the only building that has been indebted to the Roman brickmakers. Of Roman works of art discovered in the county perhaps the most remarkable are the Colchester Sphinx and an effigy of a centurion unearthed in the same city. A Roman road connected London with Camulodunum, and another ran from Camulodunum to Cambridge, and sent off a branch to St. Albans. It is supposed by many antiquaries that Saxon masonry can be detected in the foundations of several of the Essex churches, but, with the exception of Ashingdon church tower, believed to have been erected by Canute after his victory over Edmund Ironside, there is certainly no very recognizable building belonging to that period. This is probably to be in part ascribed to the fact that the comparative scarcity of stone and the unusual abundance of timber led to the extensive employment of the latter material. Many of the Essex churches, as Blackmore, Mountnessing, Margaretting, and South Bemfleet, have still massive porches and towers of timber; and St. Andrew's church, Greenstead, with its walls of solid oak, continues an almost unique example of its kind. Of the four "round churches" in England one is in Essex at Little Maplestead; but it is both the smallest and the most modern. The churches of South Weald, Hadleigh, Blackmore, Heybridge, and Hadstock may be mentioned as containing Norman masonry; Southchurch, Danbury, and Boreham as being partly Early English; Ingatestone, Stebbing, and Tilty for specimens of decorated architecture; and Messing, Thaxted, and Saffron Walden as specimens of the Perpendicular. Stained glass windows have left their traces in several of the churches, the finest remains being those of Margaretting, which represent a tree of Jesse and the daisy or herb Margaret. Paintings have evidently been largely used for internal decoration: a remarkable series, probably of the 12th century, but much restored in the 14th, exists in the chancel of Copford Church; and in the Church at Ingatestone there was discovered in 1868 an almost unique fresco representation of the seven deadly sins. The oldest brasses preserved in the county are those of Sir William Fitz-Ralph at Pebmarsh, about 1323; Richard of Beltown, at Corringham, 1340; Sir John Gifford, at Bowers Gifford, 1348; Ralph de Kneyton, at Aveley, 1370; Robert de Swynbourne, at Little Horkesley, 1391; and Sir Ingelram de Bruyn, at South Ockendon, 1400. The brass of Thomas Heron, aged 14, at Little Ilford, though dating only from 1517, is of interest as a picture of a schoolboy of the period. Ancient wooden effigies are preserved at Danbury, Little Leighs, and Little Horkesley.

Essex was rich in monastic foundations, though the greater number have left but meagre ruins behind. The Benedictines had an abbey at Saffron Walden, nunneries at Barking and Wickes, and priories at Monk's Colne and Hedingham; the Augustinian canons had an abbey at Waltham (see WALTHAM ABBEY), priories at Thoby, Blackmore, Bicknacre, Little Leighs, Little Dunmow, and St. Osyth; there were Cistercian abbeys at Coggeshall, Stratford, and Tilty; the Cluniac monks were settled at Prittlewell, the Premonstratensians at Beleigh Abbey, and the Knights Hospitallers at Little Maplestead. Barking Abbey is said to date its first origin from the 7th century; the most of the others arose in the 12th and 13th centuries. Besides the keep at Colchester there is a fine Norman castle at Hedingham, and two dilapidated round towers still stand at Hadleigh. Ongar, the house of the De Lacys, and Pleshy, the seat of the earls of Essex, have left only mounds behind them. Havering, the palace that was occupied by so many of our queens, is replaced by a modern house; Wickham, the mansion of the bishops of London, is no more; and Theobald's Park, the splendid creation of Lord Burleigh, has shared the same fate. New Hall, which was successively occupied by Henry VIII., Elizabeth, the earl of Essex, George Villiers duke of Buckingham, and Cromwell, is now a nunnery of the order of the Holy Sepulchre. Audley End, the mansion of Lord Braybrook, whose name is so well known in connection with Essex antiquities, is a noble example of the domestic architecture of the Jacobean period; Layer Marney is an interesting proof of the Italian influences that were at work in the time of Wolsey. Horeham Hall was built by Sir John Cutt in the reign of Henry VII., and Gosfield Hall is of about the same date.

Its position in the south-eastern corner of England, and its contiguity to the metropolis, have given Essex no small prominence in the general history of England. The Romans of the first invasion (55 B.C.) received the nominal submission of its British inhabitants, the Trinobantes, who also occupied portions of what are now Middlesex, Suffolk, Hertfordshire, and Cambridge. We have numismatic evidence of no inconsiderable civilization among this tribe in the following generation: Cunobelin or Cymbeline is well known from his coins, and his son Caractacus is the great hero of the national defence against the second Roman invasion. The defence, as is well known, was futile: Camulodunum, the Trinobantian capital, was captured; and Aulus Plautius made it the seat of a magnificent temple to the honor of Claudius the emperor. During the great Boadicean rebellion, the Romans were driven from their post with terrible slaughter, but they soon recovered their ground and rapidly colonized the country. How thoroughly they took root can be read to this day in the relics they have left. When the Saxons from over the sea began to make raids on the decadent colony, Essex formed part of the domain of the count of the Saxon Shore; and not long after the withdrawal of the Roman forces it was occupied by the men whose name it still bears, the East Seaxa or East Saxons. Their separate dynasty continued till about 823, when they were incorporated with the rising power of Wessex, which was destined to widen into England. By the peace of Wedmore, Essex was recognized by Alfred as part of the Danish territory of Guthrum, but the Danes were expelled by Alfred's son, Edward the Elder. They have probably left a few traces of their presence in such names as Danbury and Dane-holes; but there is hardly a *by* to be met with among the numerous Saxon *fords*, *wealds*, *hams*, *thorps*, *burys*, and *ings*. The futile attempt of Mellitus left the Christianization of the East Saxons to Cedd, who is said to have formed churches at Tilbury and Ithanceastre in the latter part of the 7th century. In 991 a great battle was fought at Maldon against the Danes, made memorable for ever to Englishmen by a Saxon song which celebrates the valor of Brihtnoth and his peers; and it was probably at Ashington on the Crouch that in 1016 Cnut and Edmund Ironside met in what the early chroniclers call the battle of Assandun. In 1045 Essex was part of the earldom of Harold. The family of Swene of Essex, who was in possession of a large part of the county at the time of the Conquest, kept its ground for nearly a century. A new earldom created by Stephen was held by the Mandevilles till 1227, passed by marriage to the Bohuns, and went with the daughter of Humphrey de Bohun to Thomas of Woodstock, son of Edward III. Through his daughter it passed to William Bourchier, but the male line failed in 1540. The earldom was next assigned to Thomas Cromwell and William Parr, and from 1571 to 1646 it was held by the family of Devereux. Two years after the death of the last earl, who had joined the Parliamentary party, the city of Colchester was besieged and captured by the Parliamentary forces; and throughout the struggle the people of Essex were mainly on the popular side. After the Restoration, Arthur Capel was created Earl of Essex, and that family is still in possession of the title. Of the celebrities of Essex it is sufficient to mention Samuel Purchas, Joseph Mead, John Ray, Joseph Strutt, Philemon Holland, Dr. William Gilbert, Thomas Tusser, Francis Quarles, Thomas Gainsborough, and Dick Turpin.

Scott, *Dunmow Parish Antiquities*, 1873; J. G. Watson, *The tendering Hundred in the olden time*, 1877; and the *Transactions of the Essex Arch. Soc.* from the year 1858. An account of various MS. collections connected with the county is given by H. W. King in vol. ii. of the *Transactions*, 1863. (C. P. W.)

ESSEX, Walter Devereux, first Earl of (1540–1576), in the Devereux line, the eldest son of Sir Richard Devereux, was born in 1540. He succeeded his grandfather as Viscount Hereford in 1558, and in 1561 or 1562 he married Lettice, daughter of Sir Francis Knollys. In 1569 he served as high marshal of the field under the earl of Warwick and Lord Clinton, and materially assisted them in suppressing the northern insurrection. For his zeal in the service of the queen on this and other occasions, he in 1572 received the garter and was created Earl of Essex, a title which formerly belonged to his family through marriage with the Mandevilles. His honors had been merited more by good intentions than by actual achievements; and eager to give proof of "his good devotion to employ himself in the service of her Majesty," he offered on certain conditions to subdue and colonize, at his own expense, a portion of the Irish province of Ulster, at that time completely under the dominion of rebel chiefs. His offer, with certain modifications, was accepted, and he set sail for Ireland in August, 1573, accompanied by a number of earls, knights, and gentlemen, and with a force of about 1200 men. The beginning of his enterprise was inauspicious, for on account of a storm which dispersed his fleet and drove some of his vessels as far as Cork and the Isle of Man, his forces did not all reach the place of rendezvous till late in the autumn, and he was compelled to entrench himself at Belfast for the winter. Here, by sickness, famine, and desertions, his troops were diminished to little more than 200 men, and he almost determined to abandon his undertaking; but receiving in the spring a reinforcement, he compelled the sumission of Sir Brian MacPhelim, massacred by stratagem 200 of the O'Neals, taking Sir Brian O'Neal prisoner, and induced the earl of Desmond to surrender himself to the deputy Fitzwilliam. Elizabeth, however, instigated most probably by Leicester, after encouraging Essex to prepare to invade Trilogh Lenogh, suddenly commanded him to "break off his enterprise;" but as she left him a certain discretionary power, he took advantage of it to defeat Trilogh Lenogh, chastise Antrim, and massacre several hundreds of persons, chiefly women and children, discovered hiding in the caves of Rathlin. He returned to England in the end of 1575, resolved "to live henceforth an untroubled life;" but he was ultimately persuaded to accept the offer of the queen to make him earl marshal of Ireland. He arrived in Dublin in September, 1576, and three weeks afterwards died of dysentery. There were suspicions that he had been poisoned by Leicester, who shortly after his death married his widow, but these were not confirmed by the *post mortem* examination. The endeavors of Essex to better the condition of Ireland were, it must be admitted, a dismal failure; and the massacres of the O'Neals and of the Scots of Rathlin leave a somewhat dark strain on his reputation. But in judging of his achievements, it must be remembered that the problem which he had undertaken to solve was exceptionally difficult, that his own energetic efforts were constantly thwarted by the jealousy of Fitzwilliam and the vacillations of Elizabeth, and that he died before his abilities could be sufficiently tested; and in estimating his character we must set over against his acts of cruelty, which the opinion of the time approved, his honesty and uprightness, and the noble generosity with which he devoted his life and fortune to the performance of a thankless task.

See *Lives of the Devereux Earls of Essex*, by the Honorable Walter Bourchier Devereux (1853), and Froude's *History of England*, vol. x.

ESSEX, Robert Devereux, Second Earl of (1567–1601), son of the preceding, was born at Netherwood, Herefordshire, November 10, 1567. He entered the university of Cambridge in 1577, and graduated in 1581. He appeared at court in 1584. In 1585 he accompanied the earl of Leicester on an expedition to Holland, and greatly distinguished himself at the battle of Zutphen. In 1587 he was appointed master of the horse, and in the following year was made general of the horse, and installed knight of the garter. On the death of Leicester he succeeded him as chief favorite of the queen, a position which injuriously affected his whole subsequent life, and ultimately resulted in his ruin. While Elizabeth was approaching the mature age of sixty, Essex was scarcely twenty-one. Though well aware of the advantages of his position, and somewhat vain of the queen's favor, his constant attendance on her at court was irksome to him beyond all endurance; and when he could not make his escape to the scenes of foreign adventure after which he longed, he varied the monotony of his life at court by intrigues with the maids of honor. In 1589, without the queen's consent, he joined the expedition of Drake and Norreys against Portugal, but on the 4th June was compelled to obey a letter enjoining him at his "uttermost peril" to return immediately. Soon after his return occurred his famous duel with Sir Charles Blount, a rival favorite of the queen, in which the earl was disarmed and slightly wounded in the thigh. In 1590 Essex married the widow of Sir Philip Sidney, but in dread of the queen's anger he kept the marriage secret as long as possible. When it was necessary to avow it, her rage at first knew no bounds, but as the earl did "use it with good temper," and "for her majesty's better satisfaction was pleased that my lady should live retired in her mother's house," he soon came to be "in very good favor." In 1591 he was appointed to the command of a force auxiliary to one formerly sent to assist Henry IV. of France against the Spaniards; but after a fruitless campaign he was finally recalled from the command in January, 1592. For some years after this, most of his time was spent at court, where he held a position of unexampled influence, both on account of the favor of the queen, and from his own personal popularity. In 1596 he was, after a great many "changes of humor" on the queen's part, appointed along with Lord Charles Howard to the command of an expedition, which was successful in defeating the Spanish fleet, capturing and pillaging Cadiz, and destroying 53 merchant vessels. It would seem to have been shortly after this exploit that the beginnings of a change in the feelings of the queen towards him came into existence. On his return she chided him that he had not followed up his successes, and though she professed great pleasure at again seeing him in safety, and was ultimately satisfied that the abrupt termination of the expedition was contrary to his advice and remonstrances, she forbade him to publish anything in justification of his conduct. She doubtless was offended at his growing tendency to assert his independence, and jealous of his increasing popularity with the people; but it is also probable that her strange infatuation regarding her own charms, great as it was, scarcely prevented her from suspecting either that his professed attachment had all along been somewhat alloyed with considerations of personal interest, or that at least it was now beginning to cool. Francis Bacon, at that time his most intimate friend, endeavored to prevent the threatened rupture by writing him a long letter of advice; and although perseverance in a long course of feigned action was for Essex impossible, he for some time attended pretty closely to the hints of his mentor, so that the queen "used him most graciously." In 1597 he was appointed master of the ordnance, and in the following year he obtained command of an expedition against Spain. He gained some trifling successes, but as the Plate fleet escaped him he failed of his main purpose; and when on his return the queen met him with the usual reproaches, he retired to his home at Wanstead. This was not what Elizabeth desired, and although she about this time conferred on Lord Howard the earldom of Nottingham for services at Cadiz, the main merit of which was justly claimed by Essex, she ultimately held out to the latter the olive branch of peace, and condescended to soothe his wounded honor by creating him earl marshal of England. That nevertheless the irritated feelings neither of Essex nor of the queen were completely healed was manifested shortly afterwards in a manner which set propriety completely at defiance. In a discussion on the appointment of a lord deputy to Ireland, Essex, on account of some taunting words of Elizabeth, turned his back upon her with a gesture indicative not only of anger but of contempt, and when she, unable to control her indignation, slapped him on the face, he left her presence swearing that such an insult he would not have endured even from Henry VIII. In 1599, while Ulster was in rebellion, the office of lord deputy was conferred on Essex, but whether at his own express wish, or only after he was persuaded against his will to accept it, has been disputed. This point has an important bearing on the further question of the origin of Essex's treacherous designs. His campaign was an unsuccessful one, and by acting in various ways in opposition to the commands of the queen and the council, and suddenly leaving the post of duty with the object of privately vindicating himself before the queen, he laid himself open to charges more serious than that of mere incompetency. For these misdemeanors he was deprived of all his high offices, and ordered to live a prisoner in his own house during the queen's pleasure. Chiefly through the intercession of Bacon his liberty was shortly afterwards restored to him, but he was ordered not to return to court. For some time he hoped for an improvement in his prospects, but when he was refused the renewal of his patent for sweet wines, hope was succeeded by despair, and half maddened by wounded vanity, he made an attempt to incite a revolution in his behalf, by parading the streets of London with 300 retainers, and shouting, "For the queen! a plot is laid for my life!" These proceedings awakened, however, scarcely any other feelings than mild perplexity and wonder; and finding that hope of assistance from the citizens was vain, he returned to Essex House, where after defending himself for a short time he surrendered. After a trial—in which Bacon, who prosecuted, delivered a speech against his *quondam* friend and benefactor, the bitterness of which was quite unnecessary to secure a conviction entailing at least very severe punishment—he was condemned to death, and notwithstanding many alterations in Elizabeth's mood, the sentence was carried out 21st February, 1601.

Essex was in person tall and well proportioned, with a countenance which, though not strictly handsome, possessed, on account of its bold, cheerful and amiable expression, a wonderful power of fascination. His carriage was not very graceful, but his manners are said to have been "courtly, grave, and exceedingly comely." He was brave, chivalrous, impulsive, imperious sometimes with his equals, but generous to all his dependants and incapable of secret malice; and these virtues, which were innate and which remained with him to the last, must be regarded as somewhat counterbalancing, in our estimation of him, the follies and vices created by temptations which were exceptionally strong, and which obtained additional power from the time and manner of their occurrence. He was one of the most learned noblemen of his time, and his abilities were considerable and many-sided, but a fatal want of prudence and self-government made him almost the necessary victim of the difficult position in which from his early manhood he had been placed, partly by circumstances, and partly by his own pardonable vanity.

Camden's *Life of Elizabeth; Secret History of Queen Elizabeth and the Earl of Essex*, by a "Person of Quality," pub. at Cologne, 1690, and afterwards at London; Devereux, *Lives of the Earls of Essex;* and *Bacon and Essex*, by Edwin E. Abbott, D.D., 1877. See also the article BACON. (T. F. H.)

ESSEX, ROBERT DEVEREUX, THIRD EARL OF (1591–1646), the son of the preceding, was born in 1591. He was educated at Eton and at Merton College, Oxford. Shortly after the arrival of James I. in London, Essex was placed about the prince of Wales, as a sharer both in his studies and amusements. At the early age of fifteen he was married to Frances Howard, daughter of the earl of Suffolk, but on account of the latter's connection with Rochester (afterwards earl of Somerset), the marriage was annulled in 1613. A second marriage which he contracted in 1629 or 1630 with Elizabeth, daughter of Sir William Paulet, also ended unhappily. From 1620 to 1623 he served in the wars of the Palatinate, and in 1625 he was vice-admiral of a fleet which made an unsuccessful attempt to capture Cadiz. In 1639 he was lieutenant-general of an army sent by Charles against the Scotch Covenanters; but on account of the irresolution of the king no battle occurred, and the army was disbanded at the end of the year. Essex was discharged "without ordinary ceremony," and refused an office which at that time fell vacant, "all which," says Clarendon, "wrought very much upon his rough, proud nature, and made him susceptible of some impressions afterwards which otherwise would not have found such easy admission." Having taken the side of the Parliament against Charles, he was, on the outbreak of the civil war in 1642, appointed to the command of the Parliamentary army. At the battle of Edgehill he remained master of the field, and in 1643 he captured Reading, and relieved Gloucester; but in the campaign of the following year, on account of his hesitation to fight against the king in person, nearly his whole army fell into the hands of Charles. In 1645, on the passing of the self-denying ordinance, providing that no member of Parliament should hold a public office, he resigned his commission; but on account of his past services his annuity of £10,000 was continued to him for life. He died 4th September, 1646, of a fever brought on by over-exertion in a stag-hunt in Windsor Forest.

Life of Robert Earl of Essex, by Robert Codrington, M.A., printed in *Hart. Misc.;* Clarendon's *History of the Rebellion;* and Devereux, *Lives of the Earls of Essex.*

ESSLINGEN, a town of Würtemberg, circle of the Neckar, is situated on the river of the same name, and on the railway from Stuttgart to Ulm, 9 miles N.E. of Stuttgart. It is surrounded by walls, and has five suburbs, one of which is on an island in the river. On a commanding height above the town stands an old castle. The church of Our Lady is a fine Gothic edifice, built in the middle of the 15th century, and has a beautifully sculptured doorway and a tower 230 feet high. The church of St. Dionysius dates from the 11th century, and possesses a fine screen and ciborium of 1486. The town hall is a handsome building. Esslingen has a richly-endowed hospital, an orphan asylum, and a normal and other schools; and near the town there is a hydropathic establishment for the relief of the insane. The manufactures include woollen and cotton stuffs, hardware, and machinery. Esslingen was founded about the 8th century, became a free imperial city in 1209, and in 1801 was annexed to Würtemberg. The population in 1875 was 19.602.

ESTAING, Charles Hector, Comte d' (1729–1794), a French admiral, was born at the château of Ruvel, Auvergne, in 1729. He entered the army as a colonel of infantry, and in 1757 he accompanied Count de Lally to the East Indies, with the rank of brigadier-general. In 1759 he was made prisoner at the siege of Madras, but was released on parole. Before the ratification of his exchange he obtained command of some vessels, and conducted various naval attacks against the English; and having, on his return to France in 1760, fallen accidentally into their hands, he was, on the ground of having broken his parole, thrown into prison at Portsmouth, but as the charge could not be properly substantiated he was soon afterwards released. In 1763 he was named lieutenant-general in the navy, and in 1777 vice-admiral; and in 1778 he obtained the command of a fleet intended to assist the United States against Great Britain. In concert with the American generals, he planned an attack on Newport, preparatory to which he compelled the British to destroy some war vessels that were in the harbor; but before the concerted attack could take place, he put to sea against the English fleet, under Lord Howe, when owing to a violent storm, which arose suddenly and compelled the two fleets to separate before engaging in battle, many of his vessels were so shattered that he found it necessary to put into Boston for repairs. He then sailed to the West Indies, where he captured St. Vincent and Grenada, and compelled the English fleet to take refuge in the harbor of St. Christopher. Despairing of the English leaving their place of refuge, he set sail to attack Savannah, but all his attempts, as well as those of the Americans, against the town, were repulsed with heavy loss, and he was finally compelled to retire. He returned to France in 1780. He was in command of the combined fleet before Cadiz when the peace was signed in 1783; but from that time his chief attention was devoted to politics. In 1787 he was elected to the assembly of the notables; in 1789 he was appointed commandant of the national guard; and in 1792 he was chosen admiral by the national assembly. Though in favor of national reform he continued to cherish a strong feeling of loyalty to the royal family, and on the trial of Marie Antoinette in 1793 bore testimony in her favor. On this account, and because of certain friendly letters which had passed between him and the queen, he was himself brought to trial, and was executed April 28, 1794.

ESTATE, in English law, has many meanings, the common element of which is property. A man's entire belongings constitute his estate: so much of it as consists of land and certain other interests associated therewith is his Real Estate; the rest is his Personal Estate. The legal incidents which distinguish the one from the other may be ascertained by reference to these headings. The word is more particularly applied to interests in land, and in popular and general use an estate means the land itself. The strict technical meaning of an estate is an interest in lands, and this conception lies at the root of the English theory of property in land. "The first thing that the student has to do," says Mr. Joshua Williams (*Law of Real Property*, p. 17), "is to get rid of the idea of absolute ownership. Such an idea is quite unknown to the English law. No man is in law the absolute owner of lands. He can only hold an estate in them." Thus he may hold an estate in fee simple, which is the largest estate a man can hold in English law, and comes close to the idea of absolute ownership, repudiated by Mr. Williams; or he may hold an estate tail, in which the land is limited to himself and the heirs of his body; or he may hold an estate for life, which lasts just so long as the life in question lasts. In all these cases the notion of tenure, of holding by a tenant from a lord, prevails. The last lord of all from whom all land is ultimately held is the king. Persons holding directly from the king and granting to others are the king's tenants *in capite*, and are the mesne lords of their tenants. Even in the case of a fee simple estate, which a man can alienate as he pleases during his life or by his will, and which goes to his heirs if he does not alienate it, the reversionary right of the lord still remains, and may actually come into operation in the case of an Escheat (*q.v.*). For the special characteristics of different estates or land, see Real Estate.

ESTATES OF THE REALM. The proper meaning of this phrase, as applied to the English constitution, has been the subject of some dispute. Of its original meaning there can be no doubt. It indicated a division of society into classes or orders, and in England these orders were the nobles, the clergy, and the commons. The same kind of division is found in Continental states. In England there are, as Professor Stubbs has pointed out (*Constitutional History of England*, vol. ii. p. 189), indications of a tendency on the part of other orders of men to assume the character of estates. For example, the king used to treat with the merchants for grants of money to be raised by taxation from the general body of merchants throughout the country. In this sense the lawyers may be said to have been at one time an incipient estate of the realm. The organization of parliament checked all such tendencies, and the technical "three estates" were those we have mentioned. In the lapse of time the original meaning of the phrase has been gradually lost sight of. The clergy have ceased to be a separate order so far as the political organization of the country is concerned. The "three estates" came to be identified with the three great divisions of the legislative authority,—kings, lords, and commons. The phrase seems to have been used in this sense in the reign of Henry IV., and Hallam says it was a current doctrine among the popular lawyers of the 17th century. According to another view, the three estates of the realm were "the lords spiritual, the lords temporal, and the commons." (See p. 282 of the present volume.)

ESTE, the ancient *Ateste*, a town of Lombardy, in the delegation of Padua, and 18 miles S.S.W. of the town of that name, is beautifully situated at the southern extremity of the Euganean hills, on the canal of Monselice. It has a very antique and picturesque appearance; its houses are mostly of mediæval date; and it possesses some ancient buildings of considerable interest. Chief of these is the *Rocca* or castle, a donjon tower with embrasures and battlements occupying the site of the original fortress of Este. The church of San Martino is of great antiquity, and has a leaning Romanesque campanile. The interior of the church has been modernized. Este also possesses a belfry tower containing a clock made by the celebrated Dondi. The chief manufactures of the town are silk-twist, hats, earthenware, majolica, and saltpetre. Este, under the name of Ateste, existed as early as 136 B.C. In 452 it was destroyed by Attila; and afterwards it was rebuilt by the Lombards within a narrower area. The population in 1871 was 5743.

ESTE, one of the oldest princely houses of Italy. Their genealogy, according to Muratori, can be traced back to the small princes who governed Tuscany under the Carlovingians, and who some time afterwards received certain districts or counties from them in fief. They are in all probability of Longobard origin, but there is no authentic record of their succession reaching farther back than to the marquis Adalbert who died about 917. They were called Este after the town of that name, and the title marquis of Este was first borne by ALBERT AZZO II., who married Kunitza or Kunigonda, sister of Welph or Guelph III., duke of Carinthia. Welph died without issue, and the eldest son of Kunitza, Welph IV., succeeded to his inheritance, and marrying a daughter of Otho II., duke of Bavaria, was created duke of Bavaria, on Otho's death without male succession, in 1071. Through him the house of Este thus became connected with the princely houses of Brunswick and Hanover, from which are descended the sovereigns of England. The Italian title and estates were inherited by FULCO I. (1060–1135), son of Albert Azzo II. by his second marriage to Garisenda, countess of Maine, in France. Hugo, the second son by this marriage, inherited his mother's property in France, but as he died without issue, it ultimately came into the possession of Fulco and his successors. During the 12th, 13th, and 14th centuries, the history of the Estensi is interwoven with that of the other princely houses of northern Italy, of the struggles for supremacy between pope and emperor, of the contests between rival cities, and even of the factions into which individual cities were sometimes divided. From the rivalry between the German Welphs and Weiblungen the names Guelfs and Ghibelines came to be used to designate the two great rival Italian parties; and, as the head of the Guelf party, the Estensi received at different periods the sovereignties of Ferrara, Modena, and Reggio. They distinguished themselves also as the patrons of literature and the fine arts, and had intimate relations with Ariosto and Tasso.

OBIZZO I., son of Fulco I., entered into a league against Frederick Barbarossa, and was comprehended in the Venetian treaty of 1177 by which municipal podestas were instituted. He was elected podesta of Padua in 1182; and in 1184 Frederick named him marquis of Milan and Genoa, a dignity somewhat similar to that of imperial vicar. By carrying off Marchesella, heiress of the Adelardi family of Ferrara, and marrying her to his son Azzo V., he obtained for his family a predominant influence in that city also, but kindled a strife with the family of Torello which continued to rage for two centuries. Obizzo I. died about 1190; and Azzo V. died about eleven years later and was succeeded by Azzo VI. (1170–1212), who became the head of the Guelf party. During the whole lifetime of Azzo VI. a civil war raged almost uninterruptedly in the streets of Ferrara, each party, it is said, being ten times driven from the city. Azzo died in November, 1212, and was succeeded by ALDOVRANDINO, who in 1213 concluded a treaty with Salinguerra Torello, by which the government of Ferrara was divided between them. He died in 1215, and was succeeded by his brother Azzo VII. (1205–1264), surnamed *Novello* or the *Young*. Between him and Eccelino III. de Romano, who leagued himself with the Torelli, a war broke out in 1229, and although a temporary reconciliation was effected in 1233, and Azzo was affianced to Adelaide, niece of Eccelino, it was renewed after his marriage in 1235. At first Eccelino, who supported the cause of Frederick II., was completely victorious in Lombardy, but the influence of Pope Alexander VI. gradually helped to combine the towns of Lombardy against him, and Azzo also received the assistance of many fugitives whom the tyranny of Eccelino had driven from Padua and Verona. Finally, after two years' indecisive skirmishing, Eccelino accepted battle at Cassano, 16th September, 1259, and was completely defeated and taken prisoner, surviving his overthrow only a few days. Azzo died 17th February, 1264, and was succeeded by OBIZZO II. (1240–1293), who in 1288 received the lordship of Modena, and in 1290 that of Reggio. Obizzo was succeeded by his son Azzo VIII., who was elected perpetual sovereign of Modena and Reggio. The two brothers of Azzo, however, laid claim the one to Modena and the other to Reggio, and succeeded in capturing from him both towns. He was also driven from Este, but an attempt to deprive him of Ferrara was unsuccessful. Azzo died 31st January, 1308. He had no legitimate children, and, on account of the hostility towards him of his two brothers, he named as his successor his grandson Fulco III., by his illegitimate son Francis, but despairing of holding possession of Ferrara against the brothers of Azzo, Francis, acting for his infant son, ceded it to the Venetians in lieu of an annual payment, and retired with Fulco to Venice, where they died in obscurity.

After this the possession of Ferrara, Modena, Reggio, and their dependencies was disputed for some years with varying results by the Venetians, the pope, and rival members of the legitimate line of Estensi, but from the time of Azzo VIII. the Estensi annals are intricate, confused, and of little interest until NICHOLAS III. (1384–1441), who exercised sovereignty over Ferrara, Modena, Parma, and Reggio, was declared by Boniface IX. captain-general of the army of the church, and enjoyed in his later years the intimate friendship of the duke of Milan. He died suddenly from poison, most probably administered by his enemies at the court of Milan to prevent his being named the duke's successor. To him succeeded LIONEL, who died in 1450, and was succeeded by BORSO, who was created duke of Modena and Reggio by Frederick III., and, by the pope, duke of Ferrara. Borso was a great patron of literature, and established a printing-press at Ferrara. He died in 1471, and was succeeded by his brother HERCULES I. (1443–1505), who, with the help of the Venetians, seized the sovereignty of Ferrara from Nicholas, the son of Lionel, and afterwards, with the help of Ferdinand king of Naples, retained it against the Venetians and Pope Sixtus IV. The last twenty-five years of his reign were peaceful and prosperous, and his capital became noted both for its luxury and as the resort of men eminent in literature and art. Count Boiardo the poet was his minister, and Ariosto also obtained his patronage and friendship. To Hercules succeeded ALPHONSO I. (1486–1534), who was married to Lucretia Borgia, daughter of Pope Alexander VI. During nearly the whole of his reign Alphonso was engaged in the Italian wars, and in his complicated and difficult position manifested so much energy and adroitness, and such skill as a general, that for a long time he was almost uniformly successful in his enterprises. On the formation in 1508 of the league of Cambray against the republic of Venice he was appointed by Pope Julius II. to the supreme command of the papal troops; but after the Venetians had sustained a considerable number of reverses they made peace with the pope, and agreed to join him against the French. Alphonso was invited to co-operate with the new alliance, and on his refusal war was declared against him; but although he at first lost Modena and Reggio, he subsequently inflicted a succession of defeats on the papal troops. He was, however, desirous of peace, and had gone to Rome with the purpose of making submission to the Pope, when the news that orders had been given for his arrest reached him in time only to enable him to make his escape. On the defeat of the French by the combined arms of Charles V. and Pope Leo X., the possessions of Alphonso were confiscated, but after the death of Leo he was reinstated in them by Charles V. He died on the 31st October, 1534, and was succeeded by his son HERCULES II. (1508–1559), who married Renée daughter of Louis XII. of France, and, joining the league of Henry II. of France and Pope Paul IV. against Spain, was named lieutenant-general of the French army in Italy, and general of the army of the church. The war was, however, prosecuted with little vigor, and peace was made with Spain in 1558. Hercules and his brother Cardinal Hippolytus the younger, were patrons of literature and art, and the latter built the splendid castle of Este. Hercules II. was succeeded by ALPHONSO II., well known on account of his imprisonment of the poet Tasso. Alphonso died in 1597 without issue, and bequeathed his estate to his cousin CÆSAR (1562–1628), but Pope Clement VIII. laid claim to Ferrara, and by a treaty with Lucretia, sister of Alphonso, it was given up to the see of Rome. Cæsar held Modena and Reggio, but with him the splendor of the house of Este began to fade, and from that time it plays only a very subordinate part in Italian history.

The subsequent heads of the Este family were ALPHONSO III., who retired in 1629 to a monastery in the Tyrol, where he ended his days in 1644; FRANCIS I. (1610–1658), who was general of the French army in Italy; ALPHONSO IV. (1634–1662), the father of Mary, the queen of James II. of England, who held a position in the French army during the Spanish war, and by whom was founded the gallery of pictures at Modena; FRANCIS II. (1660–1694), who originated the library of Este and founded the University of Modena; Rinaldo (1665–1737), through whose marriage with Charlotte Felicitas of Brunswick, the long-separated branches of the house of Este were again united; Francis III. (1698–1780), who married the daughter of Philippe of Orleans, was named by the king of Spain generalissimo of the Spanish troops in Italy, had his duchy devastated by the imperial troops, but was re-established in its possession by the treaty of Aix-la-Chapelle, and having reconciled himself with Maria Theresa, received from her the title of governor-general of Lombardy; and, finally, Hercules Rinaldo (1727–1803), who at the peace of Campo Fermo lost the duchies of Modena and Reggio, and with whom the male branch of the house of Este died out. His only daughter was married to Ferdinand, third son of the emperor Francis I. Ferdinand was created duke of Breisgau, and dying in 1806 was succeeded by Francis IV., who in 1816 was restored to the duchies of Modena and Reggio, and on the death of his mother inherited also the duchy of Massa and Carrara. He died January 26, 1846, and was succeeded in 1846 by his son Francis V., who lost his possessions by the events of 1859. On his death in 1875 the male line of the Austrian branch of the Estensi became extinct, and the title passed to Archduke Francis eldest son of the Archduke Charles Louis. The children of Lady Murray, daughter of the earl of Kintore, by her marriage with August Frederick duke of Sussex, sixth son of George III. of England, assumed the old name Este, and claimed recognition as members of the royal family; but as the marriage was in violation of an Act regarding royal marriages passed in 1772, it was declared invalid, and their claims were set aside.

ESTELLA, a town of Spain, in the province of Navarre, is beautifully situated on the Ega, 25 miles S.W. of Pamplona. Its streets are wide and well paved, and it possesses several squares. It has six churches, three monasteries, an old castle, and a college which was formerly a university. Its principal industries are the manufacture of woollen and linen fabrics, and brandy making; and it has also a considerable trade in fruits, wine, and cattle. The surrounding country is very fertile, producing oranges, lemons, and other fruits, which are largely exported to England. Estella commands several defiles on the roads from the Castiles and Aragon, and on that account occupies a position of considerable strategetic importance. It was long the head-quarters of Don Carlos, who was proclaimed king there in 1833. In 1873 it was the chief stronghold of the Carlists, and in 1874, when driven from other places, they succeeded in retiring to Estella. On the 19th February, 1875, the Carlists in the town surrendered unconditionally, and with its loss the power of that faction almost immediately collapsed. The population of Estella is about 6000.

ESTEPA, the ancient *Astepa*, a town of Spain, in the province of Seville, is situated on the north side of Mount San Francisco, 60 miles E.S.E. of Seville. Its smaller streets are narrow and steep, but the principal ones are wide, level, and regular. It possesses an old castle and an old Gothic church, the latter said to be of Moorish origin. Its chief industries are the manufacture of oil, and of various kinds of coarse woollen cloth; and it has also a trade in grain, fruits, and cattle. The population is about 7500.

ESTEPONA, a maritime town of Spain, in the province of Malaga, is situated on the Mediterranean, 25 miles E.N.E. of Gibraltar. It contains an ancient castle and a fine parish church. It carries on an active fishing and coasting trade. The manufactures are chiefly linen, leather, earthenware, and bricks. The vicinity is very fertile, producing oranges, lemons, and other fruits, which are largely exported to England. The population of the town is about 9000.

ESTERHAZY. See Eszterházy.

ESTHER. The Book of Esther relates how a Jewish maiden, Esther, a foster-daughter of Mordecai, was raised to the position of queen by the Persian king Ahasuerus (Xerxes) after he had divorced Vashti; next, how she and her uncle Mordecai frustrated Haman's resolution to extirpate the Jews out of the Persian empire; how Haman fell, and Mordecai was advanced to his place; how Esther obtained the king's permission for the Jews to destroy all who might attack them on the day which Haman had appointed by lot for their extirpation; and lastly, how a festival was instituted to commemorate their deliverance. Its main object is to account for the origin of the feast of Purim, which from its cradle in the Persian capital had gradually made its way into other countries (Esth. ix. 19–32). The coloring of the narrative is entirely foreign. Frequent and minute references are made to the usages of the Persian court, while on the other hand the peculiar institutions of the Jews, and even Jerusalem and the temple, and the very name of Israel, are studiously, as it would seem, ignored. The name of God is not mentioned once, a phenomenon entirely unique in the Old Testament writings. From a theological point of view, the book is therefore not of much interest. It attracts the historical critic, however, by the strangeness and difficulty of its statements, while the ordinary reader cannot fail to be struck by the force and dramatic vividness of its literary form. Its early popularity is shown by the interpolated passages (as different as possible from the original) in the Septuagint and old Latin versions.

It was not until the 18th century that a critical examination of the book was made, with a view to determine its precise historical value, not, however, at first with sufficient impartiality or historical information. Eichhorn, the most moderate of the earlier critics, belongs to the 19th century. He has drawn up a long list of improbabilities of detail, some of which he thinks he can explain away, while others remain in full force. Subsequent critics have believed themselves to have discovered fresh difficulties, insomuch that Dr. Kuenen does not hesitate to say that "impossibilities and improbabilities pervade the whole narrative" (*Religion of Israel*, iii. 148). It is impossible to mention more than a few of these as a specimen. The very first verses of the book are great stumbling-blocks to a Western reader. We are there told that Ahasuerus, "who reigned from India even unto Ethiopia, over an hundred and seven and twenty provinces," gave a banquet which lasted 180 days, and at which (if we take the expressions of the narrative literally) the whole official world of the Persian empire was simultaneously present (Esth. i. 3, 4). Further on, we are told that Esther, on her elevation to be queen, kept her Jewish origin secret (ii. 10), although she had been taken from the house of Mordecai, who was known to be a Jew (iii. 4), and had remained in constant intercourse with him (iv. 4–17). We also learn indirectly that Mordecai, previously to his mourning, was able to pass at pleasure into the harem of the jealous and amatory Xerxes (iv. 2). Further, that Mordecai offered a gross affront to Haman without any evil consequences (iii. 2–6). Lastly, Haman, the cruel grand-vizier, takes the trouble to give eleven months' notice of his intention to exterminate the Jews (iii. 12–14), which respite is spent by the Jews in fasting (the narrative does not add praying) and lamentation (iv. 3), and when the danger has been averted through the patriotism of Esther, the Jews are allowed to put to death 75,000 of their fellow-subjects (ix. 16).

Nevertheless, it must at any rate be admitted that these objections are not all of equal value, and that a comparison of the narrative of Esther with the later additions to the book, and with the stories of Judith and Tobit, is distinctly favorable to its historical verisimilitude. Some amount of exaggeration must be allowed for, as the infirmity of an Oriental race; no exegesis is possible without such a postulate. As for the Persian customs described, they are no doubt singular, but, in the absence of documentary evidence, it is unsafe to give them a positive contradiction. At least one confirmation of some importance has been supplied by Herodotus (iii. 69, *cf.* Esth. ii. 12), and many critics hold that the assembly assigned to the third year of Ahasuerus (Esth. i. 3) is that mentioned by Herodotus (vii. 8) as having been held previously to the expedition against Greece. This, however, is quite uncertain. The reference to the 127 provinces is in itself not improbable, but is only confirmed by the author of the book of Daniel (vi. 1, *cf.* 1 Esd. iii. 3, LXX.), who has been thought by some to have made a confusion between satrapies and subsatrapies. It is at any rate in perfect harmony with history that the book of Esther includes India among the subject provinces; this is confirmed not only by Herodotus (iii. 94), but by the inscriptions of Darius at Persepolis and Naksh-i-Rustam. The conduct of Mordecai certainly remains mysterious. In our own day, the harem is impenetrable, while "any one declining to stand as the grand-vizier passes is almost beaten to death" (Morier, the English minister to the court of Persia, quoted by Dean Stanley). And if it is perhaps only too probable that a vizier would use his position for the gratification of spite, and if even the bloodthirstiness of Haman is not inconceivable, still the circumstances connected with the decree for the destruction of the Jews are almost more than even "the peculiarly extravagant and capricious character" of Xerxes (Canon Rawlinson) can render easily acceptable.

The proper names of Esther, at any rate in their present form, do not all of them stand philological tests. Some of them are genuinely Persian, but others wear a somewhat questionable appearance. These may either be corrupt, or, as Nöldeke suggests, framed by the author himself on Persian models. Among the most accurate is Ahasuerus or rather Akhashverosh (= Persian Chshayarsha, *i.e.*, Xerxes). The character of this king, too, agrees admirably with that given of Xerxes by Herodotus (*cf.* Herod. iii. 69, ix. 108). But then, it has been replied, it only agrees so well because Xerxes was a typical Oriental despot, magnificent, swayed by favorites, proud, amatory, capricious. Here we must leave this part of our subject—nothing short of a detailed commentary on the book would give the reader a satisfactorily complete view of the facts. It must, however, be observed that the serious chronological difficulty in Esther ii. 5, 6 (where Mordecai is apparently said to have been carried captive with Jeconiah) can hardly be removed by maintaining with Canon Rawlinson (contrary to Hebrew usage) that Kish, and not Mordecai, is the person referred to. It must, it would seem, be concluded that the theory that the book of Esther is a strictly historical narrative is not proof at all points against objection. The question then arises, is it a work of pure imagination? This was the view of the 18th century rationalistic critics. Semler, for instance, says, "Illud videtur esse certum, confictam esse universam parabolam, fastûs et arrogantiæ Judæorum locupletissimum testimonium" (Semler, *Apparatus ad liberal. Vet. Test. interpr.*, p. 152 *sq.*, quoted by Keil). By this theory, we might at once put a happy end to the guerilla warfare of rationalistic objectors. It is very necessary, however, to see how much is involved in accepting it. For the book of Esther expressly appeals to the authority of the royal Persian chronicles (ii. 23, x. 2) and of a contemporary memoir (ix. 32). If untrue, remarks Canon Rawlinson, the book might easily have been proved to be so at the time when it was published, by reference to those chronicles (*Speaker's Commentary*, iii. 472). The only way to turn the point of this objection would be to show that the narrative was written subsequently to the fall of the Persian empire, and not earlier than the end of the fourth century, about 150 years after Xerxes. This has been maintained by several eminent critics (*e.g.* Zunz, Herzfeld, Ewald, Bertheau, Kuenen) on the following grounds. (1) The absence of any reference to the story in the books (or rather book) of Chronicles, Ezra, and Nehemiah, in Daniel, in Ecclesiasticus (see chaps. xliv.–l.), or in Philo. (2) The way in which the Persian monarchy is described. A book so far from complimentary in some of its details to a great Persian king cannot, it is urged, have been written during the continuance of his dynasty, any more than the so-called Song of Solomon can have been written under the rule of the Solomonic family. True, the opening of Esther portrays in brilliant hues the outward splendor of Ahasuerus's empire, but the very brilliance, and still more the particularity, of the description, indicates that that empire was a wonder of the past, already beginning to be invested with the glamour of fairy-land. The necessity for an explanation of Persian customs (i. 13, viii. 8) is thought to point in the same direction. (3) "The absence of the religious spirit in the writer, or rather the absence of its manifestation. Had the writer lived soon after the events narrated, it is improbable that he would have omitted all [direct] mention of divine providence and the name of God, because the religious feeling had not so far degenerated among the Jewish captives who did not return to their own land with Zerubbabel, Ezra, and Nehemiah" (Dr. Davidson, *The Text of the Old Testament considered*, 1856, p. 609). In the Greek period, on the other hand, we know for certain from Ecclesiastes that the religious spirit was declining, at any rate in some circles, even in Judea. (4) The lateness of the style. This has been carefully investigated by Zunz, who remarks that there are more than fifty expressions which point to a late date, and which include, besides Persisms, three also found (and found only) in Ezra, Nehemiah, Ecclesiastes, one in Nehemiah, Ecclesiastes, and Ps. cxix., one in Chronicles, five in Ecclesiastes, one in Daniel, one in Chronicles and Daniel, one in Nehemiah and Daniel, also six belonging to later Hebrew, two to Aramaic, and four resembling the usage of the Mishna. The value of this argument, however, depends partly on the date which we assign to Chronicles, Ecclesiastes, and Daniel, also on the relation of Ezra and Nehemiah to Chronicles. The weighty reference to the Mishnaic usage remains, however, in full force, however conservative be our decision on the date of Chronicles, etc. We have said nothing at present of the festival of Purim, which, according to Keil, is "the principal evidence of the historical truth of the whole narrative," and which, even according to the more critical Friedrich Bleek, "undoubtedly pre-supposes the occurrence of what is narrated in our book." To many scholars, however, the connection of the book of Esther with the festival of Purim is rather a difficulty than otherwise. It is hardly necessary to refer to Mr. Tylor for evidence of the tendency to invent stories to account for popular festivals. Dr. Kuenen, who speaks as the representative of a growing school, maintains that the book of Esther is through and through unhistorical, that "the explanation it offers of the Purim feast is not taken from the reality, but *invented* to make that feast popular. A Persian word *pur* meaning lot is quite unknown" (*Religion of Israel*, iii. 148). He then fortifies his position by a reference to the numerous improbabilities which we have already mentioned. According to him, Purim was originally a Persian feast, and was by degrees adopted by the Jews, first in Persia, and then in other countries, and the object of the author of Esther was to make the observance of the feast still more general. He is not, however, prepared with a satisfactory explanation of the word Purim. Von Hammer's derivation from *furdigán* the name of a Persian festival falls through, as Dr. Kuenen points out, owing to the fact that *furdigán* was not a spring feast, and, as Purim was kept on the 14th and 15th of the month Adar, a spring feast is obviously required. A more plausible form of the hypothesis adopted by Dr. Kuenen is perhaps that of Zunz. The Jews during and after the exile were much influenced religiously by the nations among whom they lived (so at least many critics believe, quoting as instances the belief in the seven archangels and in Azazel). It was the policy of the doctors of the law to adopt as many of the new popular usages as they could, without detriment to the purity of their religion. Purim, a joyous, secular festival, enjoyed (as it still does enjoy) a great popularity among the Jews. The religious authorities, desiring to check the exuberance of its celebration, determined to give it a quasi-consecration by connecting it with an event (real or imaginary) in the history of the nation. They omitted the name of God, not from indifference to religion, but to prevent it from being profaned at the secular celebration to which Purim was liable (*cf.* Esther ix. 19–22). It must be observed, in conclusion, that while the doctors of the law attached great importance to Purim and to Esther—witness the statement that the men of the Great Assembly "wrote" (? edited) the book of Esther, also the various interpolated passages, and the devotion of an entire Talmudic treatise to the feast of Purim—the sacerdotal authorities (of a more conservative turn) did their utmost to disparage the intrusive festival. No psalms were sung in the temple at the feast of Purim—not even those which were usual at half festivals (see Bloch, *Hellenistische Bestandtheile im biblischen Schriftthum*, pp. 39–41). The first mention of Purim occurs in 2 Macc. xv. 36, where the thirteenth day of Adar is said to have been observed as a festival in memory of the death of Nicanor, "the day before Mardocheus's day." Unfortunately the second book of Maccabees was written little, if at all, before the Christian era, while the first book (of much greater authority) simply says (vii. 49):—"They ordained to keep yearly this day, being the thirteenth of Adar." Would the Jews, asks Dr. Zunz, have made a new festival on the 13th, if the 14th were recognized as the feast of Purim? This, however, may well be called hypercriticism. And we may sum up by the remark that if direct historical evidence is deficient for the traditional view of the book of Esther, it is equally deficient for the rival critical theory. Probability is our only guide. Yet even if the book contain a larger or smaller romantic element, it is of real historical value as a record of the Jewish spirit in a little known age, and is edifying even to Christians from its powerful though indirect inculcation of the lesson of divine providence.

ESTHONIA (in German *Esthland*, or more correctly *Ehstland*, in the native language *Wiroma*, "the frontier country," or *Rahwama*, "the country of the Rahwas or Esthonians," in Lettish *Iggaun Senna*, probably "the land of the banished"), one of three Baltic or so-called German provinces of Russia, is bounded on the N. by the Gulf of Finland, on the E. by the government of St. Petersburg, from which it is separated by the river Narowa, on the S. by Livonia, and on the W. by the Baltic. Inclusive of the islands of Dago, Mohn, and Oesel, it has an area of 7817 square miles. It consists essentially of a nearly level plateau of Silurian limestone which presents to the Gulf of Finland a precipitous coast from 49 to 120 feet in height, has a gradual slope inland to the south, and is broken by three or four slightly marked terraces running E. and W. Traces of glacial action are exceedingly abundant in the shape of drift and boulders, both on the mainland and in the islands. A considerable portion of the surface is occupied by stretches of sand, marsh, or pine forests; but other parts afford a good arable soil. There are a great number of small lakes throughout the country, and on the eastern frontier lies the Ozero Tchudskoye or Peipus Lake, about 55 miles long and 30 broad. None of the rivers are large enough to be of real commercial importance. The climate is severe with long winters and frequent storms. Most of the population is engaged in agricultural pursuits—cattle, barley, rye, hemp, flax, and tobacco receiving their chief attention. With the exception of the distilling of brandy and the weaving of a little linen and cloth there is no manufacturing industry, and foreign commerce is almost entirely confined to Reval, Baltischport, and Hapsal. The province is administratively divided into the six districts of Reval, Wesenberg, Weissenstein, Hapsal, Leal, and Kunda, and the city of Reval is the seat of the principal Government officials. The national church is Lutheran; but it is gradually losing ground before the encroachments of Greco-Russian proselytism strongly supported by the political authorities. It divides the country into eight dioceses, and places the centre of its administration in a consistorium at Reval. In 1875 there were 578 schools, attended by 18,952 boys and 16,227 girls, or in other words, by 92 pupils out of every 1000 inhabitants. The higher education under the influence of the nobility and clergy keeps for the most part true to German traditions. Out of a population numbering 323,961 in 1870 about one-thirteenth is of German race; and the province may be briefly characterized as a country fundamentally Esthonian, with a Teutonic aristocracy and a Russian government. The Esthonians proper belong to the Finnish family, and still maintain their native language. Howorth, however, has recently endeavored to show that their settlement in the Baltic district is after all not of such high antiquity. Perhaps none of the nationalities of Europe have maintained greater purity of descent, and the general opinion is that they are the aboriginal occupants of the soil. They are not confined to the country with which they are nominally identified, but form more than a third of the population of Livonia or Liefland, and are found in isolated districts in the governments of Vitepsk, Pskoff, and St. Petersburg. Altogether they are estimated at about 650,000. In physical development they do not rank high and appear to bear the marks of long-continued hardship and servitude. They are generally short in stature, especially in the neighborhood of Dorpat. The skull is angular and brachycephalous, the forehead low, the space between the nostrils and mouth short, the hair usually yellowish or brown, and the beard scanty. Their language is rich in roots, and has no small flexibility of composition and structure. There are two main dialects—the Dorpat or Werro Esthonian and the Reval Esthonian—which are nearly as distinct from each other as Polish and Bohemian, and can hardly be successfully treated in a common grammar. The latter, which preserves more carefully the full inflexional forms, and pays greater attention to the laws of euphony, is consequently recognized as the literary speech, and has the wider domain. It breaks up again into two varieties, the one of which, like the Livonian and Tchudish, uses strong forms of words, while the other, like the literary Finnish, indulges in weak forms. Minor varieties are exceedingly numerous—almost every parish, according to Wiedemann, having recognizable peculiarities. The first publication in Esthonian was a Lutheran catechism, prepared at the suggestion of Heinrich von Galen, master of the Livonian order in the 16th century. In 1637 appeared an Esthonian grammar by Stahl, and in 1648 a similar work by Hutslev. A translation of the New Testament by a learned society was printed at Reval in 1715, and in 1780 Hupel published his Esthonian-German lexicon, with a grammar of the two principal dialects. Between 1813 and 1832 there appeared at Pernau twenty volumes of *Beiträge zur genauern Kenntniss der Esthnischen Sprache*, by Rosepländer, and from 1840 downwards A. von Jannau, Fr. Fählmann, Aug. Heinrich Hansen, Knupffer, Haller, and others contributed valuable papers on Esthonian subjects to the *Verhandlungen der Gelehrten Esthnischen Gesellschaft*. In 1844 appeared Ahren's *Grammatik der Esthnischen Sprache Revalischen Dialects*, which, however, recognizes only the weaker form of the dialect. More recently F. J. Wiedemann under the auspices of the Imperial Academy of St. Petersburg has devoted himself to the detailed investigation of Esthonian, visiting the different parts of the country, and registering all peculiarities on the spot. Reports of his labors are given in the *Bulletin* of the society, and his lexicon was published in 1869. The popular songs and traditions of the Esthonian are numerous and interesting; they have a close resemblance to the similar productions of Finland, and many of them embody portions of an old heathen mythology and cosmogony. The last professional rhapsodist is said to have died in 1813. Rouss published a collection of *Esthnische Volksleider* in 1850–51, several of which may be found translated in Latham's *Nationalities of Europe*, vol. i.; Dr. Fr. Kreutzwald, with questionable judgment, united a number of the separate songs into a connected poem (Helsingfors, 1866); and his work has been translated by Carl von Reinthal as *Die Esthnische Sage von Kalewipoeg*, 1857, 1859. Still more recently Jacob Hurt has commenced at Dorpat what is intended to be a complete collection of old Esthonian popular poetry, under the title of *Vana Kanal*, or "The Old Harp."

The Esthonians are mentioned in the 11th century by Adam of Bremen, and in the 12th and 13th the name becomes quite familiar. They appear to have given no small trouble to their Scandinavian neighbors by their piratical excursions, and several of the Danish kings attempted to bring them into subjection. Canute IV., or Knud Valdemarson, invaded their country with a fleet of 760 ships, forced many of their number to submit to the rite of baptism, and erected several Christian churches; but hardly had his ships disappeared when the churches were in ruins, and the conversions proved to be a pretence. In 1219 Valdemar Seier, or the Victorious, received the papal blessing, and undertook another and more formidable crusade. The Danish soldiers vowed a vow that, if victory was granted to their arms, every Dane of twelve years and upwards would from henceforth hold a fast on St. Laurence's Eve. At first they were apparently successful; but after they deemed their conquest secure, the Esthonians fell upon them unawares, and pressed them so hard that, as the tale is told, their defeat would have been inevitable, had not the archbishop, Anders Suneson, like another Moses, ascended a hill and held up his hands in benediction and prayer. The victory thus obtained was commemorated by the creation of thirty-five knights on the field of battle, who, it may be noted, were the first members of their order in Denmark. Though their country was incorporated with the Danish kingdom, the Esthonians proved by no means submissive subjects, and we find several of Valdemar's successors obliged to suppress their insurrections by force. At length Valdemar Atterdag, after the great rebellion of 1343, sold his troublesome possession in 1347 to the Knights of the Sword for 19,000 marks; and the history of Esthonia is in consequence practically the history of that order till the 16th century. The nobles and cities offered voluntary homage to Sweden in 1521, but the Swedish kings found it no easy task to maintain their claim against the Russian encroachments, which had begun as early as 1483. The foolish ambition of Charles XII. decided the matter against them; and in 1721, by the peace of Nystadt, Esthonia was formally ceded to Peter the Great, who did what he could to conciliate the inhabitants, both Esthonians and Germans. Serfdom was abolished in 1817 by Alexander I., but the condition of the peasants continued so unsatisfactory that they rose in rebellion in 1859. The struggle between German and Russian influences is still going on, but it can hardly end in anything else than Russian domination.

See, besides the work already mentioned, Hupel, *Topographische Nachrichten*, Riga, 1774–82; Petri, *Esthland und die Esthen*, 1802; Willigerod, *Geschichte Esthlands*, 1817; Merkel, *Die freien Letten und Esthen*, 1820; Ewer, *Des Herzogthums Esthlands Ritter und Landrechte*, Dorpat, 1821; T. ESTIENNE, Stephanus, or Stephens, a celebrated French family of printers. See Stephens.

ESTOPPEL, in law, is where a party in litigation is not permitted to assert or deny something, when such assertion or denial would be inconsistent with his own previous statements or conduct. Estoppel is said to arise in three ways—(1) by record or judgment, (2) by deed, and (3) by matter *in pais* or conduct. (1.) Where a cause of action has been tried and final judgment has been pronounced, the judgment is conclusive—either party attempting to renew the litigation by a new action would be estopped by the judgment. "Every judgment is conclusive proof as against parties and privies of facts directly in issue in the case, actually decided by the court, and appearing from the judgment itself to be the ground on which it was based."—Stephen's *Digests of the Law of Evidence*, Art. 41. (2.) It is one of the privileges of *deeds* as distinguished from simple contracts that they operate by way of estoppel. "A man shall always be estopped by his own deed, or not permitted to aver or prove anything in contradiction to what he has once so solemnly and deliberately avowed" (Blackstone, 2 *Com.*, 295); *e.g.*, where a bond recited that the defendants were authorized by Acts of Parliament to borrow money, and that under such authority they had borrowed money from a certain person, they were estopped from setting up as a defence that they did not in fact so borrow money, as stated by their deed. (3.) Estoppel *in pais* is the most important head. The rule practically comes to this, that, when a person in his dealings with others has acted so as to induce them to believe a thing to be true and to act on such belief, he may not in any proceeding between himself and them deny the thing to be true; *e.g.*, a partner retiring from a firm without giving notice to the customers, cannot, as against a customer having no knowledge of his retirement, deny that he is a partner. As between landlord and tenant the principle operates to prevent the denial by the tenant of the landlord's title. So if a person comes upon land by the license of the person in possession, he cannot deny that the licenser had a title to the possession at the time the license was given. Again, if a man accepts a bill of exchange he may not deny the signature or the capacity of the drawer. So a person receiving goods as bailee from another, cannot deny the title of that other to the goods at the time they were entrusted to him.

ESTREMADURA (commonly derived from *extrema ora*, compare Land's End, Finistère, etc.), a province of Portugal, bounded on the N. and N.E. by Beira, on the S. and S.E. by Alemtejo, and on the W. by the Atlantic Ocean. It lies between 38° 6′ and 40° 15′ N. lat., and between 7° 43′ and 9° 32′ W. long., being about 140 miles in length from N. to S. by about 80 miles in breadth. The river Tagus divides it into two nearly equal parts, the northern being the more mountainous, but at the same time the more fertile, of the two. A chain of mountains extending from Beira traverses the northern portion from N.N.E. to S.S.W., and terminates on the coast between the estuary of the Tagus and the sea. This range sends off spurs in various directions. Between Torres Vedras and Lisbon is an extensive chain of points, some formed by nature and others by art, and stretching in a general direction from E. to W. Along these Lord Wellington constructed a series of defensive works called the "Lines of Torres Vedras," by means of which he was able successfully to resist the advance of the French invaders. This mountain chain attains a height of 2300 feet, and separates the streams which fall into Tagus from those that flow directly into the sea. The part lying N.W. and between it and the sea is mostly flat and sandy towards the coast, and either barren or covered with forests of pines. For about 50 miles N. of the mouth of the Tagus, however, or as far as Peniche, the coast consists of rocky cliffs, some of which attain a great elevation. South-east of the ridge, and sloping towards the Tagus, the country is finer and better cultivated. The plains about Tomar and Santarem are very fertile, and abound with olive and other fruit trees. But the finest part of the province is that which lies S. of the lines of Torres Vedras towards Lisbon. Here the valleys are covered with villages, country seats, gardens, orchards, and vineyards. In Estremadura the general system of land tenure was formerly that known as "Ingadas," by which the farmer paid a rent in corn or produce for each yoke of oxen lent out to him by the landlord. A modification of this tenure yet exists, and its results are seen in the bad and backward farming which prevails. South of the Tagus the country is mostly low and flat, and in several places unhealthy. The land rises towards Alemtejo, and several ranges of hills proceeding from that province enter Estremadura. The principal river is the Tagus, which falls into the sea below Lisbon. The Zezere is a large and rapid stream which rises in Beira, and flowing southward falls into the Tagus below Punhete. The Zatas and Almansor both rise in Alemtejo, and flow at a short distance from each other into the eastern of the two branches into which the Tagus is divided above Lisbon. The principal rivers flowing directly to the sea are—in the northern portion, the Lis, Alcoa, Arnoya, and Zizambre, and in the southern the Maroteca and the Sado, the last being the largest. Estremadura is divided into the three districts of Lisbon, Santarem, and Leiria. The population of the province in 1871 was 839,691.

ESTREMADURA, an old province of Spain, divided in 1833 into the provinces of Badajoz and Caceres, lies between 37° 58′ and 40° 32′ N. lat., and between 4° 32′ and 7° 26′ W. long., being about 180 miles in length from N. to S. by 130 in extreme breadth, and having an area of 14,280 square miles. It is bounded on the N. by Salamanca and Avila, E. by Toledo and La Mancha, S. by Cordova and Sevilla, and W. by Portugal. The Tagus and the Guadiana cross the province from E. to W., and their respective basins form two natural and nearly equal divisions,—that of the Tagus, being the northern, called Alta or Upper Estremadura, and that of the Guadiana, Baja or Lower Estremadura. These two basins are separated from each other by a range of mountains, of which the eastern and higher portion attains an elevation of from 5000 to 6000 feet above the level of the sea. This natural division corresponds to the division into the provinces of Badajoz and Caceres, the former being Baja Estremadura, and the latter Alta Estremadura. The basin of the Guadiana is bounded on the S. by a continuation of the Sierra Morena, which fills up the southern part of the province with hilly ground, and divides the waters of the Guadiana from those of the Guadalquivir. A branch of this chain proceeds northward from the confines of Cordova to the Guadiana. The basin of the Tagus is bounded on the N. by a range of mountains which proceed westward from Avila along the boundaries between

Estremadura and Salamanca, and afterwards enter Portugal. From this northern range a branch proceeds in a S.W. direction between the rivers Alagon and Tietar; from the eastern part of the central range a branch proceeds in a N.W. direction to the Tagus. The climate in summer is hot, but not unwholesome, except in some swampy places along the Guadiana. There is then but little rain; dew, however, is abundant, and sufficient to moisten the ground; and the nights are cool. Although the high mountains are covered with snow in the end of November, the winters are not severe. The soil is very fertile, and might be rendered highly productive by a proper use of the waters of the many rivers by which it is intersected. Agriculture, however, is wholly neglected, and the noble plains that might yield abundance of all sorts of products are devoted only to pasturage. Vast numbers of merino sheep come annually from other parts to winter in these plains. Immense herds of swine are reared in the province, and constitute a great source of support to the inhabitants, not only supplying them with food, but also forming a great article of export to other provinces,—the pork, bacon, and hams being in high esteem. The extensive forests of oak, beech, and chestnuts afford an abundance of food for hogs. Olive, fruit, and cork trees are numerous. Game is abundant, and fish swarm in the rivers and streams. Estremadura has mines of lead, copper, silver, and iron, but these are almost totally neglected; and the manufactures are few. The chief products are corn, wine, oil, hemp, and flax. The population of Estremadura in 1870 was 734,377.

ESTREMOZ, a town of Portugal, in the province of Alemtejo, 22 miles W. of Elvas on the road to Lisbon. It was once a strongly fortified place with accommodation for a garrison of 20,000 men, but its citadel and forts are now falling into decay. There are marble quarries in the neighborhood, and the Estremoz *bucaros*, a kind of jar with a pleasant odor, are well known throughout Portugal. The queen of Portugal, St. Elizabeth, died in the town in 1336. Population about 6600.

ESZÉK, Germ. *Esseck* or *Essegg*, Slav. *Oszek*, a fortified royal free town of Hungary, province of Croatia-Slavonia, situated on the right bank of the Drave, 13 miles from its confluence with the Danube, in 45° 33′ N. lat., 18° 43′ E. long. The town is divided by a wide esplanade into four parts, viz., the fortress or town proper, the upper, the lower, and the new town. The most important buildings are the barracks, capable of accommodating 30,000 men, the town hall, and the old county hall. It has also Roman Catholic, Greek, and other churches, four silk-weaving factories, a gymnasium, and a normal high school. A wooden bridge crosses the Drave and the swampy ground adjoining. There is steam communication with several places on the Upper Danube, and the trade in raw hides, cattle, and corn is very extensive. Eszék stands on the site of the ancient Roman town Mursia Ælia, founded by the emperor Hadrian, 125 A.D., and afterwards became the capital of Lower Pannonia. The town was made the seat of a bishopric by Constantine in 335, which, however, ceased to exist after the destruction of the colony by Attila in 447. The Slavonians settled there in the 6th century. In 1526 Eszék was occupied by the Turks, who having defeated the Germans there in 1537, remained for about a century and a half in possession of the town, which ultimately came under Austrian rule in 1687. Eszék surrendered to the Hungarians in October, 1848, but was retaken by the Austrians on the 14th February, 1849. It has been a royal free town since 1809. Population in 1870, 17,247.

ESZTERHÁZY, the name of an ancient, influential, and wealthy Hungarian family, which some genealogists derive from a descendant of Attila, a certain Paul Estoraz, who embraced Christianity in 969 A.D. Authentic accounts, however, do not extend beyond 1238, when the family was divided into the two branches of Zerházy and Illesházy, the latter of which became extinct in 1838. Francis Zerházy changed the name in 1584 to Eszterházy, and his descendants separated into the three existing branches:—Csesznek, Zólyom or Altsohl, and Fraknó or Forchtenstein.

PAUL IV., Prince Eszterházy de Galanta, the head of the third branch, was born at Eisenstadt, September 7, 1635. At an early age he became field-marshal, and distinguished himself in the wars against the Turks. In 1681 he was made Palatine of Hungary. In 1683 he assisted in the deliverance of Vienna, and in 1686 of Ofen from the hands of the Turks, and thus contributed to establish the power of the house of Austria in Hungary, for which services he was in 1687 created a prince of the Holy Roman Empire. He died 26th March, 1713.

NICHOLAS JOSEPH, Prince Eszterházy de Galanta, Count of Forchtenstein, born 18th December, 1714, was the grandson of Paul IV. He distinguished himself in Silesia in 1745 at the head of the Hungarian troops, but is chiefly known as a patron of the arts and sciences. He was, moreover, a diplomatist, and served as ambassador at various courts. He died 28th September, 1790.

NICHOLAS IV., Prince Eszterházy de Galanta, grandson of the last-named, was born 12th September, 1765. In his youth he visited the chief countries of Europe, and served for some time in the Austrian army, where he became field-marshal, but he afterwards entered the diplomatic corps. He was a great patron of the arts and sciences, and founded an important picture-gallery in his castle at Vienna. He also transformed his country seat at Eisenstadt into a temple of music and botany, and erected a fine mausoleum there to Haydn. In 1809, when Napoleon wished to weaken the Austrian power by the separation of Hungary, he is said to have offered the Magyar crown to Eszterházy, who, however, firmly refused it. He died at Como in Italy, 25th November, 1833.

PAUL ANTHONY, Prince Eszterházy de Galanta, son of Nicholas IV., was born 11th March, 1786, and devoted himself to diplomacy. In 1810 he was ambassador at Dresden, in 1814 at Rome, and from 1815 to 1818, and again from 1830 to 1838, at the court of England, where he gained the reputation of being an able diplomatist. He subsequently directed his energies to the support of the rising Hungarian national movement, and, in 1848, accepted the post of minister of foreign affairs in the Batthyáni administration, where he endeavored to bring about a reconciliation between the Austrian and the Hungarian ministry. After the suppression of the revolution, he retired into private life. In 1856, he represented Austria at the coronation of Alexander II., emperor of Russia. He died at Ratisbon 21st May, 1866.

ETAH, a district and town of British India, in the lieutenant-governorship of the north-western provinces, and included in the division of Agra. Etah District stretches along the eastern edge of the Duáb or alluvial plain enclosed by the Ganges and the Jumna, and lies between 27° 20′ 30″ and 28° 1′ N. lat., and between 78° 29′ and 79° 19′ 30″ E. long. It is bounded on the N. by the Ganges, on the W. by the districts of Agra and Alígarh, on the S. by the district of Mainpuri, and on the E. by that of Farrakhábád. The total area of the district is 1512 square miles, of which 970 are cultivated. The total population, according to the census of 1872, amounts to 703,527 souls, comprising 636,149 Hindus, and 67,278 Mahometans. The males number 382,746, the females 320,739, the proportion of males to the total population being 54·5 per cent. The principal tribes and castes in point of number are:—(1) Bráhmans, 60,691; (2) Rájputs, 57,025; (3) Baniyas or traders, 13,056; (4) Chámárs or manual laborers, 86,635; (5) Ahirs, 76,754; besides numerous minor clans. The density of population is 465 persons to the square mile. The district consists for the most part of an elevated alluvial plateau, dipping down on its eastern slope into the valley of the Ganges. The uplands, however, are not so fertile as in most of the neighboring districts, owing to the insufficiency of the water supply; while patches of a barren saline efflorescence occasionally interrupt the cultivated expanse. Between the modern bed of the Ganges and its ancient channel lies a belt of fertile land, covered with a rich deposit of silt, and abundantly supplied with natural moisture. A long line of swamps and hollows still marks the former course of the river; and above it rises abruptly the original cliff which now forms the terrace of the upland plain. The Káli Nadi, a small stream flowing in a deep and narrow gorge, passes through the centre of the district, and affords an outlet for the surface drainage. The tract of country to the west of this river is irrigated by the Cawnpur and Etáwah branches of the Ganges canal; and another work, now in progress, will supply abundant water in future to the dry plateau on the east.

No railway passes through the district, but good metalled roads connect the chief towns, and the Ganges affords a means of transport for heavy goods. The principal agricultural products comprise wheat, barley, pulses, millets, cotton, sugar-cane, indigo, and opium. Two harvests a year can be taken off the land, in the spring and the autumn. Etah exports large quantities of food-grains and other produce to neighboring districts. Indigo is manufactured in 200 factories, some of which are conducted by English capital. Eight towns in 1872 contained a population exceeding 5000:—Etah, 8044; Márahra, 9214; Soron, 11,182; Saháwar, 5156; Sakít, 5415; Dundwáraganj, 5414; Alíganj, 7912; Kásganj, 15,764. In 1870 the total revenue of Etah district from all sources amounted to £119,399, of which £78,852 was due to the land-tax. The five municipalities of Kásganj, Etah, Soron, Márahra, and Alíganj possess a joint income of £4878. The climate is dry and healthy, but sand and dust storms frequently occur.

Etah was at an early date the seat of a primitive Aryan civilization, and the surrounding country is mentioned by Hiouen Thsang, the Chinese Buddhist pilgrim of the 7th century A. D., as rich in temples and monasteries. But after the bloody repression of Buddhism before the 8th century, the district seems to have fallen once more into the hands of aboriginal tribes, from whom it was wrested a second time by the Rájputs during the course of their great migration eastward. With the rest of Upper India, it passed under the sway of Mahmud of Ghazni in 1017, and thenceforth followed the fortunes of the Mahometan empire. At the end of the last century it formed part of the territory over which the vazír of Oudh had made himself ruler, and it came into the possession of the British Government in 1801, under the treaty of Lucknow. During the mutiny of 1857 it was the scene of serious disturbances, coupled with the usual anarchic quarrels among the native princes.

Etah Town, the capital of the district, stands on the Grand Trunk Road, in 27° 33′ 50″ N. lat., and 78° 42′ 25″ E. long. The population in 1872 numbered 8044 souls, comprising 5884 Hindus, 2150 Mahometans, and 10 Christians. Before the period of British rule the town had little importance, and at present it is chiefly noticeable as the administrative headquarters for the district. It contains a handsome temple and large tank, with the usual public offices of a district capital. The municipality had an income in 1874–75 of £1183, of which £845 was raised by an octroi duty. The incidence of taxation was at the rate of 2s. per head of the population.

ÉTAMPES, or Estampes, a town of France, capital of an arrondissement of the same name in the department of Seine-et-Oise, is situated on the Paris and Orleans railway, 30 miles S. by W. of Paris, in a fertile valley, on the banks of two small streams, which fall into the Seine immediately below the town. It is the seat of a tribunal of primary instance, a communal college, and an agricultural society. Its most remarkable building is an old tower called Guinette, which is all that now remains of an ancient royal castle built in the 11th century by King Robert, in which Philip Augustus kept his wife a prisoner from 1199 to 1201. Étampes has three ancient churches—Notre-Dame built in the 13th century (with a lofty tower and spire), the church of St. Martin, and the church of St. Basil. In the square there is a statue of Étienne Geoffroy Sainte-Hilaire, who was born in Étampes. The principal manufactures of the town are woollen goods, soap, and leather; and it sends large supplies of corn, meal, vegetables, and honey to Paris. Étampes is very old. In 886 it was plundered by the Normans, and it was conquered by the prince of Condé in 1652. The population in 1872 was 7511.

ETÁWAH, a district and city of British India, in the lieutenant-governorship of the North-Western Provinces, and included in the division of Agra. Etáwah District forms a purely artificial administrative division, stretching across the level plain of the Duáb, and beyond the valley of the Jumna, to the gorges of the Chambal and the last rocky outliers of the Vindhyan range. It lies between 26° 20′ 30″ and 27° N. lat., and between 78° 45′ 45″ and 79° 47′ E. long., and is bounded on the N. by Mainpuri and Farrakhábád districts; on the W. by the Jumna, the Agra district, the Chambal, the Kuári Nadi, and the native state of Gwalior; on the S. by the Jumna; and on the E. by Cawnpur district. The total area of the district is 1691 square miles, of which 880 are cultivated. The total population, according to the census of 1872, amounts to 668,641 souls, comprising 631,923 Hindus, 36,571 Mahometans, and 147 Christians. The males number 369,928, the females 298,653, the proportion of males to the total population being 55·3 per cent. The principal tribes or castes are as follows:—(1) Bráhmans, 93,082; (2) Rájputs, 58,358; (3) Baniyas or traders, 32,693; (4) Chamárs, 96,923; (5) Ahirs, 75,035; (6) Kachhis, 48,160; (7) Lodhas, 34,795; (8) Gadariyas, 21,926; and (9) Kolis, 20,391. The density of population is 395 persons to the square mile. The district exhibits a striking variety of surface and scenery. The greater portion lies within the Duáb or level alluvial plain between the Ganges and the Jumna. This part falls naturally into two sections, divided by the deep and fissured valley of the river Sengar. The tract to the north-east of that stream is rich and fertile, being watered by the Cawnpur and Etáwah branches of the Ganges canal, which will soon be supplemented by other important works now in progress. The south-western region has the same natural advantages, but possesses no great irrigation system, and is consequently less fruitful than the opposite slopes. Near the banks of the Jumna, the plain descends into the river valley by a series of wild ravines and terraces, inhabited only by a scattered race of hereditary herdsmen. Beyond the Jumna again a strip of British territory extends along the tangled gorges of the Chambal and the Kuári Nadi, far into the borders of the Gwalior state. This outlying tract embraces a series of rocky glens and mountain torrents, crowned by the ruins of native strongholds, and interspersed with narrow ledges of cultivable alluvium.

The East Indian Railway runs through the centre of the district. The Jumna forms a great water-way for the heavy traffic; while good roads connect most of the local centres with one another, and with the neighboring cities. The principal crops are wheat, barley, pulses, millets, sugar cane, cotton, and indigo. The district is essentially agricultural, and its exports consist entirely of the rural produce. Four towns in 1872 possessed a population exceeding 5000:—Etáwah, 30,549; Phaphund, 6536; Auráiya, 6459; and Jaswantnagar, 5310. In 1873 the total revenue of Etáwah district amounted to £191,097, of which sum £128,540 was contributed by the land-tax. The town of Etáwah has the only municipality in the district. The climate, once hot and sultry, has now become comparatively moist and equable under the influence of irrigation and the planting of trees.

Etáwah was marked out by its physical features as a secure retreat for the turbulent tribes of the Upper Duáb, and it was not till the 12th century that any of the existing castes settled on the soil. After the Mussulman conquests of Delhi and the surrounding country, the Hindus of Etáwah appear to have held their own for many generations against the Mahometan power; Bábar conquered the district with the rest of the Duáb, and it remained in the hands of the Mongols until the decay of their empire in the last century. After passing through the usual vicissitudes of Marhattá and Ját conquests during the long anarchy which preceded the British rule, Etáwah was annexed by the vazír of Oudh in 1773. The vazír ceded it to the English in 1801, but it still remained so largely in the hands of lawless native chiefs that some difficulty was experienced in reducing it to orderly government. During the mutiny of 1857, serious disturbances occurred in Etáwah, and the district was occupied by the rebels from June to December; order was not completely restored till the end of 1858.

Etáwah Town, the capital of the district, is picturesquely situated amongst the ravines on the bank of the Jumna, 70 miles S.E. of Agra. According to the census of 1872, its population amounts to 30,549 souls, comprising 21,241 Hindus, 9256 Mahometans, and 52 Christians. Deep fissures intersect the various quarters of the town, over which broad roads connect the higher portions by bridges and embankments. A fine modern square, known as Humeganj, from the name of its founder, stands in the centre of the city, and contains the chief public buildings. A handsome mosque, the Jama Masjid, forms the chief architectural ornament of Etáwah. It was originally a Hindu or Buddhist temple, and has been adapted to its present use by the Mahometan conquerors. Several Hindu temples also stand about the ruins of the ancient fort. The chief trade is in *ghi*, grain, cotton, and oil-seeds. The Etáwah municipality had an income of £3064 in 1875–76, of which £2435 was raised by taxes; the incidence of municipal taxation was 1s. 7¼d. per head of the population.

ETCHMIADZIN, Edchmiadzin, or Itsmiadsin, a town and monastery in the Russian government of Erivan, famous as the seat of the Catholicus or primate of the Armenian church. It is situated in the plain of the Aras or Araxes, about 2985 feet above the sea, 12 miles W. of Erivan and 30 N. of Mount Ararat. The monastery comprises a pretty extensive complex of buildings, and is surrounded by brick walls 30 feet high, which, with their loopholes and towers, present the appearance of a fortress. Its architectural character has been considerably impaired by additions and alterations in the modern Russian style. On the western side of the quadrangle is the residence of the primate, on the south the refectory, built by the Catholicus Abraham (1730–1735), on the east the lodgings for the monks, and on the north the cells. The cathedral is a small but fine cruciform building with a Byzantine cupola at the intersection, a large tower at the western end, and a smaller tower above each wing of the transepts. Of special interest is the porch, built of red porphyry, and profusely adorned with sculptured designs somewhat similar to those of Gothic architecture. The interior of the church is decorated with Persian frescoes of flowers, birds, and scroll-work. It is here that the Catholicus confers episcopal consecration by the sacred hand of St. Gregory; and here every seven years he prepares with great solemnity the holy oil which is to be used throughout the churches of the Armenian communion. Of the numerous relics the chief are the head of the spear which pierced the Saviour's side, a piece of Noah's ark, presented by an angel to St. James of Nisibis, and a piece of the true cross. Outside of the main entrance are the alabaster tombs of the primates Alexander I. (1714), Alexander II. (1755), Daniel (1806), and Narses (1857), and in hospitable contiguity a white marble monument erected by the East India Company to mark the resting-place of Sir John Macdonald, who died at Tabriz in 1830, while on an embassy to the Persian court. The library of the monastery is said at one time to have contained 15,000 volumes, and in spite of depredation and neglect, it still remains a rich storehouse of Armenian literature. Brosset's *Catalogue de la Bibliothèque d'Etchmiadzin*, St. Petersburg, 1840, contained only 635 numbers, but the new list drawn up by the monks (a copy of which was presented by Major Cunnyngham to the Oriental Library at Cambridge) mentions 2500 volumes, many of great size. Among the more remarkable manuscripts are a copy of the gospels in a massive binding of carved ivory dating from the 10th or 11th century, and three Bibles of the 13th century, one of which had belonged to Aytoun II., king of Armenia. A type-foundry, a printing-press, and a book-binding establishment are maintained by the monks, who publish a weekly Armenian newspaper called *The Ararat*, and supply religious and educational works for their co-religionists. The number of inmates in the monastery varies considerably. In 1834, according to Dubois, there were 50 monks and 13 bishops and archbishops; and in 1872, according to Telfer, there were 5 bishops and archbishops, 20 monks, and 25 novices. The revenue, estimated at £10,000, is derived from the conventual domains, which, though much less extensive than they once were, still comprise, not only a number of estates, but five villages presented or rather restored by the Russian emperor. The Catholicus has an annual income of 10,000 rubles. To the east of the monastery is a college and seminary of modern erection. At the distance of about half a mile stand the churches of St. Rhipsime and St. Gaiana, two of the early martyrs of Armenian Christianity; the latter is of special interest as the burial-place of all those primates who are not deemed worthy by the synod of interment beside the cathedral. From a distance the three churches form a fairly striking group, and accordingly the Turkish name for Etchmiadzin is simply Utch-Kilissi, or the Three Churches. A fourth of less importance is ignored. The town of Etchmiadzin, or as it should be called Vagharshapat, contains about 8000 inhabitants, but has long ceased to be of any individual importance. According to Armenian historians it dates from the 6th century B.C., and takes its name from King Vagarsh, who in the 2d century A.D. chose it as his residence and surrounded it with walls. The great apostle of Armenia, St. Gregory the Illuminator, having seen the Saviour descend in a flood of light in the neighborhood of the palace, was ordered by an angel to erect a church on the spot. He obeyed the divine command in 309, and gave the building the commemorative name of Edch-Miadzin, or Descended the Only Begotten. In 344 Vagharshapat ceased to be the Armenian capital, and in the 5th century the patriarchal seat was removed to Tovin. The monastery was founded by Narses II., who ruled from 524–33; and a restoration was effected by Gomidas in 618. At length in 1441 the primate George or Kevork brought back the see to the original site, and from that day to the present time Etchmiadzin has been the centre of the Armenian church. In the Russo-Persian war of 1827, though the monastery was declared neutral territory by both belligerents, it was occupied by Russian troops.

ETEOCLES, a mythical king of Thebes, son of Œdipus and Jocasta. He and his brother Polynices were cursed by their father for shutting him up in a prison; and in order to prevent the fulfilment of his prayer that they might engage in fratricidal combat for his throne, they resolved to reign alternately, each for a year. Eteocles as the elder ascended the throne first, but at the expiry of the year he refused to surrender the throne to Polynices. The latter therefore, with the aid of Adrastus, king of Argos, whose daughter he had married, headed the famous expedition of the Seven against Thebes. After a series of unavailing skirmishes between the rival forces, the two brothers met in single combat, and both were slain. The Theban rulers decreed that only Eteocles should receive the honor of burial, and that the body of Polynices should be cast out to the dogs and birds, but notwithstanding the decree, the burial rite was performed to Polynices by his sister Antigone. The fate of Eteocles and Polynices forms the subject of Æschylus's tragedy, *The Seven against Thebes*, and of Euripides's *Phœnissæ*.

ETHELBERT, or ÆTHELBERHT, king of Kent, ascended the throne in 560. In 568 he was defeated by the West Saxons, and his authority limited to Kent, but ultimately he conquered the Saxons of Middlesex and Essex, and about 590 he was acknowledged as over-lord as far north as the Humber. About 575 he married Bertha or Bercta, daughter of the Frankish king Charibert. The Franks had already been converted to Christianity, and when Pope Gregory the Great heard that a Frankish princess was married to the king of Kent, he seized the opportunity to send Augustine to attempt the conversion of the Anglo-Saxons. In 597 Augustine and his companions landed in the Isle of Thanet, and on learning of their arrival Ethelbert, prompted doubtless by Bertha, at once invited them to an interview. Not being certain whether they might not use enchantments against him, he received them, for greater security, in the open air; and after listening to a long sermon from Augustine, he was so far impressed, that although not prepared at once to forsake his old religion, he granted liberty to the monks to preach to his people. According to the accounts that have been handed down their success was almost unprecedented, and as many as 10,000 baptisms are said to have taken place in a single day. Very shortly afterwards Ethelbert gave in his adhesion to Christianity, and immediately all the inhabitants of Kent followed his example. He gave up his palace for the monks to live in, and adjoining it he built a church, on the site of which was afterwards erected the cathedral of Canterbury. He died in 616, and was canonized, his day being the 24th February. The earliest code of Anglo-Saxon laws now extant was issued by Ethelbert in 600. With the exception of a provision for the protection of the property of God and the church, it consists chiefly of enactments against crimes—the various kinds of which, with the penalties attaching to commission of them, are stated in minute detail.

ETHELRED (or ÆTHELRED) II., surnamed the Unready (968–1016), an Anglo-Saxon king, the son of Edgar and Elfrida, was born in 968. On the murder of Edward the Martyr in 979, Ethelred succeeded him on the Anglo-Saxon throne. He is said to have owed his surname "Unready" (*i. e.*, without *rede* or counsel) to Dunstan, who even when he placed the crown on Ethelred's head prophesied that during his reign, on account of the sins of Elfrida, evils should fall upon the English such as they had never yet suffered. Such evils did fall upon them, and were doubtless chiefly due to the king. He possessed considerable energy when roused to exert himself, but it was only exercised fitfully, and generally misdirected, being always a-wanting at critical periods, and never used but to the disadvantage of his kingdom. Careless of everything but his immediate comfort or the gratification of an immediate whim, and listless and fond of ease, he allowed his kingdom and himself to be managed by worthless favorites, whose acts of, as it seems to us, open treachery were not only allowed to pass unpunished, in a manner which appears to us unaccountable, but seemed almost to form steps in their ladder of advancement to special influence and favor with the king. The successes attending the Danish invasions in the reign of Ethelred were due almost wholly to three causes,—the unpreparedness of the Anglo-Saxons, the treachery of the earls, and the failure of the king to follow up victories which were often won with no special preparation and without adequate leaders. About two years after Ethelred mounted the throne the Danish invasions recommenced, but it was not till a later period that their inroads assumed the serious aspect of an attempt to conquer the Anglo-Saxon kingdom. In 988 they were defeated at Watchet in Somersetshire, and in 991 at Maldon, immediately after which latter victory, Ethelred purchased peace from his defeated enemies by money raised through means of the oppressive tax known as the "Danegeld." The Danes were allowed to stay in England, and they on their part agreed to help Ethelred against any other foreign fleet that might attack him; but for some reason now unknown, a dispute arose in 992, and in a battle between the rival fleets, the Anglo-Saxons, notwithstanding the treachery of Elfric, were again victorious. After this the Danes sailed to the north of England and ravaged both sides of the Humber. In 994 Swend, king of the Danes, and Olaf, king of the Norwegians, combined their forces and attacked London, but their attempt was completely frustrated by the valor of the citizens; and they sailed away to accomplish the easier task of ravaging the southern coasts, when Ethelred as usual did nothing to oppose them, but bought them off with a large sum of money. His efforts at conciliation were completely successful with Olaf, who, after being converted to Christianity, and adopted by Ethelred as his son, remained faithful ever afterwards to his promise of friendship. In the years 997, 998, and 999 the Danes ravaged the coasts of Wessex, Sussex, and Kent. In 1000 Ethelred, energetic at the wrong time and for wrong objects, invaded Normandy, but suffered a disastrous defeat. He concluded a treaty with that country soon afterwards, and in 1002 married Emma, daughter of Richard duke of Normandy. In the spring a treaty had been concluded with the Danes, but in the winter of the same year, Ethelred suspecting that they were plotting treachery, ordered a general massacre of all the Danes in England. Among others murdered was Gunold, sister of Swend; and the Danish king, to revenge her death and that of his countrymen, invaded the coast of Devonshire with a large force. He met with scarcely any opposition, and committed the usual ravages till 1007, when peace was concluded by Ethelred's consenting, as at other times, to the payment of a large sum of money. In 1009 Ethelred collected the "largest fleet that had been seen in the reign of any king," but it was soon afterwards nearly wholly destroyed by a violent storm, just before the Danes renewed their invasion. Ethelred, though he had gathered an army, was dissuaded from attacking them by Edric, and afterwards the English, through the treachery of their leaders, suffered a series of defeats; but in 1012 peace was again bought, and Thurkill, one of the Danish leaders, entered the English service. In 1013 Swend, with a more formidable fleet than any he had yet collected, sailed up the Humber, and then marched southward to London; but meeting there with a strenuous resistance, he was compelled to give up the attack and marched to Bath. Here he was proclaimed king, apparently by the Witan, and with the general consent of the English people, who were doubtless wearied of Ethelred's incompetency, of the treachery of the nobles, and of the oppressive taxes which had been paid for no purpose. London itself soon acknowledged the Danish king, and Ethelred, after for a time taking refuge in Thurkill's fleet, escaped to Normandy. Swend died in February, 1014, and on his death Ethelred was recalled by the Witan, on the promise of ruling better in future. In the same year he defeated Cnut, son of Swend, but in 1015 Cnut renewed his attack with a large fleet, and being joined by the traitor Edric, ravaged Wessex and Mercia, and was preparing to attack London, when Ethelred died April 23, 1016. (See Palgrave's *History of the Anglo-Saxons;* Freeman's *Norman Conquest*, vol. i.; and Green's *History of the English People*.)

ETHELWULF, or ÆTHELWULF, an Anglo-Saxon king, succeeded his father Egbert about 836. His reign, like that of his father, was almost wholly occupied with wars against the Danish invaders. For a long time he held them in check, and when in 851 they took Canterbury and London, and defeated Beohrtwulf, king of the Mercians, he met them at Ockley in Surrey, and there "made the greatest slaughter among the heathen army that we have heard tell of unto the present day, and there got the victory." But the Northmen were persevering in their efforts; and it is stated that in 855 they, for the first time, remained over winter in Sheppey. In the same year Ethelwulf made a journey to Rome, accompanied by his youngest and favorite son Alfred, to get the latter consecrated as his successor; and as his first wife Osburga had been for some time dead, he delayed a few months in France to marry Judith, daughter of the king of the Franks. Ethelbald, his eldest surviving son, indignant at his youngest brother being preferred to him as successor to his father's throne, took advantage of his father's absence to stir up a revolution against him, and obtained the support of so powerful a party that an unnatural civil war was only prevented by Ethelwulf agreeing to grant to his son the government of Wessex, he himself being recognized as over-lord, and retaining the rest of the kingdom. He died in 858.

ETHER $(C_2H_5)_2O$, the *Æther* or *Æther Sulphuricus* of pharmacy, is a colorless, volatile, highly inflammable liquid, of specific gravity 0·723, boiling-point when pure 35·6° C, and fusing-point −31° C. It has a strong and characteristic odor, and a hot sweetish taste, is soluble in ten parts of water, and in all proportions in alcohol, and dissolves bromine, iodine, and, in small quantities, sulphur and phosphorus, also the volatile oils, most fatty and resinous substances, gun-cotton (see COLLODION, vol. vi. p. 134), caoutchouc, and certain of the vegetable alkaloids. The vapor mixed with oxygen or air is violently explosive. The making of ether by the action of sulphuric acid on alcohol was known to Raymond Lully, who wrote in the 13th century; and later Basil Valentin and Valerius Cordus described its preparation and properties. The name ether appears to have been applied to the drug only since the times of Froben, who in 1730 termed it *spiritus æthereus.* Ether is manufactured by the distillation of 5 parts of 90 per cent. alcohol with 9 parts of concentrated sulphuric acid, at a temperature of 140°–145° C., a constant stream of alcohol being caused to flow into the mixture during the operation. (See CHEMISTRY, vol. v. p. 491). It is purified by treatment with lime and calcium chloride, and subsequent redistillation. According to P. Stefanelli (*Ber. deutsch. Chem. Ges.*, 1875, p. 439), the presence of as small a quantity as 1 per cent. of alcohol may be detected in ether by the color imparted to it by aniline violet; if water or acetic acid be present, the ether must be shaken with anhydrous potassium carbonate before the application of the test. Ether when drunk has a rapid though evanescent intoxicating effect, estimated to be more than three times that of the same bulk of whiskey, instead of which it is largely consumed in some parts of Ireland. (See H. N. Draper, *Med. Press and Circular*, iv. 117.) Mixed with twice its volume of rectified spirit, it is administered internally as a remedy for nervous headache, flatulence, hiccough, hysteria, and spasmodic vomiting and asthma, occasionally also in angina pectoris, intermittent fevers and typhus, and as an antidote for narcotic poisons, and for relieving the pain caused by biliary calculi. It has been shown by Longet that ether when swallowed even in fatal doses does not at any time produce anæsthesia. Much heat being rendered latent by its evaporation, ether is sometimes employed as a refrigerant in the reduction of hernia. By the use of Dr. Richardson's ether spray apparatus for effecting local anæsthesia, a temperature of −6° F. can be obtained. When not allowed to evaporate, ether acts as a rubefacient. Its vapor when inhaled causes at first considerable irritation of the air-passages, and increased rapidity of the pulse, accompanied by much excitement. With the establishment of complete anæsthesia the pulse sinks to 60° or 70°, the face becomes pallid, and the muscles are relaxed. Ether occasions more excitement, and requires a somewhat longer period for its exhibition than chloroform, but does not exercise upon the heart the sedative influence of that drug. A history of the employment of ether as an anæsthetic will be found under ANÆSTHESIA, vol. i. p. 692. See also CHLOROFORM, vol. v. p. 590.

ETHER, or ÆTHER (*αἰθήρ*, probably from *αἴθω*, I burn, though Plato in his *Cratylus* (410, b) derives the name from its perpetual motion—*ὅτι ἀεὶ θεῖ περὶ τὸν ἀέρα ῥέων, ἀειθεὴρ δικαίως ἂν καλοῖτο*), a material substance of a more subtle kind than visible bodies, supposed to exist in those parts of space which are apparently empty.

The hypothesis of an æther has been maintained by different speculators for very different reasons. To those who maintained the existence of a plenum as a philosophical principle, nature's abhorrence of a vacuum was a sufficient reason for imagining an all-surrounding æther, even though every other argument should be against it. To Descartes, who made extension the sole essential property of matter, and matter a necessary condition of extension, the bare existence of bodies apparently at a distance was a proof of the existence of a continuous medium between them.

But besides these high metaphysical necessities for a medium, there were more mundane uses to be fulfilled by æthers. Æthers were invented for the planets to swim in, to constitute electric atmospheres and magnetic effluvia, to convey sensations from one part of our bodies to another, and so on, till all space had been filled three or four times over with æthers. It is only when we remember the extensive and mischievous influence on science which hypotheses about æthers used formerly to exercise, that we can appreciate the horror of æthers which sober-minded men had during the 18th century, and which, probably as a sort of hereditary prejudice, descended even to the late Mr. John Stuart Mill.

The disciples of Newton maintained that in the fact of the mutual gravitation of the heavenly bodies, according to Newton's law, they had a complete quantitative account of their motions; and they endeavored to follow out the path which Newton had opened up by investigating and measuring the attractions and repulsions of electrified and magnetic bodies, and the cohesive forces in the interior of bodies, without attempting to account for these forces.

Newton himself, however, endeavored to account for gravitation by differences of pressure in an æther (see art. ATTRACTION, vol. iii. p. 56); but he did not publish his theory, "because he was not able from experiment and observation to give a satisfactory account of this medium, and the manner of its operation in producing the chief phenomena of nature."

On the other hand, those who imagined æthers in order to explain phenomena could not specify the nature of the motion of these media, and could not prove that the media, as imagined by them, would produce the effects they were meant to explain. The only æther which has survived is that which was invented by Huygens to explain the propagation of light. The evidence for the existence of the luminiferous æther has accumulated as additional phenomena of light and other radiations have been discovered; and the properties of this medium, as deduced from the phenomena of light, have been found to be precisely those required to explain electro-magnetic phenomena.

Function of the æther in the propagation of radiation.—The evidence for the undulatory theory of light will be given in full under the article on LIGHT, but we may here give a brief summary of it so far as it bears on the existence of the æther.

That light is not itself a substance may be proved from the phenomenon of interference. A beam of light from a single source is divided by certain optical methods into two parts, and these, after travelling by different paths, are made to reunite and fall upon a screen. If either half of the beam is stopped, the other falls on the screen and illuminates it, but if both are allowed to pass, the screen in certain places becomes dark, and thus shows that the two portions of light have destroyed each other.

Now, we cannot suppose that two bodies when put together can annihilate each other; therefore light cannot be a substance. What we have proved is that one portion of light can be the exact opposite of another portion, just as $+a$ is the exact opposite of $-a$, whatever a may be. Among physical quantities we find some which are capable of having their signs reversed, and others which are not. Thus a displacement in one direction is the exact opposite of an equal displacement in the opposite direction. Such quantities are the measures, not of substances, but always of processes taking place in a substance. We therefore conclude that light is not a substance, but a process going on in a substance, the process going on in the first portion of light being always the exact opposite of the process going on in the other at the same instant, so that when the two portions are combined no process goes on at all. To determine the nature of the process in which the radiation of light consists, we alter the length of the path of one or both of the two portions of the beam, and we find that the light is extinguished when the difference of the length of the paths is an odd multiple of a certain small distance called a half wave-length. In all other cases there is more or less light; and when the paths are equal, or when their difference is a multiple of a whole wave-length, the screen appears four times as bright as when one portion of the beam falls on it. In the ordinary form of the experiment these different cases are exhibited simultaneously at different points of the screen, so that we see on the screen a set of fringes consisting of dark lines at equal intervals, with bright bands of graduated intensity between them.

If we consider what is going on at different points in the axis of a beam of light at the same instant, we shall find that if the distance between the points is a multiple of a wave-length the same process is going on at the two points at the same instant, but if the distance is an odd multiple of half a wave-length the process going on at one point is the exact opposite of the process going on at the other.

Now, light is known to be propagated with a certain velocity ($3\cdot004 \times 10^{10}$ centimetres per second in vacuum, according to Cornu). If, therefore, we suppose a movable point to travel along the ray with this velocity, we shall find the same process going on at every point of the ray as the moving point reaches it. If, lastly, we consider a fixed point in the axis of the beam, we shall observe a rapid alternation of these opposite processes, the interval of time between similar processes being the time light takes to travel a wave-length.

These phenomena may be summed up in the mathematical expression

$$u = A \cos (nt - px + a),$$

which gives u, the phase of the process, at a point whose distance measured from a fixed point in the beam is x, and at a time t.

We have determined nothing as to the nature of the process. It may be a displacement, or a rotation, or an electrical disturbance, or indeed any physical quantity which is capable of assuming negative as well as positive values. Whatever be the nature of the process, if it is capable of being expressed by an equation of this form, the process going on at a fixed point is called a *vibration;* the constant A is called the *amplitude;* the time $\frac{2\pi}{n}$ is called the *period;* and $nt - px + a$ is the *phase.*

The configuration at a given instant is called a *wave,* and the distance $\frac{2\pi}{p}$ is called the *wave-length.* The velocity of progression is $\frac{n}{p}$. When we contemplate the different parts of the medium as going through the same process in succession, we use the word undulatory to denote this character of the process without in any way restricting its physical nature.

A further insight into the physical nature of the process is obtained from the fact that if the two rays are polarized, and if the plane of polarization of one of them be made to turn round the axis of the ray, then when the two planes of polarization are parallel the phenomena of interference appear as above described. As the plane turns round, the dark and light bands become less distinct, and when the planes of polarization are at right angles, the illumination of the screen becomes uniform, and no trace of interference can be discovered.

Hence the physical process involved in the propagation of light must not only be a directed quantity or vector capable of having its direction reversed, but this vector must be at right angles to the ray, and either in the plane of polarization or perpendicular to it. Fresnel supposed it to be a displacement of the medium perpendicular to the plane of polarization. Maccullagh and Neumann supposed it to be a displacement in the plane of polarization. The comparison of these two theories must be deferred till we come to the phenomena of dense media.

The process may, however, be an electro-magnetic one, and as in this case the electric displacement and the magnetic disturbance are perpendicular to each other, either of these may be supposed to be in the plane of polarization.

All that has been said with respect to the radiations which affect our eyes, and which we call light, applies also to those radiations which do not produce a luminous impression on our eyes, for the phenomena of interference have been observed, and the wave-lengths measured, in the case of radiations which can be detected only by their heating or by their chemical effects.

Elasticity, tenacity, and density of the æther.—Having so far determined the geometrical character of the process, we must now turn our attention to the medium in which it takes place. We may use the term æther to denote this medium, whatever it may be.

In the first place, it is capable of transmitting energy. The radiations which it transmits are able not only to act on our senses, which of itself is evidence of work done, but to heat bodies which absorb them; and by measuring the heat communicated to such bodies, the energy of the radiation may be calculated.

In the next place this energy is not transmitted instantaneously from the radiating body to the absorbing body, but exists for a certain time in the medium.

If we adopt either Fresnel's or Maccullagh's form of the undulatory theory, half of this energy is in the form of potential energy, due to the distortion of elementary portions of the medium, and half in the form of kinetic energy, due to the motion of the medium. We must therefore regard the æther as possessing elasticity similar to that of a solid body, and also as having a finite density. If we take Pouillet's estimate of 1·7633 as the number of gramme-centigrade units of heat produced by direct sunlight falling on a square centimetre in a minute, this is equivalent to $1{\cdot}234\times10^6$ ergs per second. Dividing this by $3{\cdot}004\times10^{10}$, the velocity of light in centimetres per second, we get for the energy in a cubic centimetre $4{\cdot}1\times10^{-5}$ ergs. Near the sun the energy in a cubic centimetre would be about 46,000 times this, or 1·886 ergs. If we further assume, with Sir W. Thomson, that the amplitude is not more than one-hundredth of the wave-length, we have $Ap=\frac{2\pi}{100}$, or about $\frac{1}{16}$; so that we have—

Energy per cubic centimetre $=\frac{1}{2}\rho V^2A^2p^2=$ 1·886 ergs.
Greatest tangential stress per square centimetre, $=\rho V^2Ap = 30{\cdot}176$ dynes.
Coefficient of rigidity of æther, . . . $=\rho V^2 = 842{\cdot}8$.
Density of æther, . . $=\rho = 9.36\times10^{-19}$.

The coefficient of rigidity of steel is about 8×10^{11}, and that of glass $2{\cdot}4\times10^{11}$.

If the temperature of the atmosphere were everywhere 0° C, and if it were in equilibrium about the earth supposed at rest, its density at an infinite distance from the earth would be 3×10^{-346} which is about 3×10^{327} times less than the estimated density of the æther. In the regions of interplanetary space the density of the æther is therefore very great compared with that of the attenuated atmosphere of interplanetary space, but the whole mass of æther within a sphere whose radius is that of the most distant planet is very small compared with that of the planets themselves.[1]

The æther distinct from gross matter.—When light travels through the atmosphere it is manifest that the medium through which the light is propagated is not the air itself, for in the first place the air cannot transmit transverse vibrations, and the normal vibrations which the air does transmit travel about a million times slower than light. Solid transparent bodies, such as glass and crystals, are no doubt capable of transmitting transverse vibrations, but the velocity of transmission is still hundreds of thousand times less than that with which light is transmitted through these bodies. We are therefore obliged to suppose that the medium through which light is propagated is something distinct from the transparent medium known to us, though it interpenetrates all transparent bodies and probably opaque bodies too.

The velocity of light, however, is different in different transparent media, and we must therefore suppose that these media take some part in the process, and that their particles are vibrating as well as those of the æther, but the energy of the vibrations of the gross particles must be very much smaller than that of the æther, for otherwise a much larger proportion of the incident light would be reflected when a ray passes from vacuum to glass or from glass to vacuum than we find to be the case.

Relative motion of the æther.—We must therefore consider the æther within dense bodies as somewhat loosely connected with the dense bodies, and we have next to inquire whether, when these dense bodies are in motion through the great ocean of æther they carry along with them the æther they contain, or whether the æther passes through them as the water of the sea passes through the meshes of a net when it is towed along by a boat. If it were possible to determine the velocity of light by observing the time it takes to travel between one station and another on the earth's surface, we might, by comparing the observed velocities in opposite directions, determine the velocity of the æther with respect to these terrestrial stations. All methods, however, by which it is practicable to determine the velocity of light from terrestrial experiments depend on the measurement of the time required for the double journey from one station to the other and back again, and the increase of this time on account of a relative velocity of the æther equal to that of the earth in its orbit would be only about one hundred millionth part of the whole time of transmission, and would therefore be quite insensible.

The theory of the motion of the æther is hardly sufficiently developed to enable us to form a strict mathematical theory of the aberration of light, taking into account the motion of the æther. Professor Stokes, however, has shown that, on a very probable hypothesis with respect to the motion of the æther, the amount of aberration would not be sensibly affected by that motion.

The only practicable method of determining directly the relative velocity of the æther with respect to the solar system is to compare the values of the velocity of light deduced from the observation of the eclipses of Jupiter's satellites when Jupiter is seen from the earth at nearly opposite points of the ecliptic.

Arago proposed to compare the deviation produced in the light of a star after passing through an achromatic prism when the direction of the ray within the prism formed different angles with the direction of motion of the earth in its orbit. If the æther were moving swiftly through the prism, the deviation might be expected to be different when the direction of the light was the same as that of the æther, and when these directions were opposite.

The present writer[2] arranged the experiment in a more practicable manner by using an ordinary spectroscope, in which a plain mirror was substituted for the slit of the collimator. The cross wires of the observing telescope were illuminated. The light from any point of the wire passed through the object-glass and then through the prisms as a parallel pencil till it fell on the object-glass of the collimator, and came to a focus at the mirror, where it was reflected, and after passing again through the object-glass it formed a pencil passing through each of the prisms parallel to its original direction, so that the object-glass of the observing telescope brought it to a focus coinciding with the point of the cross wires from which it originally proceeded. Since the image coincided with the object, it could not be observed directly, but by diverting the pencil by partial reflection at a plane surface of glass, it was found that the image of the finest spider line could be distinctly seen, though the light which formed the image had passed twice through three prisms of 60°. The apparatus was first turned so that the direction of the light in first passing through the second prism was that of the earth's motion in its orbit. The apparatus was afterwards placed so that the direction of the light was opposite to that of the earth's motion. If the deviation of the ray by the prisms was increased or diminished for this reason in the first journey, it would be diminished or increased in the return journey, and the image would appear on one side of the object. When the apparatus was turned round it would appear on the other side. The experiment was tried at different times of the year, but only negative results were obtained. We cannot, however, conclude absolutely from this experiment that the æther near the surface of the earth is carried along with the earth in its orbit, for it has been shown by Professor Stokes[1] that according to Fresnel's hypothesis the relative velocity of the æther within the prism would be to that of the æther outside inversely as the square of the index of refraction, and that in this case the deviation would not be sensibly altered on account of the motion of the prism through the æther.

[1] See Sir W. Thomson, *Trans. R. S. Edin.*, vol. xxi. p. 60.

[2] *Phil. Trans.*, clviii. (1868), p. 532.

Fizeau,[2] however, by observing the change of the plane of polarization of light transmitted obliquely through a series of glass plates, obtained what he supposed to be evidence of a difference in the result when the direction of the ray in space was different, and Angström obtained analogous results by diffraction. The writer is not aware that either of these very difficult experiments has been verified by repetition.

In another experiment of M. Fizeau, which seems entitled to greater confidence, he has observed that the propogation of light in a stream of water takes place with greater velocity in the direction in which the water moves than in the opposite direction, but that the change of velocity is less than that which would be due to the actual velocity of the water, and that the phenomenon does not occur when air is substituted for water. This experiment seems rather to verify Fresnel's theory of the æther; but the whole question of the state of the luminiferous medium near the earth, and of its connection with gross matter, is very far as yet from being settled by experiment.

Function of the æther in electro-magnetic phenomena.—Faraday conjectured that the same medium which is concerned in the propagation of light might also be the agent in electro-magnetic phenomena. "For my own part," he says, "considering the relation of a vacuum to the magnetic force, and the general character of magnetic phenomena external to the magnet, I am much more inclined to the notion that in the transmission of the force there is such an action, external to the magnet, than that the effects are merely attraction and repulsion at a distance. Such an action may be a function of the æther; for it is not unlikely that, if there be an æther, it should have other uses than simply the conveyance of radiation."[3] This conjecture has only been strengthened by subsequent investigations.

Electrical energy is of two kinds, electro-static and electrokinetic. We have reason to believe that the former depends on a property of the medium in virtue of which an electric displacement elicits an electro-motive force in the opposite direction, the electro-motive force for unit displacement being inversely as the specific inductive capacity of the medium.

The electro-kinetic energy, on the other hand, is simply the energy of the motion set up in the medium by electric currents and magnets, this motion not being confined to the wires which carry the currents, or to the magnet, but existing in every place where magnetic force can be found.

Electro-magnetic Theory of Light.—The properties of the electro-magnetic medium are therefore as far as we have gone similar to those of the luminiferous medium, but the best way to compare them is to determine the velocity with which an electro-magnetic disturbance would be propagated through the medium. If this should be equal to the velocity of light, we would have strong reason to believe that the two media, occupying as they do the same space, are really identical. The data for making the calculation are furnished by the experiments made in order to compare the electromagnetic with the electro-static system of units. The velocity of propagation of an electro-magnetic disturbance in air, as calculated from different sets of data, does not differ more from the velocity of light in air, as determined by different observers, than the several calculated values of these quantities differ among each other.

If the velocity of propagation of an electro-magnetic disturbance is equal to that of light in other transparent media, then in non-magnetic media the specific inductive capacity should be equal to the square of the index of refraction.

Boltzmann[4] has found that this is very accurately true for the gases which he has examined. Liquids and solids exhibit a greater divergence from this relation, but we can hardly expect even an approximate verification when we have to compare the results of our sluggish electrical experiments with the alternations of light, which take place billions of times in a second.

The undulatory theory, in the form which treats the phenomena of light as the motion of an elastic solid, is still encumbered with several difficulties.[5]

The first and most important of these is that the theory indicates the possibility of undulations consisting of vibrations normal to the surface of the wave. The only way of accounting for the fact that the optical phenomena which would arise from these waves do not take place is to assume that the æther is incompressible.

The next is that, whereas the phenomena of reflection are best explained on the hypothesis that the vibrations are perpendicular to the plane of polarization, those of double refraction require us to assume that the vibrations are in that plane.

The third is that, in order to account for the fact that in a doubly refracting crystal the velocity of rays in any principal plane and polarized in that plane is the same, we must assume certain highly artificial relations among the coefficients of elasticity.

The electro-magnetic theory of light satisfies all these requirements by the single hypothesis[6] that the electric displacement is perpendicular to the plane of polarization. No normal displacement can exist, and in doubly refracting crystals the specific di-electric capacity for each principal axis is assumed to be equal to the square of the index of refraction of a ray perpendicular to that axis, and polarized in a plane perpendicular to that axis. Boltzmann[7] has found that these relations are approximately true in the case of crystallized sulphur, a body having three unequal axes. The specific di-electric capacities for these axes are respectively

4·773 3·970 3·811,

and the squares of the indices of refraction

4·576 3·886 3·591

Physical constitution of the æther.—What is the ultimate constitution of the æther? Is it molecular or continuous?

We know that the æther transmits transverse vibrations to very great distances without sensible loss of energy by dissipation. A molecular medium, moving under such conditions that a group of molecules once near together remain near each other during the whole motion, may be capable of transmitting vibrations without much dissipation of energy, but if the motion is such that the groups of molecules are not merely slightly altered in configuration but entirely broken up, so that their component molecules pass into new types of grouping, then in the passage from one type of grouping to another the energy of regular vibrations will be frittered away into that of the irregular agitation which we call heat.

We cannot therefore suppose the constitution of the æther to be like that of a gas, in which the molecules are always in a state of irregular agitation, for in such a medium a transverse undulation is reduced to less than one five-hundreth of its amplitude in a single wave-length. If the æther is molecular, the grouping of the molecules must remain of the same type, the configuration of the groups being only slightly altered during the motion.

Mr. S. Tolver Preston[8] has supposed that the æther is like a gas whose molecules very rarely interfere with each other, so that their mean path is far greater than any planetary distances. He has not investigated the properties of such a medium with any degree of completeness, but it is easy to see that we might form a theory in which the molecules *never* interfere with each other's motion of translation, but travel in all directions with the velocity of light; and if we further suppose that vibrating bodies have the power of impressing on these molecules some vector property (such as rotation about an axis) which does not interfere with their motion of translation, and which is then carried along by the molecules, and if the alternation of the average value of this vector for all the molecules within an element of volume be the process which we call light, then the equations which express this average will be of the same form as that which expresses the displacement in the ordinary theory.

It is often asserted that the mere fact that a medium is elastic or compressible is a proof that the medium is not continuous, but is composed of separate parts having void spaces between them. But there is nothing inconsistent with experience in supposing elasticity or compressibility to be properties of every portion, however small, into which the medium can be conceived to be divided, in which case the medium would be strictly continuous. A medium, however, though homogeneous and continuous as regards its density, may be rendered heterogeneous by its motion, as in Sir W. Thomson's hypothesis of vortex-molecules in a perfect liquid (see art. ATOM).

The æther, if it is the medium of electro-magnetic phenomena, is probably molecular, at least in this sense.

Sir W. Thomson[1] has shown that the magnetic influence on light discovered by Faraday depends on the direction of motion of moving particles, and that it indicates a rotational motion in the medium when magnetized. See also *Maxwell's Electricity and Magnetism*, art. 806, etc.

Now, it is manifest that this rotation cannot be that of the medium as a whole about an axis, for the magnetic field may be of any breadth, and there is no evidence of any motion the velocity of which increases with the distance from a single fixed line in the field. If there is any motion of rotation, it must be a rotation of very small portions of the medium each about its own axis, so that the medium must be broken up into a number of molecular vortices.

We have as yet no data from which to determine the size of the number of these molecular vortices. We know, however, that the magnetic force in the region in the neighborhood of a magnet is maintained as long as the steel retains its magnetization, and as we have no reason to believe that a steel magnet would lose all its magnetization by the mere lapse of time, we conclude that the molecular vortices do not require a continual expenditure of work in order to maintain their motion, and that therefore this motion does not necessarily involve dissipation of energy.

No theory of the constitution of the æther has yet been invented which will account for such a system of molecular vortices being maintained for an indefinite time without their energy being gradually dissipated into that irregular agitation of the medium which, in ordinary media, is called heat.

Whatever difficulties we may have in forming a consistent idea of the constitution of the æther, there can be no doubt that the interplanetary and interstellar spaces are not empty, but are occupied by a material substance or body, which is certainly the largest, and probably the most uniform, body of which we have any knowledge.

Whether this vast homogeneous expanse of isotropic matter is fitted not only to be a medium of physical interaction between distant bodies, and to fulfil other physical functions of which, perhaps, we have as yet no conception, but also, as the authors of the *Unseen Universe* seem to suggest, to constitute the material organism of beings exercising functions of life and mind as high as or higher than ours are at present, is a question far transcending the limits of physical speculation. (J. C. M.)

ETHEREDGE, SIR GEORGE (*c.* 1636–1689), an English dramatist, was born in or near London about the year 1636. He was a scion of an ancient and distinguished family of Oxfordshire. He was educated at Cambridge, but left the university early to travel in France and Flanders. It is probable that he witnessed in Paris the performances of some of Molière's earliest comedies; and he seems from an allusion in one of his plays, to have been personally acquainted with Bussy Rabutin. On his return to London he studied the law at one of the Inns of Court. His tastes were those of a fine gentleman, and he indulged freely in pleasure. Some time soon after the Restoration he composed his comedy of *The Comical Revenge, or Love in a Tub*, which introduced him to Lord Buckhurst, afterwards the earl of Dorset. This was brought out at the Duke's Theatre in 1664, and a few copies were printed in the same year. The main edition of this play, however, was not issued until 1669. It is partly in rhymed heroic verse, like the stilted tragedies of the Howards and Killigrews, but it contains comic scenes that are exceedingly bright and fresh. The sparring between Sir Frederick and the Widow introduced a style of wit hitherto unknown upon the English stage. The success of this play was very great, but Etheredge waited four years before he repeated his experiment. Meanwhile he gained the highest reputation as a poetical beau, and moved in the circle of Sir Charles Sedley, Lord Rochester, and the other noble wits of the day. In 1668 he brought out *She would if she could*, a comedy in many respects admirable, full of action, wit, and spirit, but to the last degree frivolous and immoral. But in this play Etheredge first shows himself a new power in literature; he has nothing of the rudeness of his predecessors or the grossness of his contemporaries. We move in an airy and fantastic world, where flirtation is the only serious business of life. At this time Etheredge was living a life no less frivolous and unprincipled than those of his Courtals and Freemans. He formed an alliance with the famous actress Mrs. Barry; she bore him a daughter, on whom he settled £6000, but who unhappily died in her youth. His wealth and wit, the distinction and charm of his manners, won him the general worship of society, and his temperament is best shown by the names his contemporaries gave him, of "gentle George" and "easy Etheredge." The age upbraided him for inattention to literature; and at last, after a silence of eight years, he came forward with one more play, unfortunately his last. *The Man of Mode, or Sir Fopling Flutter*, indisputably the best comedy of intrigue written in England before the days of Congreve, was acted and printed in 1676, and had an unbounded success. Besides the merit of its plot and wit, it had the personal charm of being supposed to satirize, or at least to paint, persons well known in London. Sir Fopling Flutter was a portrait of Beau Hewit, the reigning exquisite of the hour; in Dorimant the poet drew the elegant Sir Charles Sedley, and in Medley a portrait of himself; while even the drunken shoemaker was a real character, who made his fortune from being thus brought into public notice. After this brilliant success Etheredge retired from literature; his gallantries and his gambling in a few years deprived him of his fortune, and he looked about for a rich match. In 1683 he met with a wealthy elderly widow, who consented to marry him if he made a lady of her. He accordingly got himself knighted, and gained her hand and her money. It is said that before this, about 1680, he had been sent on an embassy to Turkey; it is certain that in 1686 he was appointed resident minister in the Imperial German Court at Ratisbon. He was very uncomfortable in Germany, and solaced himself by writing amusing epistles in prose and verse to his friends in England. In 1688 he published a prose *Account of the rejoicing at the Diet of Ratisbon.* In 1689 he is believed to have died in Ratisbon in a tragical manner, for whilst conducting a party of friends to the stairs after a banquet at his house, he fell over into the court below and broke his neck. But his death occurred at the moment when England was convulsed with revolution, and no one has preserved the exact date of it.

Etheredge deserves to hold a more distinguished place in our literature than has generally been allotted to him. In a dull and heavy age, he inaugurated a period of genuine wit and sprightliness. He invented the comedy of intrigue, and led the way for the masterpieces of Congreve and Sheridan. Before his time the manner of Ben Jonson had prevailed in comedy, and traditional "humors" and typical eccentricities, instead of real characters, had crowded the comic stage. Etheredge paints with a light faint hand, but it is from nature, and his portraits of fops and beaux are simply unexcelled. No one knows better than he how to present a gay young gentleman, a Dorimant, "an unconfinable rover after amorous adventures." His genius is as light as thistledown; he is frivolous, without force of conviction, without principle; but his wit is very sparkling, and his style pure and singularly picturesque. No one approaches Etheredge in delicate touches of dress, furniture, and scene; he makes the fine airs of London gentlemen and ladies live before our eyes even more vividly than Congreve does; but he has less insight and less energy than Congreve. Had he been poor or ambitious he might have been to England almost what Molière was to France, but he was a rich man living at his ease, and he disdained to excel in literature. Etheredge was "a fair, slender, genteel man, but spoiled his countenance with drinking." His contemporaries all agree in acknowledging that he was the soul of affability and sprightly good-nature.

---

[1] *Proceedings of the Royal Society*, June, 1856.

There is no recent edition of the works of Sir George Etheredge. A critical collection of them would fill a very important gap in our literature.

ETHERIDGE, John Wesley (1804–1866), a Wesleyan minister, and a writer on church history and biblical literature, was born near Newport, Isle of Wight, 24th February, 1804. He received most of his early education from his father, who was master of an academy at Portsea, which was afterwards removed to Newport. Though he never attended any university he acquired ultimately a thorough knowledge of Greek, Latin, Hebrew, Syriac, French, and German. In 1824 he was placed on the plan as a local preacher. In 1826 his offer to enter the ministry was accepted, and after probationary trial at Hull, Bingley, Lambeth, and Brighton, he was received into full connection at the conference of 1831. For two years after this he remained at Brighton, and in 1833 he removed to Cornwall, being stationed successively at the Truro and Falmouth circuits. From Falmouth he removed to Darlaston, where in 1838 his health gave way. For a good many years he was a supernumerary, and in 1843 he took up his residence at Paris, where in the public libraries he found great facilities for prosecuting his favorite studies. His health having considerably improved, he, in 1843, became pastor of the Methodist church at Boulogne. He returned to England in 1847, and was appointed successively to the circuits of Islington, Bristol, Leeds, Penzance, Penryn, Truro, and St. Anstell in East Cornwall. Shortly after his return to England he received the degrees of M.A. and Ph.D. from the university of Heidelberg. He died at Camborne, May 24, 1866.

His principal works are *Horæ Aramaicæ* (1843); *History of the Syrian Churches* (1847); *The Apostolic Acts and Epistles, from the Peshito or Ancient Syriac* (1849); *Jerusalem and Tiberias, a Survey of the Religious and Scholastic Learning of the Jews* (1856); *The Targums of Onkelos and Jonathan ben Uzziel* (1st vol. in 1862, 2d in 1865). See *Memoir*, by Rev. Thornley Smith (1871).

ETHICS. I. Definition and General Account of the Subject.—It is not easy to define in a single phrase the subject commonly called Ethics in such a manner as to meet with general acceptance; as its boundaries and relations to cognate subjects are variously conceived by writers of different schools, and rather indefinitely by mankind in general. Nor does the derivation of the term help us much. Ethics (ἠθικά) originally meant that which relates to ἦθος ("character"); the treatise of Aristotle's, however, to which the term was first applied, is not concerned with character considered simply as character, but with its good and bad qualities. Indeed, the antithesis of "good" and "bad," in some form, is involved in all ethical affirmation; and its presence constitutes a fundamental distinction between the science or study of ethics and any department of physical inquiry. Physics is concerned with what is, has been, or will be; ethics with what is "good," or what "ought to be," and its opposite. We must add, however, that the good that ethics investigates is "good for man," to distinguish it from universal or absolute good, which is the subject-matter of theology or ontology; and again, if we are to separate ethics from politics, we must introduce a further qualification, and define the former as the study of the Good or Well-being of men considered as individuals. Neither of these distinctions, however, should be taken to imply a complete division of subjects; and neither, it may be added, was reached at once and without effort in the development of ethical reflection. In Platonism we find Ethics and Ontology indissolubly blended; and, indeed, in almost every philosophical system in which the universe is contemplated as having an ultimate end or Good, the good of human beings is conceived as somehow closely related to this Universal Good. So again the connection between Ethics and Politics is naturally very intimate. We only know the individual man as a member of some society; what we call his virtues are chiefly exhibited in his dealings with his fellows, and his most prominent pleasures are derived from intercourse with them; thus it is a paradox to maintain that man's highest good is independent of his social relations, or of the constitution and condition of the community of which he forms a part. So, again, it would be generally admitted that a statesman ought to aim at promoting the well-being of his fellow citizens considered as individuals; and if so, the investigation of the particulars of such well-being must be an integral part of politics. Still it is manifest that the good of an individual man can be separated as an object of study from the good of his community; so that the ethical point of view has to be distinguished from the political, however large a field the two studies may have in common.

When, however, we thus isolate in thought the individual man from his polity, the close connection of Ethics with Psychology becomes manifest. It is plain that the chief good of man cannot consist in anything external and material, such as wealth; nor even in mere bodily health and well-being, which experience shows to be compatible with extreme badness and wretchedness. And though it is perhaps true that goodness is commonly attributed to men from a consideration of the external effects of their conduct; still it is generally held that a certain state of the agent's mind, a certain quality of disposition, motive, intention, or purpose, is essential to the perfect moral goodness of an action. Thus all (or almost all) ethical schools would agree that the main object of their investigation must belong to the psychical side of human life; whether they hold that ultimate good is to be found in psychical existence regarded as merely sentient and emotional, identifying it with some species of desirable feeling or pleasure, or the genus or sum of such feelings, or whether they rather maintain that well-being of the mind must lie solely or chiefly in the quality of its activity. And when we attempt to work out either view into a clear and complete system, we are led inevitably to further psychological study, in order to examine different kinds and degrees of pleasure and pain, determine the nature and mutual relations of the different virtues or good qualities of character, and their opposites. So again, in discussing the fundamental question as to what is ultimately good or desirable, moralists are led to observe carefully what men actually do desire and aim at, and thus to analyze fully the process of voluntary action, as well as the emotional states that precede and prompt to it. In fact it will appear that all important ethical notions are also psychological; except the fundamental antithesis of "good" and "bad," or "right" and "wrong," with which psychology is not primarily concerned, any more than physics.

The two antitheses just mentioned are frequently regarded as identical. And in fact it does not matter for ordinary purposes whether we speak of "right" or "good" conduct, "wrong" or "bad" motives. The common notion of what is Good for a human being—even if we restrict it to what is "ultimately" good, or "good in itself" and not merely as a means to some further end—includes more than the common notion of what is Right for him, or his Duty. No doubt it is commonly believed that it will be ultimately best for a man to do his duty, and that this will promote his real Interest or Happiness; but it does not follow that the notions of duty and interest are to be identified, or even that the connection between the two may be scientifically demonstrated. The connection is often regarded rather as a matter of faith; indeed many would hold that it is not undesirable that it should be somewhat obscure, in order that duty may be done as duty, and not from a mere calculation of self-love. Thus we arrive at another conception of ethics, in which it is viewed as concerned primarily with the principles of duty or the moral code, and only secondarily—or perhaps not at all—with the relation of duty to the agent's private happiness. On this view the study connects itself with theology, if the rules of duty are regarded as a code of divine legislation; and apart from this reference it has a close affinity to rational or abstract jurisprudence. We might distinguish this as the modern view of ethics in contrast with the former, which was that of ancient Greek philosophy generally[1]—the transition between the two being due chiefly to the influence of Christianity, but partly also to that of Roman jurisprudence. It is true that the thought of "the gods' unwritten and unfaltering law" was not by any means absent from the moral reflection of Greece: still, the idea of Law was not taken as the ultimate and fundamental notion in any of the ancient ethical systems. These all proceed on the assumption that man, as a reasonable being, must seek his own highest good in this earthly life, and therefore that any laws he has to obey must be demonstrated to be means to the attainment of this good, or particulars in which it is realized. On this point the change produced by Christianity is even more striking, if we consider its more general effects rather than its influence on the minds that were most completely penetrated by its religious spirit. The true Christian saint lived even on earth, no less than the pagan philosopher, a life which he regarded as intrinsically preferable to all other modes of earthly existence; and, like the Platonic philosopher, a life of which practical virtue was not so much the essence as the outward expression. Still even for the saint this earthly life afforded but an imperfect foretaste of the bliss for which he hoped; and in the view of more ordinary Christians, the ultimate good of man vanished from the scrutiny of mere ethical speculation into the indefinite brightness of a future life of happiness, supernaturally bestowed by God as a reward for obedience to his laws. Or rather, perhaps, by the mass of Christians, the moral code was more commonly regarded, in still closer analogy to human legislation, as supported by penal sanctions; since in all ages of Christianity the fear of the pains of hell has probably been a more powerful motive to draw men from vice than the hope of the pleasures of heaven. On either view the ultimate weal or ill of human beings became something that might be imagined and rhetorically described, but not definitely known or scientifically investigated: and thus the subject-matter of ethics defined itself afresh as Moral Law, a body of rules absolutely prescribed, and supplying a complete guidance for human conduct, though not claiming to contain an exhaustive statement of human good.

---

[1] To this statement a partial exception must be made as regards Stoicism, through which, in fact, as will presently appear, the transition was partly made from the ancient to the modern manner of thought.

Within the Christian church, through the early and middle ages of its history, it naturally fell to theologians to expound and to priests to administer this code of divine legislation. But when a more philosophical treatment of ethics was introduced by the schoolmen, the combination in the code of two elements, one distinctively Christian, and the other cognizable by natural reason and binding on all men apart from revelation, began to be clearly seen; and an adequate theory of this second element seemed to be supplied by the development of theoretical jurisprudence that followed on the revival, in the 12th century, of the study of Roman law. In the later treatment of legal principles in Rome, the notion of a law of nature had become prominent; and this notion was naturally and easily adapted to represent the element in morality that was independent of revelation. It is true that the natural law of the philosophical jurists did not concern itself primarily with duties, but rather with rights, and so with the relative and negative duties that are involved in the notion of rights; hence it could not properly be identified with more than a portion of the moral code. This portion, however, is of such fundamental importance that the difference we have noticed has been frequently overlooked, and Morality not distinguished from Natural Law, except by the further control that the former claims over the inner springs of voluntary action.

It is chiefly in connection with this jural view of morality that the inquiry into the origin of the moral faculty has occupied a prominent place in the modern treatment of Ethics. So long as the "moral faculty" is regarded merely as the faculty of knowing our true good, together with its main causes or conditions, it hardly seems important to inquire how this faculty originated, any more than it is for a geometer to investigate the origin of the spatial faculty. But when conscience is conceived as a legislator and governor within the breast, claiming absolute authority over all other impulses, it is natural that the legitimacy of its claim should be investigated; and it is not hard to understand how this legitimacy is thought to depend on the "originality" of the faculty—that is, on its being a part of the plan or type according to which human nature was originally constructed. Hence investigations into the moral condition of children and savages, and even animals, and more or less conjectural theories of the soul's growth and development, have been commonly regarded as necessary appendages or introductions to modern ethical discussion.

So, again, it is through the jural conception of ethics that the controversy on free will chiefly becomes important. A man does not naturally inquire whether he is "free" or not to seek his own good, provided only he knows what it is, and that it is attainable by voluntary action. But when his conduct is compared with a code to the violation of which punishments are attached, the question whether he really could obey the rule by which he is judged is obvious and inevitable, since if he could not, it seems contrary to our sense of justice to punish him.

To sum up, the subject of Ethics, most comprehensively understood, includes (1) an investigation of the constituents and conditions of the Good or Well-being of men considered individually, which chiefly takes the form of an examination into the general nature and particular species of (*a*) Virtue or (*b*) Pleasure, and the chief means of realizing these ends; (2) an investigation of the principles and most important details of Duty or the Moral Law (so far as this is distinguished from Virtue); (3) some inquiry into the nature and origin of the Faculty by which duty is recognized; (4) some examination of the question of human Free Will. It is connected with Ontology or Theology, in so far as a Universal Good is recognized, inclusive of Human Good, or analogous to it; with Theology again, so far as morality is regarded as a Code of Divine appointment. It is connected with Politics, so far as the well-being of any individual man is bound up with the well-being of his society; and again with Jurisprudence (or Politics), so far as morality is identified with Natural Law. Finally, almost every branch of Ethical discussion belongs at least in part to Psychology; and the inquiries into the origin of the moral faculty and the freedom of the Will are purely psychological.

We will now proceed to trace briefly the course of ethical speculation from its origin in Europe to the present day; confining our attention, during the latter part of this period to such modes of thought as have been developed in England, or have exercised an important influence there.

II. GREEK AND GRÆCO ROMAN ETHICS.—The ethical speculation of Greece, and therefore of Europe, has not, any more than other elements of European civilization, an abrupt and absolute commencement. The naïve and fragmentary utterances of sage precepts for conduct, in which nascent moral reflection everywhere first manifests itself, supply a noteworthy element of Greek literature in the "gnomic" poetry of the 7th and 6th centuries before Christ; their importance in the development of Greek civilization is strikingly characterized by the traditional enumeration of the "seven sages" of the 6th century; and their influence on ethical thought is sufficiently shown in the references that Plato and even Aristotle make to the definitions and maxims of poets and sages. But from such utterances as these to moral philosophy there was still a long step; for though Thales (*circ.* 640–560 B.C.), one of the seven, was also the first physical philosopher of Greece, we have no ground for supposing that his practical wisdom had anything of a philosophical character. There seems to have been more connection between moral teaching and metaphysical speculation in the case of Pythagoras (*circ.* 580–500 B.C.), who is conspicuous among pre-Socratic philosophers as the founder not merely of a school, but rather of a sect or order, bound by a common rule of life. Certainly the doctrine of the Pythagoreans, that the essence of justice (conceived as equal retribution) was a square number, indicates a serious attempt to extend to the region of conduct that mathematical view of the universe which was the fundamental characteristic of Pythagoreanism; and the same may be said of their classification of good with unity, limit, straightness, light, etc., and of evil with the opposite qualities. Still, on the whole, the moral precepts of Pythagoras appear to have been announced much more in a dogmatic, or even prophetic, than in a philosophic manner; and, whether sound or arbitrary, to have been accepted by his disciples with a decidedly unphilosophic reverence for the "ipse dixit"[1] of the master. Hence, whatever influence the Pythagorean blending of ethical and mathematical notions may have had on Plato, and, through him, on later thought, we cannot regard the school as having really forestalled the Socratic inquiry after a completely reasoned theory of conduct. The ethical element in the "dark" philosophizing of Heraclitus (*circ.* 530–470 B.C.) shows more profundity of view, but still less approximation to a system: in spite of the partial anticipation of Stoicism which we find in his conceptions of a law of the universe, to which the wise man will carefully conform, and a divine harmony, in the recognition of which he will find his truest satisfaction. It is only when we come to Democritus, a contemporary of Socrates, the last of the series of original thinkers whom we distinguish as pre-Socratic, that we find anything which we can call an ethical system. The fragments that remain of the moral treatises of Democritus are sufficient, perhaps, to convince us that the turn of Greek philosophy in the direction of conduct, which was actually due to Socrates, would have taken place without him, though in a less decided manner; but when we compare the Democritean ethics with the post-Socratic system to which it has most affinity, Epicureanism, we find that it exhibits a very rudimentary apprehension of the formal conditions which moral teaching must fulfil before it can lay claim to be treated as scientific.

---

[1] This well-known phrase was originally attributed to the Pythagoreans.

The fact is that a moral system could not satisfactorily be constructed until attention had been strongly directed to the vagueness and inconsistency of the common moral opinions of mankind; until this was done, the moral counsels of the philosopher, however supreme his contempt for the common herd, inevitably shared these defects. For this purpose was needed the concentration of a philosophic intellect of the first order on the problems of practice. In Socrates, for the first time, we find the required combination of a genuine ardor for knowledge, and a paramount interest in conduct. The pre-Socratic thinkers, from Thales downwards, were all primarily devoted to ontological research; but by the middle of the 5th century B.C. the clash and conflict of their dogmatic systems had led some of the keenest minds to doubt the possibility of penetrating the secret of the universe. This doubt found expression in the reasoned scepticism of Gorgias, and produced the famous doctrine of Protagoras, that the human apprehension is the only standard of what is and what is not. A similar view of the natural limits of the human intellect repelled the philosophic ardor of Socrates from physico-metaphysical inquiries. In his case, moreover, such a view found support in a naïve piety that indisposed him to search into things of which the gods seemed to have reserved the knowledge to themselves. The regulation of human action, on the other hand (except on occasions of special difficulty, for which omens and oracles might be vouchsafed), they had left to human reason; on this accordingly Socrates concentrated his efforts.

The age of the Sophists.

The demand for an art of conduct was not, however, original in Socrates, though his conception of the requisite knowledge was so in the highest degree. The thought of the most independent thinker is conditioned by that of his age; and we cannot disconnect the work of Socrates from the professional instruction in conduct which is so striking a phenomenon of this period of Greek civilization. The origination of this kind of teaching seems to have been due to the genius of Protagoras; whom we may suppose to have been turned, like Socrates, to the study of human affairs in consequence of his negative attitude towards current ontological speculation. This instruction, conveyed in well-thronged lectures, does not seem to have been based on any philosophical system, and was in fact of too popular a quality to be of much philosophical importance. It seems to have combined somewhat loosely the art of getting on in the world with the art of managing public affairs, and to have mingled encomiastic expositions of different virtues with prudential justifications of virtue, as a means of obtaining pleasure and avoiding pain. But however commonplace the teaching of the "sophists" may have been, the general fact of the appearance of this new profession to meet a new social need is sufficiently remarkable. How came it that after so many centuries, in which Greeks had used their moral notions with the confidence of perfect knowledge, and attributed to any cause rather than ignorance the extensive failure of men to realize virtue, they should suddenly become persuaded that good conduct was something that could be learnt from lectures? It must be borne in mind that in the Greek conception of virtue the moral view of life was not separated from the prudential; the ἀρετή which the sophists professed to communicate was not strictly virtue, as distinguished from other skills and gifts that sustain and enrich life. Thus while in this age, as in more modern times, most men would suppose that they had sufficient knowledge of justice and temperance, they would not be equally confident that they possessed the art of making the best of life generally. We must remember, too, the importance of the civic or public side of life to a free-born leisured Greek in the small town communities of this age. The art of conduct as professed and taught to him would mean to a great extent the art of public life; indeed, Plato's *Protagoras* defines his function to be that of teaching "civic excellence" in distinction from other skills (as that of flute-playing), which might also be included under the notion of ἀρετή. It is more natural that a plain man should think scientific training necessary in dealing with affairs of state than in his own private concerns.

Still this emergence of an art of conduct with professional teachers cannot thoroughly be understood, unless it is viewed as a crowning result of a general tendency at this stage of Greek civilization to substitute technical skill for traditional procedure and empirically developed faculty. In the age of the sophists we find, wherever we turn, the same eager pursuit of knowledge, and the same eager effort to apply it directly to practice. The method of earth-measurement was rapidly becoming a science; the astronomy of Meton was introducing precision into the computation of time; Hippodamus was revolutionizing architecture by building towns with straight broad streets; old-fashioned soldiers were grumbling at the new pedantries of "tactics" and "hoplitics;" the art of music had recently received a great technical development; and a still greater change had been effected in that training of the body which constituted the other half of ordinary Greek education. If bodily vigor was no longer to be left to nature and spontaneous exercise, but was to be attained by the systematic observance of rules laid down by professional trainers, it was natural to think that the same might be the case with mental excellences. The art of rhetoric, again, which was developed in Sicily in the second half of the 5th century, is a specially striking example of the general tendency we are here considering; and it is important to observe that the profession of rhetorician was commonly blended with that of sophist. Indeed throughout the age of Socrates sophists and philosophers were commonly regarded, by those who refused to recognize their higher claims, as teaching an "art of words." It is easy to see how this came about; when the demand of an art of conduct made itself felt, it was natural that the rhetoricians, skilled as they were in handling the accepted notions and principles of practice, should come forward to furnish the supply. Nor is there any reason to regard them as conscious charlatans for so doing, any more than the professional journalist of our own day, whose position as a political instructor of mankind is commonly earned rather by a knack of merely writing than by any special depth of political wisdom. As Plato's *Protagoras* says, the sophist in professing to teach virtue only claimed to do somewhat better than others what all men are continually doing; and similarly we may say that, when tried by the touchstone of Socrates, they only exhibited somewhat more conspicuously than others the deficiencies which the great questioner found everywhere.

Socrates.

The charge that Socrates brought against the sophists and his fellow-men generally may be viewed in two aspects. On one side it looks quite artless and simple; on the other it is seen to herald a revolution in scientific method, and to contain the germ of a metaphysical system. Simply stated, the charge was that they talked about justice, temperance, law, etc., and yet could not tell what these things were; the accounts of them which they gave when pressed were, as Socrates forced them to admit, inconsistent with their own judgments on particular instances of justice, legality, etc. This "ignorance" of the real meaning of their terms was not, indeed, the only lack of knowledge that Socrates discovered in his contemporaries, but it was the chief, and it was in the exposure of this that the philosophic importance of his work lay. For the famous "dialectic," by which he brought this ignorance home to his interlocutors, at once exhibited the scientific need of exact definitions of general notions, and suggested that these definitions were to be attained by a careful comparison of particulars. Thus, we can understand how, in Aristotle's view, the main service of Socrates to philosophy consisted in "introducing induction and definitions." This description, however, is both too technical and too positive to represent the naïve and negative character of the Socratic dialectic. For that the results of these resistless arguments were mainly negative is plain from those (earlier) Platonic dialogues in which the impression of the real Socrates is to be found least modified. The pre-eminent "wisdom" which the Delphic oracle attributed to him was held by himself to consist in a unique consciousness of ignorance. And yet it is equally plain, even from Plato, that there was a most important positive element in the teaching of Socrates; had it been otherwise, the attempt of Xenophon to represent his discourses as directly edifying, and the veneration felt for him by the most dogmatic among subsequent schools of philosophy, would be quite inexplicable.

The union of these two elements in the work of Socrates has caused historians no little perplexity; and certainly we cannot quite save the philosopher's consistency, unless we regard some of the doctrines attributed to him by Xenophon as merely tentative and provisional. Still the positions of Socrates that are most important in the history of ethical thought are not only easy to harmonize with his conviction of ignorance, but even render it easier to understand his unwearied cross-examination of common opinion. For the radical and most impressive article of his creed was constituted by his exalted estimate of this knowledge that was so hard to find, his conviction that ignorance of the good and evil in human life was the source of all practical error. If his habitual inquiries were met by the reply, "We do know what justice and holiness are, though we cannot say," he would rejoin, "Whence, then, these perpetual disputes about what is just and holy?" True knowledge, he urged, would settle these quarrels, and produce uniformity in men's moral judgments and conduct. To us, no doubt, it seems an extravagant paradox to treat men's ignorance of justice as the sole cause of unjust acts; and to the Greek mind also the view was paradoxical; but if we would understand the position, not of Socrates only, but of ancient ethical philosophy generally, we must try to realize that this paradox was also a nearly unanswerable deduction from a pair of truisms. That "every one wishes for his own good, and would get it if he could," an arguer would hardly venture to question; and he would equally shrink from denying that justice and virtue generally were goods, and of all goods the finest. How then could he refuse to admit that "those who knew how to do just and righteous acts would prefer nothing else, while those who did not know could not do them if they would,"[1] which would land him at once in the conclusion of Socrates that "all virtues were summed up in wisdom or knowledge of Good." Observe that we are not to understand this "knowledge of good" as if it were knowledge of duty as distinct from interest. The force of the above argument depends upon a blending of duty and interest in the single notion of good. This blending Socrates did not, of course, invent —he found it in the common thought of his age; but it was the primary moral function of his dialectic to educe and exhibit it, to drive it home and trace its practical consequences. A resolute assertion of the coincidence of different elements of good, as commonly recognized, forms the kernel of the positive moral teaching that Xenophon attributes to him. He could give no account that satisfied him of good in the abstract; when pressed for one he evaded the questioners by saying that "he knew no good that was not good for something in particular;" but that good is consistent with itself, that the beautiful is also profitable, the virtuous also pleasant, he was always ready to prove in concrete cases. If he prized the wisdom that is virtue, the "good of the soul," above all other goods, if in his unreserved devotion to the task of producing it in himself and others he endured the hardest penury, he steadily maintained that such life was richer in enjoyment than a life of luxury; if he faced death rather than violate the laws of his country, he was prepared with a complete proof that it was probably his interest to die.

This many-sidedness in his view of good is strikingly illustrated by the curious blending of elevated and vulgar sentiment which his utterances about friendship show. If goodness of soul is the "finest of goods," a good friend must be the most valuable of external possessions; no effort is too great to keep or win such. Still, the good of friendship must be shown in its utility; a friend who can be of no service is valueless; and this "service" Socrates on occasion interpreted in the most homely and practical sense. Still, the highest of services that friend can render to friend is moral improvement.

To sum up, then, we may describe the relation of Socrates to the common sense of his age as that of perpetual particular scepticism, combined with permanent general faith. He is always attacking common opinion, and showing it, from its inconsistencies, not to be knowledge; but the premises of his arguments are always taken from common opinion, and the knowledge which he seeks is something that will harmonize, not overthrow it. This knowledge is not merely knowledge of Good, though that is the chief and crown of it; he is continually inquiring for definitions of all the notions that enter into practical reasonings, whether for the regulation of public or private conduct, and is unwearied in studying the *rationale* of even the most subordinate acts of life. In fact, he required of all men, whatever their special business might be, that they should know what they were doing and why,—should act on some clear and consistent theory; the requirement was startling to many, but to all philosophic souls it was not the less irresistible because it was usually indirect. The necessity, indeed, for firmness of purpose[2] as well as clearness of insight he did not expressly recognize, but this quality was all the more conspicuously manifested in his life. Indeed, it was the very perfection in which he possessed this virtue that led him to the paradox of ignoring it. Of himself at least it was true, that whatever he believed to be "fair and good" he must necessarily do; when another acted apparently against knowledge, the easiest explanation seemed to him to be that true knowledge was not really there.

These, then, seem the historically important characteristics of the great founder of moral philosophy, if we take (as we must) his teaching and character together:—(1) an ardent inquiry for knowledge nowhere to be found, but which, if found, would perfect human conduct; (2) a demand meanwhile that men should act as far as possible on some consistent theory; (3) a provisional adhesion to the commonly received view of good, in all its incoherent complexity, and a perpetual readiness to maintain the unity of its different elements, and demonstrate the superiority of virtue by applying the commonest standard of self-interest; (4) personal firmness, as apparently easy as it was actually invincible, in carrying out such practical convictions as he had attained. It is only when we keep all these points in view that we can understand how from the spring of Socratic conversation flowed the branching rivers of Greek ethical thought.

The Socratic schools.

Four distinct philosophical schools trace their immediate origin to the circle that gathered round Socrates—the Megarian, the Platonic, the Cynic, and the Cyrenaic. The impress of the master is manifest on all, in spite of the wide differences that divided them; and they all agree in holding the most important possession of man to be wisdom or knowledge, and the most important knowledge to be knowledge of Good. Here, however, the agreement ends. The more philosophic part of the circle, forming a group in which Euclides of Megara seems at first to have taken the lead, regarded this Good as the object of a still unfulfilled quest; and setting out afresh in search of it, with a profound sense of its mystery, were led to identify it with the hidden secret of the universe, and thus to pass from ethics to metaphysics. Others again, whose demand for knowledge was more easily satisfied, and who were more impressed with the positive and practical side of the master's teaching, made the quest a much simpler affair; in fact, they took the Good as already known, and held philosophy to consist in the steady application of this knowledge to conduct. Among these were Antisthenes the Cynic and Aristippus of Cyrene. It is by their unreserved recognition of the duty of living consistently by theory, their sense of the new value given to life through this rationalization, and their effort to maintain the easy, calm, unwavering firmness of the Socratic temper, that we recognize both Antisthenes and Aristippus as "Socratic men," in spite of the completeness with which they divided their master's positive doctrine into systems diametrically opposed. Of their contrasted principles we may perhaps say that, while Aristippus took the most obvious logical step for reducing the teaching of Socrates to clear dogmatic unity, Antisthenes certainly drew the most natural inference from the Socratic life.

---

[1] *Cf.* Xenophon, *Memorabilia*, ix. 4, where Xenophon fully confirms what Plato's dialogues abundantly illustrate.

[2] Xenophon, it is true, describes him as exalting "self-control," ἐγκράτεια; and Mr. Grote (*Hist. of Greece*, vol. viii. c. 68) finds this inconsistent with his fundamental principle. But there appears no reason for supposing that Socrates (or Xenophon) formally distinguished ἐγκράτεια from σωφροσύνη as Aristotle does; and it is quite easy to interpret the ordinary notion of "self-control" Socratically, as essentially consisting in knowledge of the comparatively small value of gratification of vicious appetite.

Aristippus.

Aristippus argued that, if all that is beautiful or admirable in conduct has this quality as being useful, *i.e.*, productive of some further good; if virtuous action is essentially action done with insight, or rational apprehension of the act as a means to this good; then surely this good can be but pleasure, which all living things with unperverted impulses seek, while they shun its opposite, pain. He further found a metaphysical basis for this conclusion in the doctrine to which the relativism of Protagoras led him, that we can know nothing of things without us except their impressions on ourselves. An immediate inference from this is the "smooth motion" of sense which we call pleasure, from whatever source it came, as the only cognizable good; no kind of pleasure being in itself better than any other, though some kinds were to be rejected for their painful consequences. Bodily pleasures and pains Aristippus held to be the keenest; though he does not seem to have maintained this on any materialistic theory, as he admitted the existence of purely mental pleasures, such as joy in the prosperity of our fatherland. He fully recognized that his good was transient, and only capable of being realized in successive parts; giving even exaggerated emphasis to the rule of seeking the pleasure of the moment, and not troubling one's self about a dubious future. It was in the calm, resolute, skilful culling of such pleasures as circumstances afforded from moment to moment, undisturbed by passion, prejudices, or superstition, that he conceived the quality of wisdom to be exhibited; and tradition represents him as realizing this ideal to an impressive degree. Among the prejudices from which the wise man was free he included all regard to customary morality beyond what was due to the actual penalties attached to its violation; though he held, with Socrates, that these penalties actually render conformity reasonable.

The Cynics.

Far otherwise was the Socratic spirit understood by Antisthenes and the Cynics. They equally held that no speculative research was needed for the discovery and definition of Good and Virtue; but they maintained that the Socratic wisdom, on the exercise of which man's well-being depended, was exhibited, not in the skilful pursuit, but in the rational disregard of pleasure,—in the clear apprehension of the intrinsic worthlessness of this and most other objects of men's common aims. Antisthenes, indeed, did not overlook the need of supplementing merely intellectual insight by "Socratic force of soul;" but it seemed to him that, by insight and invincible self-mastery combined, an absolute spiritual independence might be attained which left nothing wanting for perfect well-being. What, indeed, could be wanting to the free rational soul, when imaginary needs, illusory desires, and idle prejudices were all discarded. For as for poverty, painful toil, disrepute, and such evils as men dread most, these, he argued, were positively useful as means of progress in spiritual freedom and virtue. The eccentricities with which his disciple Diogenes flaunted and revelled in this freedom have made him one of the most familiar figures of ancient social history, and one which in its very extravagance gives a vivid impression of that element in the Socratic pattern which it involuntarily caricatures. Vainly, however, do we seek a definite positive import for the Cynic notion of wisdom or moral insight, besides the mere negation of irrational desires and prejudices. We saw that Socrates, while not claiming to have found the abstract theory of Good or Wise conduct, practically understood it to consist in the faithful performance of customary duties, maintaining always that his own happiness was therewith bound up. The Cynics more boldly discarded both pleasure and mere custom as alike irrational; but in so doing they left the freed reason with no definite aim but its own freedom. It is absurd, as Plato urged, to say that knowledge is the good, and then when asked "knowledge of what?" to have nothing positive to reply but "of the good;" but the Cynics do not seem to have made any serious effort to escape from this absurdity.

The ultimate views of these two one-sided Socraticisms we shall have to notice presently when we come to the post-Aristotelian schools. We must now proceed to the more complicated task of tracing the fuller development of the Socratic germ to its Platonic blossom and Aristotelian fruit.

Plato.

We can see that the influence of more than one of the earlier metaphysical schools combined with that of Socrates to produce the famous idealism which subsequent generations have learnt from Plato's dialogues; but the precise extent and manner in which each element co-operated is difficult even to conjecture.[1] Here, however, we may consider Plato's views merely in their relation to the teaching of Socrates, since to the latter is certainly due the ethical aspect of idealism with which we are at present concerned.

The ethics of Plato cannot properly be treated as a finished result, but rather as a continual movement from the position of Socrates towards the more complete and articulate system of Aristotle; except that there is a mystical element at the core of Plato's teaching which finds no counterpart in Aristotle, and in fact disappears from Greek philosophy soon after Plato's death until it finds a partial revival and fantastic development in Neo-Pythagoreanism and Neo-Platonism. The first stage at which we can distinguish Plato's ethical view from that of Socrates is presented in the *Protagoras*, where he makes a serious, though clearly tentative, effort to define the object of that knowledge which he regards, with his master, as the essence of all virtue. This science, he here maintains, is really mensuration of pleasures and pains, by which the wise man avoids those mistaken under-estimates of the value of future feelings in comparison with present which we commonly call "yielding to fear or desire." This thorough-going hedonism has somewhat perplexed Plato's readers; but (as was said in speaking of the similar view of the Cyrenaics), when a disciple sought to make clear and definite the essentially Socratic doctrine that the different common notions of good,—the beautiful, the pleasant, and the useful,—were to be somehow identified and interpreted by each other, hedonism presented itself as the most obvious conclusion. By Plato, however, this conclusion could only have been held before he had accomplished the movement of thought by which he carried the Socratic method beyond the range of human conduct, and developed it into a metaphysical system.

This movement may be briefly expressed thus. "If we know," said Socrates, "what justice is, we can give an account or definition of it;" true knowledge—to put it more technically—must be knowledge of the general fact, common to all the individual cases to which we apply our general notion. But why should we restrict this notion within the range of human conduct? The same relation of general notions to particular examples extends through the whole physical universe; we can only think and talk of it by means of such notions. It must be equally true everywhere that true or scientific knowledge is general knowledge, relating, not to individuals primarily, but to the general facts or qualities which individuals exemplify; in fact, our notion of an individual, when examined, is found to be an aggregate of such general qualities. But, again, the object of true knowledge must be what really exists; hence the most real reality, the essence of the universe, must lie in these general facts, and not in the individuals that exemplify them.

So far the steps are plain enough; but we do not yet see how this logical Realism (as it was afterwards called) comes to have the essentially ethical character that especially interests us in Platonism. For though Plato's philosophy is now concerned with the whole universe of being, the ultimate object of his philosophic contemplation is still "the good," now conceived as the ultimate ground of all being and knowledge. That is, the essence of the universe is identified with its end,—the "formal" with the "final" cause of things, to use the later Aristotelian phraseology. How comes this about?

Perhaps we may best explain this by recurring to the original application of the Socratic method to human affairs. Since all rational activity is for some end, the different arts or functions into which human industry is divided are naturally defined by a statement of their ends or uses; and similarly, in giving an account of the different artists and functionaries, we necessarily state their end, "what they are good for." It is only so far as they realize this end that they are what we call them. A painter who cannot paint is, as we say, "no painter;" or, to take a favorite Socratic illustration, a ruler is essentially one who realizes the well-being of the ruled; if he fails to do this, he is not, properly speaking, a ruler at all. And in a society well ordered on Socratic principles, every human being would be put to some use; the essence of his life would consist in doing what he was good for. But again, it is easy to extend this view throughout the whole region of organized life; an eye that does not attain its end by seeing is without the essence of an eye. In short, we may say of all organs and instruments that they are what we think them in proportion as they fulfil their function and attain their end: If, then, we conceive the whole universe organically, as a complex arrangement of means to ends, we shall understand how Plato might hold that all things really *were*, or (as we say) "realized their idea," in proportion as they accomplished the special end or good for which they were adapted. Even Socrates, in spite of his aversion to physics, was led by pious reflection to expound a teleological view of the physical world, as subservient in all its parts to divine ends; and in the metaphysical turn which Plato gave to this view, he was probably anticipated by Euclides of Megara, who held that the one real being is "that which we call by many names, Good, Wisdom, Reason, or God;" to which Plato, raising to a loftier significance the Socratic identification of the beautiful with the useful, added the further name of absolute Beauty.

---

[1] The difficulty arises thus:—(1) Aristotle represents Platonism as having sprung from Socratic teaching combined with Heraclitus's doctrine of the flux of sensible things, and the Pythagorean theory that numbers were the real; but (2) in the Megarian doctrine the non-Socratic element is clearly the one changeless being of Parmenides; while (3) the original connection of Plato and Euclides is equally evident.

Let us conceive, then, that Plato has taken this vast stride of thought, and identified the ultimate notions of ethics and ontology. We have now to see what attitude this will lead him to adopt towards the practical inquiries from which he started. What will now be his view of wisdom, virtue, pleasure, and their relation to human well-being?

The answer to this question is inevitably somewhat complicated. In the first place we have to observe that philosophy has now passed definitely from the market-place into the study or lecture-room. The quest of Socrates was for the true art of conduct for an ordinary member of the human society, a man living a practical life among his fellows. But if the objects of abstract thought constitute the real world, of which this world of individual things is but a shadow, it is plain that the highest, most real life must lie in the former region and not in the latter. We thus reach the paradox that Plato enforced in more than one of his most impressive dialogues, that the true art of living is really an "art of dying" as far as possible to mere sense, in order more fully to exist in intimate union with absolute goodness and beauty. On the other hand, in so far as this philosophic abstraction from ordinary human interests can never be complete, since the philosopher must still live and act in the concrete sensible world, the Socratic identification of wisdom and virtue is fully maintained by Plato. Only he who apprehends good in the abstract can imitate it in such transient and imperfect good as admits of being realized in human life, and it is impossible, having this knowledge, that he should not act on it, whether in private or public affairs. Thus, in the true philosopher, we shall necessarily find the practically good man, he who being "likest of men to the gods is best loved by them;" and also the perfect statesman, if only the conditions of his society allow him a sphere for exercising his statesmanship.

When we come to examine the characteristics of this practical goodness, we find that they correspond to the fundamental conceptions in Plato's view of the universe. We have seen that he conceives the world of being as—(1) essentially ideal and knowable; (2) organized and fitted for realization of good. Accordingly the soul of man, in its good or normal condition, must be (1) wise or knowing, (2) ordered, regulated, and harmonized. The question then arises, "Wherein does this order or harmony precisely consist?" In explaining how Plato was led to answer this question, it will be well to notice that, while faithfully maintaining the Socratic doctrine that the highest virtue was inseparable from knowledge of the good, he had come, as his conception of this knowledge deepened and expanded, to recognize an inferior kind of virtue, possessed by men who were not philosophers. It is plain that if the good that is to be known is the ultimate ground of the whole of things, so that the knowledge of it includes all other knowledge, it is only attainable by a select and carefully trained few, and we can hardly restrict all virtue to these alone. What account, then, was to be given of ordinary "civic" bravery, temperance, and justice? It seemed clear that men who did their duty, resisting the seductions of fear and desire, must have right opinions, if not knowledge, as to the good and evil in human life; but whence comes this right "opinion"? Partly, Plato, said, it comes by nature and "divine allotment," but for its adequate development "custom and practice" are required. Hence the paramount importance of education and discipline for civic virtue; and even for future philosophers such moral culture, in which physical and æsthetic training must co-operate, is an indispensable pre-requisite; no merely intellectual preparation will suffice. What, then, is the precise effect of this culture if it does not merely develop the intellect? A distinct step in psychological analysis was taken when Plato recognized that its effect was to produce the "harmony" above mentioned among different parts of the soul, by subordinating the impulsive elements to reason. These impulsive elements he further distinguished as appetitive and combative, founding on this triple division of the soul a systematic view of the four kinds of goodness chiefly recognized by the common moral consciousness of Greece, and in later times known as the cardinal[1] virtues. Of these two most fundamental were (as has been already indicated) wisdom—in its highest form philosophy—and that harmonious regulation of psychical impulses and activities which Plato gives as the essence of *δικαιοσύνη*. This term in ordinary use had a wider meaning than our "justice," and might without much straining denote uprightness in social relations generally. Still, its import is essentially social; and we can only explain Plato's use of it by reference to the analogy which his analysis of the soul led him to draw between the individual man and the community. For in this latter also he regarded the regulative and combative elements as naturally distinct from the common herd, who are concerned with merely material interests; so that social and individual well-being would depend on the same harmonious action of diverse elements, which in its social application is more naturally termed *δικαιοσύνη*. We see that these two fundamental virtues are mutually involved. Wisdom will necessarily maintain orderly activity, and this latter consists in regulation by wisdom, while the two more special virtues of courage and temperance (*σωφροσύνη*) are only different sides or aspects of this wisely regulated action of the complex soul. We may observe that this fourfold division of virtue was generally accepted in ethical discussion after Plato; though the notions were somewhat differently defined by different thinkers, and the peculiar Platonic interpretation of justice for the most part abandoned.

Such, then, are the forms in which essential good seemed to manifest itself in human life; it remains to ask whether the statement of these gives a complete account of human well-being, or whether pleasure is also to be included. On this point Plato's view seems to have gone through several oscillations. After apparently maintaining (*Protagoras*) that pleasure is *the* good, he passes first to the opposite extreme, and denies it (*Phædo*, *Gorgias*) to be a good at all. Not only is it, as concrete and transient, obviously not the real essential good that the philosopher seeks; it is found further that the feelings most prominently recognized as pleasures are bound up with pain, as good can never be with evil; since they are the mere satisfaction of painful wants and cease with the removal of these; in so far, then, as common sense rightly recognizes some pleasures as good, it can only be from their tendency to produce some further good. This view, however, was too violent a divergence from Socratism for Plato to remain in it. That pleasure is not the real absolute good, was no ground for not including it in the good of concrete human life; and after all it was only coarse and vulgar pleasures that were indissolubly linked to the pains of want. Accordingly, in the *Republic* he has no objection to try the question of the intrinsic superiority of philosophic or virtuous[2] life by the standard of pleasure; arguing that the philosophic (or good) man alone enjoys real pleasure, while the sensualist spends his life in oscillating between painful want and the merely neutral state of painlessness, which he mistakes for positive pleasure. In the *Philebus*, however, though a more careful psychological analysis leads him to soften down the exaggerations of this attack on sensual pleasure the antithesis of knowledge and pleasure is again sharpened, and a desire to depreciate even good pleasures is more strongly shown; still even here pleasure is recognized as a constituent of that philosophic life which is the highest human good, while in the *Laws*, where the subject is more popularly treated, it is admitted that we cannot convince man that the just life is the best unless we can also prove it to be the pleasantest.

---

[1] The term "cardinalis" is Christian; it is first found in Ambrose (*In Luc.* § 62).

[2] It is highly characteristic of Platonism that the issue in this dialogue, as originally stated, is between virtue and vice, whereas, without any avowed change of ground, the issue ultimately discussed is between the philosophic life and the life of vulgar ambition or sensual enjoyment.

Plato and Aristotle.

When a student passes from Plato to Aristotle, he is so forcibly impressed by the contrast between the habits of mind of the two authors and their manners of literary expression, that it is easy to understand how their systems have come to be popularly conceived as diametrically opposed to each other; and the uncompromising polemic which Aristotle, both in his ethical and his metaphysical treatises, directs against Plato and the Platonists, has tended strongly to confirm this view. Yet a closer inspection shows us that when a later president of the Academy (Antiochus of Ascalon) repudiated the scepticism which for two hundred years had been accepted as the traditional Platonic doctrine, he had good grounds for claiming Plato and Aristotle as coincident authorities for the ethical position which he took up. The truth is that, though Aristotle's divergence from Plato is very conspicuous when we consider either his general conception of the subject of ethics, or the scientific working out of his system of virtue, still his agreement with his master is almost complete as regards the main outline of his theory of human good; the difference between the two practically vanishes when we view them in relation to the later controversy between Stoics and Epicureans. Even on the cardinal point on which Aristotle entered into direct controversy with Plato, the definite disagreement between the two is less than at first appears; the objections of the disciple hit that part of the master's system that was rather imagined than thought; the positive result of Platonic speculation only gains in distinctness by the application of Aristotelian analysis.

Plato, we saw, held that there is one supreme science or wisdom, of which the ultimate object is absolute good; in the knowledge of this, the knowledge of all particular goods,—that is, of all that we rationally desire to know,—is implicitly contained; and also all practical virtue, as no one who truly knows what is good can fail to realize it. But in spite of the intense conviction with which he thus identified metaphysical speculation and practical wisdom, we find in his writings no serious attempt to deduce the particulars of human well-being from his knowledge of absolute good, still less to unfold from it the particular cognitions of the special arts and sciences. Indeed, we may say that the distinction which Aristotle explicitly draws between speculative science or wisdom, which is concerned with the eternal and immutable truths of being, and practical wisdom (on its political side statesmanship), which has for its object "human" or "practicable" good, is really indicated in Plato's actual treatment of the subjects, although the express recognition of it is contrary to his principles. The discussion of good (*e.g.*) in his *Philebus* relates entirely to human good, and the respective claims of Thought and Pleasure to constitute this; he only refers in passing to the Divine Thought that is the good of the ordered world, as something clearly beyond the limits of the present discussion. So again, in his last great ethico-political treatise (the *Laws*) there is hardly a trace of his peculiar metaphysics: it is from the union of practical wisdom (*τὸ φρονεῖν*) —not philosophy—with power that the realization of the ideal state is now expected. On the other hand, the relation between human and divine good, as presented by Aristotle, is so close that we can hardly conceive Plato as having definitely thought it closer. The substantial good of the universe, in Aristotle's view, is the pure activity of universal abstract thought, at once subject and object, which, itself changeless and eternal, is the final cause and first source of the whole process of change in the concrete world. And he holds, with Plato, that a similar activity of pure speculative intellect is the highest and best mode of human existence, and that in which the philosopher will seek to exist as far as possible; though he must, being a man, concern himself with the affairs of ordinary human life, in which region his highest good will be attained by realizing perfect moral excellence. No doubt Aristotle's demonstration of the inappropriateness of attributing moral excellence to the Deity seems to contradict Plato's doctrine that the just man as such is "likest the gods;" but here again the discrepancy is reduced when we remember that the essence of Plato's justice (*δικαιοσύνη*) is harmonious activity. Nor, again, is Aristotle's divergence from the Socratic principle that all "virtue is knowledge" substantially greater than Plato's. Both accept the paradox in the qualified sense that no one can deliberately act contrary to what appears to him good, and that perfect virtue is inseparably bound up with perfect wisdom or moral insight. Both, however, see that this moral insight is not to be imparted by mere teaching, but depends rather on careful training in good habits applied to minds of good natural dispositions; though the doctrine has no doubt a more definite and prominent place in Aristotle's system. In the same way the latter draws more clearly, and develops more fully, the distinction between impulsive offences and the deliberate choice of evil for good which belongs to confirmed vice; which is, however, implied in Plato's later recognition (in the *Sophista*) of "disorder" of the soul as a kind of badness essentially different from ignorance. The disciple, no doubt, takes a step in advance by stating definitely, as an essential characteristic of virtuous action, that it is chosen for its own sake, for the beauty of virtue alone; but herein he merely formulates the conviction that his master more persuasively inspires. Nor, finally, does Aristotle's account of the relation of pleasure to human well-being differ materially from the outcome of Plato's thought on this point, as the later dialogues present it to us; although he has to combat the extreme anti-hedonism to which the Platonic school under Speusippus had been led. Pleasure, in Aristotle's view, is not the essence of well-being, but rather an inseparable accident of it; human well-being is essentially well-doing, excellent activity of some kind, whether its aim and end be abstract truth or noble conduct; but all activities are attended and in a manner perfected by pleasure, which is better and more desirable in proportion to the excellence of the activity. He no doubt criticises Plato's account of the nature of pleasure, arguing that we cannot properly conceive pleasure either as a "process" or as "replenishment"—the last term, he truly says, denotes a material rather than a psychical fact; but this does not interfere with the general ethical agreement between the two; and the doctrine that vicious pleasures are not true or real pleasures is so characteristically Platonic that we are almost surprised to find it in Aristotle.

Aristotle's ethics.

In so far as there is any important difference between the Platonic and the Aristotelian views of human good, we may observe that the latter is substantially the more faithful development of the ethical teaching of Socrates, although it is presented in a far more technical and scholastic form, and involves a more distinct rejection of the fundamental Socratic paradox. The same result appears when we compare the methods of the three philosophers. Although the Socratic induction forms a striking feature of Plato's dialogues, his ideal method of ethics is purely deductive; he only admits common sense as supplying provisional steps and starting points from which the mind is to ascend to knowledge of absolute good; by deduction from which, as he conceives, the lower notions of particular goods are to be truly apprehended. Aristotle, discarding the transcendentalism of Plato, naturally receded towards the original Socratic method of induction from and verification by common opinion. Indeed, the turns and windings of his exposition are best understood if we consider his literary manner as a kind of Socratic dialogue formalized and reduced to a monologue—transferred, we may say, from the market-place to the lecture-room. He first leads us by an induction to the fundamental notion of ultimate end or good for man. All men, in acting, aim at some result, either for its own sake or as a means to some further end; but obviously everything cannot be sought merely as a means; there must therefore be some ultimate end. In fact men commonly recognize such an end, and agree to call it well-being[1] (*εὐδαιμονία*); but they take very different views of its nature. How, then, shall we find the true view? Another genuinely Socratic induction leads us to this. We observe that men are classified and named according to their functions; all kinds of man, and indeed all organs of man, have their special functions, and are judged as functionaries and organs to be in good or bad condition according as they perform their functions well or ill. May we not then infer that man, as man, has his proper function, and that the well-being or "doing well" that all seek really lies in fulfilling well the proper function of man,—that is, in living well that life of the rational soul which we recognize as man's distinctive attribute?

---

[1] This cardinal term is commonly translated "happiness;" and it must be allowed that it is the most natural term for what we (in English) agree to call "our being's end and aim." But happiness so definitely signifies a state of feeling that it will not admit the interpretation that Aristotle (as well as Plato and the Stoics) expressly gives to *εὐδαιμονία*; hence the rendering *εὐδαιμονία* by happiness has caused serious confusion to the students of Greek philosophy

Again, this Socratic deference to common opinion is not merely shown in the way by which Aristotle reaches his fundamental conception; it equally appears in his treatment of the conception itself. In the first place, though in Aristotle's view the most perfect well-being consists in the exercise of man's "divinest part," pure speculative reason, he keeps far from the paradox of putting forward this and nothing else as human good; so far, indeed, that the greater part of his treatise is occupied with an exposition of the inferior good which is realized in practical life when the appetitive or impulsive (semi-rational) element of the soul operates under the due regulation of reason. Even when the notion of "good performance of function" was thus widened, and when it had further taken in the pleasure that is inseparably connected with such functioning, it did not yet correspond to the whole of what a Greek commonly understood as "human well-being;" though, in order to make it fit better, Aristotle emphasizes more than we should have expected the necessity of worldly goods for the realization of such virtues as liberality, justice, etc. There still remain other goods, such as beauty, good birth, welfare of posterity, etc., the presence or absence of which influenced the common view of a man's well-being, though they could not be shown to be even indirectly important to his "well-acting." These Aristotle neither attempts to exclude from the philosophic conception of well-being nor to include in his formal definition of it. The deliberate looseness which is thus given to his fundamental doctrine characterizes more or less his whole discussion of ethics. He plainly says that the subject does not admit of completely scientific treatment; his aim is to give not a perfectly definite theory of human good, but a practically adequate account of its most important constituents.

The most important characteristics, then, of well-being or good life for ordinary men are represented by the notions of the different moral excellences. In expounding these, Aristotle gives throughout the pure result of analytical observation of the common moral consciousness of his age. Ethical truth, in his view, is to be attained by induction from particular moral opinions, just as physical truth is to be obtained by induction from particular physical observations. On account of the conflict of opinion in ethics we cannot hope to obtain perfect clearness and certainty upon all questions; still reflection will lead us to discard some of the conflicting views and find a reconcilation for others, and will furnish, on the whole, a practically sufficient residuum of moral truth. In many respects this adhesion to common sense involves a sacrifice of both depth and completeness in Aristotle's system. His virtues are not arranged on any clear philosophic plan; the list shows no serious attempt to consider human life exhaustively, and exhibit the standard of excellence appropriate to its different departments or aspects. He seems to have taken as a starting-point Plato's four cardinal virtues. The two comprehensive notions of Wisdom and Justice (*δικαιοσύνη*) he treats separately. As regards both his analysis leads him to diverge considerably from Plato. As we saw, his distinction between practical and speculative Wisdom belongs to the deepest of his disagreements with his master; and in the case of *δικαιοσύνη* again he distinguishes the wider use of the term to express Law-observance, which (he says) coincides with the social side of virtue generally, and its narrower use for the virtue that "aims at a kind of equality," whether (1) in the distribution of wealth, honor, etc., or (2) in commercial exchange, or (3) in the reparation of wrong done. Then, in arranging the other special virtues, he begins with courage and temperance, which (after Plato) he considers as the excellences of the "irrational element" of the soul. Next follow two pairs of excellences, concerned respectively with wealth and honor:—(1) liberality and magnificence, of which the latter is exhibited in greater matters of expenditure, and (2) laudable ambition and high-mindedness similarly related to honor. Then comes gentleness—the virtue regulative of anger; and the list is concluded by the excellences of social intercourse, friendliness (as a mean between obsequiousness and surliness), truthfulness, and decorous wit.

The abundant store of just and close analytical observation contained in Aristotle's account of these notions give it a permanent interest, even beyond its historical value as a delineation of the Greek ideal of "fair and good" life.[1] But its looseness of arrangement and almost grotesque coordination of qualities widely differing in importance are obvious; and Aristotle's restriction of the sphere of courage to dangers in war, and of that of temperance to certain bodily pleasures, as well as his non-distinction of selfish and benevolent expenditure in describing liberality, illustrate the fragmentariness and superficiality of treatment to which mere analysis of the common usage of ethical terms is always liable to lead. Nor is his famous general formula for virtue, that it is a mean or middle state, always to be found somewhere between the vices which stand to it in the relation of excess and defect, of much avail in rendering his treatment more systematic. It was important, no doubt, to express the need of limitation and regulation, of observing due measure and proportion, in order to attain good results in human life no less than in artistic products; but the observation of this need was no new thing in Greek literature; indeed, it had already led the Pythagoreans and Plato to find the ultimate essence of the ordered universe in number. But Aristotle's purely quantitative statement of the relation of virtue and vice is misleading, even where it is not obviously inappropriate; and sometimes leads him to such eccentricities as that of making simple veracity a mean between boastfulness and mock-modesty.

It ought to be said that Aristotle does not present the formula just discussed as supplying a criterion of good conduct in any particular case; he expressly leaves this to be determined by "correct reasoning and the judgment of the practically wise man." We cannot, however, find that he has furnished any substantial principles for its determination; indead, he hardly seems to have formed a distinct general idea of the practical syllogism by which he conceives it to be effected.[2] And, indeed, it would not have been easy for him to make this point plain, without bringing into prominence a profound discrepancy between his own view of rational action and the common opinion and practice of mankind. The kind of reasoning which his view of virtuous conduct requires is one in which the ultimate major premise states a distinctive characteristic of some virtue, and one or more minor premises show that such characteristic belongs to a certain mode of conduct under given circumstances; since it is essential to good conduct that it should contain its end in itself, and be chosen for its own sake. But he has not failed to observe that practical reasonings are not commonly of this kind, but are rather concerned with actions as means to ulterior ends; indeed, he lays stress on this as a characteristic of the "political" life, when he wishes to prove its inferiority to the life of pure speculation. Though common sense will admit that virtues are the best of goods, it still undoubtedly conceives practical wisdom as chiefly exercised in providing those inferior goods which Aristotle, after recognizing the need or use of them for the realization of human well-being, has dropped out of sight; and the result is that, in trying to make clear his conception of practical wisdom, we find ourselves fluctuating continually between the common notion, which he does not distinctly reject, and the notion required as the keystone of his ethical system.

---

[1] Aristotle follows Plato and Socrates in identifying the notions of *καλός* ("fair," "beautiful") and *ἀγαθός* ("good") in their application to conduct. We may observe, however, that while the latter term is used to denote the virtuous man, and (in the neuter) equivalent to end generally, the former is rather chosen to express the quality of virtuous acts which in any particular case is the end of the virtuous agent. Aristotle no doubt faithfully represents the common sense of Greece in considering that, in so far as virtue is in itself good to the virtuous agent, it belongs to that species of good which we distinguish as beautiful. In later Greek philosophy the term *καλόν* ("honestum") became still more technical in the signification of "morally good."

[2] There is a certain difficulty in discussing Aristotle's views on the subject of practical wisdom, and the relation of the intellect to moral action, since it is most probable that the only accounts that we have of these views are not part of the genuine writings of Aristotle. Still books vi. and vii. of the *Nicomachean Ethics* contain no doubt as pure Aristotelian doctrine as a disciple could give, and appear to supply a sufficient foundation for the general criticism expressed in the text.

Transition to Stoicism.

On the whole, there is probably no treatise so masterly as Aristotle's *Ethics*, and containing so much close and valid thought, that yet leaves on the reader's mind so strong an impression of dispersive and incomplete work. It is only by dwelling on these defects that we can understand the small amount of influence that his system exercised during the five centuries after his death, in which the schools sprung from Socrates were still predominant in Græco-Roman culture; as compared with the effect which it has had, directly or indirectly, in shaping the thought of modern Europe. Partly, no doubt, the limited influence of the "Peripatetics"[1] (as Aristotle's disciples were called) is to be attributed to that exaltation of the purely speculative life which distinguished the Aristotelian ethics from other later systems, and which was too alien from the common moral consciousness to find much acceptance in an age in which the ethical aims of philosophy had again become paramount. Partly, again, the analytical distinctness of Aristotle's manner brings into special prominence the difficulties that attend the Socratic effort to reconcile the ideal aspirations of men, and the principles on which they agree to distribute mutual praise and blame, with the principles on which their practical reasonings are commonly conducted. The conflict between these two elements of Common Sense was too profound to be compromised; and the moral consciousness of mankind demanded a more trenchant partisanship than Aristotle's. Its demands were met by a school which separated the moral from the worldly view of life, with an absoluteness and definiteness that caught the imagination; which regarded practical goodness as the highest result and manifestation of its ideal of wisdom; and which bound the common notions of duty into an apparently complete and coherent system, by a formula that comprehended the whole of human life, and exhibited its relation to the ordered process of the universe. This school was always known as the "Stoic," from the portico (στοά) in which its founder Zeno used to teach. The intellectual descent of its ethical doctrines is principally to be traced to Socrates through the Cynics, though an important element in them seems attributable to the school that inherited the "Academy" of Plato. Both Stoic and Cynic maintained, in its sharpest form, the fundamental tenet that the practical knowledge which is virtue, with the condition of soul that is inseparable from it, is alone to be accounted good. He who exercises this wisdom or knowledge has complete well-being; all else is indifferent to him. It is true that the Cynics were more concerned to emphasize the negative side of the sage's well-being, its independence of bodily health and strength, beauty, pleasure, wealth, good birth, good fame; while the Stoics brought into more prominence its positive side, the magnanimous confidence, the tranquillity undisturbed by grief, the joy and good cheer of the spirit, which inseparably attended the possession of wisdom. This difference, however, did not amount to disagreement. The Stoics, in fact, seem generally to have regarded the eccentricities of Cynicism as an emphatic manner of expressing the essential antithesis between philosophy and the world; a manner which, though not necessary or even normal, might yet be advantageously adopted by the sage under certain circumstances.[2]

Stoicism.

Wherein, then, does this knowledge or wisdom that makes free and perfect consist? Both Cynics and Stoics agreed that the most important part of it, that which constituted the fundamental distinction between the wise and the unwise, was the knowledge that the sole good of man lay in this knowledge or wisdom itself. It must be understood that by wisdom they meant wisdom realized in act; indeed, they did not conceive the existence of wisdom as separable from such realization. We may observe, too, that the Stoics rejected the divergence which we have seen gradually taking place in Platonic-Aristotelian thought from the position of Socrates, "that no one aims at what he knows to be bad." The stress that their psychology laid on the essential unity of the rational self that is the source of voluntary action, prevented them from accepting Plato's analysis of the soul into a regulative element and elements needing regulation. They held that what we call passion, so far as it governs the voluntary action of a reasoning being, must always be erroneous judgment as to what is to be sought or shunned. From such passions or errors the truly wise man will be free. He will of course be conscious of the solicitations of physical appetite; but he will not be misled into supposing that its object is really a good; he cannot, therefore, hope for the attainment of this object or fear to miss it, as these states involve the conception of it as a good. Similarly, though he will be subject like other men to bodily pain, this will not cause him mental grief or disquiet, as his worst agonies will not disturb his clear conviction that it is really indifferent to his true reasonable self. And so of all other objects that commonly excite men's hope, fear, joy, or grief; they cannot produce these states in the sage, because he cannot judge them to be good or bad. That this impassive sage was a being not to be found among living men the later Stoics at least were fully aware. They faintly suggested that one or two moral heroes of old time might have realized the ideal, but they admitted that all other philosophers (even) were merely in a state of progress towards it. This admission did not in the least diminish the rigor of their demand for absolute loyalty to the exclusive claims of wisdom. The assurance of its own unique value that such wisdom involved they held to be an abiding possession for those who had attained it;[3] and without this assurance no act could be truly wise or virtuous. Whatever was not of knowledge was of sin; and the distinction between right and wrong being absolute and not admitting of degrees, all sins were equally sinful; whoever broke the least commandment was guilty of the whole law. Similarly, in any one of the manifestations of wisdom, commonly distinguished as particular virtues, all wisdom was somehow involved; though whether these virtues were specifically distinct, or only the same knowledge in different relations, was a subtle question on which the Stoics do not seem to have been agreed.

Was, then, this rare and priceless knowledge something which it was possible for man to attain, or were human shortcomings really involuntary? There is an obvious danger to moral responsibility involved in the doctrine that vice is involuntary; which yet seems a natural inference from the Socratic identification of knowledge with virtue. Hence Aristotle had already been led to attempt a refutation of this doctrine; but his attempt had only shown the profound difficulty of attacking the paradox, so long as it was admitted that no one could of deliberate purpose act contrary to what seemed to him best. Now, Aristotle's divergence from Socrates had not led him so far as to deny this; while for the Stoics who had receded to the original Socratic position, the difficulty was still more patent. In fact, a philosopher who maintains that virtue is essentially knowledge has to choose between alternative paradoxes; he must either allow vice to be involuntary, or affirm ignorance to be voluntary. The latter horn of the dilemma is at any rate the less dangerous to morality, and as such the Stoics chose it. But they were not yet at the end of their perplexities; for while they were thus driven on one line of thought to an extreme extension of the range of human volition, their view of the physical universe involved an equally thorough-going determinism. How could the vicious man be responsible if his vice were strictly predetermined? The Stoics answered that the error which was the essence of vice was so far voluntary that it could be avoided if men chose to exercise their reason; no doubt it depended on the innate force and firmness[4] of a man's soul whether his reason was thus effectually exercised; but moral responsibility was saved if the vicious act proceeded from the man himself and not from any external cause.

With all this we have got little way towards ascertaining the positive practical content of this wisdom. How are we to emerge from the barren circle of affirming (1) that wisdom is the sole good and unwisdom the sole evil, and (2) that wisdom is the knowledge of good and evil; and attain some method for determining the particulars of good conduct? Both Cynicism and Stoicism stood in need of such a method to complete their doctrine, since neither school was prepared to maintain that what the sage does is indifferent (no less than what befalls him), provided only he does it with a full conviction of its indifference. The Cynics, however, seem to have made no philosophical provision for this need; they were content to mean by virtue what any plain man meant by it, except in so far as their sense of independence led them to reject certain received precepts and prejudices. The Stoics, on the other hand, not only worked out a detailed system of duties—or, as they termed them, "things meet and fit" (*καθήκοντα*) for all occasions of life; they were further especially concerned to comprehend them under a general formula. They found this by bringing out the positive significance of the notion of Nature, which the Cynic had used chiefly in a negative way, as an antithesis to the "consentions" (*νόμος*), from which his knowledge had made him free. Even in this negative use of the notion, it is necessarily implied that whatever in man is "natural"—that is, prior to and uncorrupted by social customs and conventions, —must furnish valid guidance for conduct. But whence can this authority belong to the natural, unless nature, the ordered creation of which man is a part, be itself somehow reasonable, an expression or embodiment of divine law and wisdom? The conception of the world, as organized and filled by divine thought, was common, in some form, to all the philosophies that looked back to Socrates as their founder,—the Megarians, as we saw, even maintaining that this thought was the sole reality. This latter doctrine harmonized thoroughly with the Stoic view of human good; but being unable to conceive substance idealistically, they (with considerable aid from the earlier system of Heraclitus) supplied a materialistic side to their pantheism,—conceiving divine thought as an attribute of the purest and most primary of material substances, a subtle fiery æther. They held the physical world to have been developed out of Zeus, so conceived; to be, in fact, a modification of his eternal substance into which it would ultimately be consumed and re-absorbed; meanwhile it was throughout permeated with the fashioning force of his divine spirit, and perfectly ordered by his prescient law. This theological view of the physical universe had a double effect on the ethics of the Stoic. In the first place it gave to his cardinal conviction of the all-sufficiency of wisdom for human well-being a root of cosmical fact, and an atmosphere of religious and social emotion. The exercise of wisdom was now viewed as the pure life of that particle of divine substance which was in very truth the "god within him;" the reason whose supremacy he maintained was the reason of Zeus, and of all gods and reasonable men, no less than his own; its realization in any one individual was thus the common good of all rational beings as such; "the sage could not stretch out a finger rightly without thereby benefiting all other sages,"—nay, it might even be said that he was "as useful to Zeus as Zeus to him."[1] But again, the same conception served to harmonize the higher and the lower elements of human life. For even in the physical or non-rational man, as originally constituted, we may see clear indications of the divine design, which it belongs to his rational will to carry into conscious execution; indeed, in the first stage of human life, before reason is fully developed, uncorrupted natural impulse effects what is afterwards the work of reason. Thus the formula of "living according to nature," in its application to man as the "rational animal," may be understood both as directing that reason is to govern, and as indicating how that government is to be practically exercised. In man, as in every other animal, from the moment of birth natural impulse prompts to self-preservation, and to the maintenance of his physical frame in its original integrity; then, when reason has been developed and has recognized itself as its own sole good, these "primary ends of nature" and whatever promotes these still constitute the outward objects at which reason is to aim; there is a certain value (*ἀξία*) in them, in proportion to which they are "preferred" (*προηγμένα*) and their opposites "rejected" (*ἀποπροηγμένα*); indeed, it is only in the due and consistent exercise of such preference and rejection that wisdom can find its practical manifestation. In this way all or most of the things commonly judged to be "goods"—health, strength wealth, fame,[2] etc.—are brought within the sphere of the sage's choice, though his real good still is solely in the wisdom of the choice, and not in the thing chosen; just as an archer aims at a bull's eye, his end being not the mark itself, but the manifestation of his skill in hitting it.

---

[1] The term is derived from περιπατεῖν, "to walk about," and was applied to the disciples of Aristotle in consequence of the master's custom of giving instruction while walking to and fro in the shady avenues of the gymnasium where he lectured.

[2] It has been suggestively said that Cynicism was to Stoicism what monasticism was to early Christianity. The analogy, however, must not be pressed too far, since orthodox Stoics do not ever seem to have regarded Cynicism as the more perfect way.

[3] The Stoics were not quite agreed as to the inalienability of virtue, but they were agreed that, when once possessed, it could only be lost through the loss of reason itself.

[4] Hence some members of the school, without rejecting the definition of virtue = knowledge, also defined it as "strength and force."

It is to be observed that the adoption of "conformity to nature," as the general positive rule for outward conduct, originated in the Academic school, which, after Plato's death, seems to have separated ethics from ontology as completely as Aristotle. We find "nature" used as a cardinal notion in ethics both by Speusippus, Plato's immediate successor, and by Xenocrates, the contemporary of Aristotle. Indeed, their fundamental doctrine apparently differed from the Stoic's in calling "good" what the latter called "preferred," and consistently affirming that virtue was sufficient by itself for happiness, but not for perfect happiness. A view nearly the same, but allowing more importance to outward circumstances, was maintained by the Peripatetics; on whom, when the energies of Plato's school were absorbed in scepticism (250–100 B.C.), it chiefly devolved to maintain the more moderate[3] claims of morality in contrast to the paradoxes of Stoicism. It is easy to understand how the one school thought it mere perversity to refuse the common names of "good" and "evil" to things "preferred" and "rejected," and patent inconsistency to make wisdom manifest itself in choosing among objects that wisdom knew to be indifferent; while to the other it seemed the essence of philosophy to be thus independent of outward things while yet exercised upon them.

So far we have considered the "nature" of the individual man as apart from his social relations; but it is obvious that the sphere of virtue, as commonly conceived, lies chiefly in these, and this was fully recognized in the Stoic account of duties (*καθήκοντα*); indeed, their exposition of the "natural" basis of justice, the evidences in man's mental and physical constitution that he was born not for himself but for mankind, is the most important part of their work in the region of practical morality. Here, however, we especially notice the double significance of "natural," as applied to (1) what actually exists everywhere or for the most part, and (2) what would exist if the original plan of man's life were fully carried out; and we find that the Stoics have not clearly harmonized the two elements of the notion. That man was "naturally" a social animal Aristotle had already taught; that all rational beings, in the unity of the reason that is common to all, form naturally one community with a common law was (as we saw) an immediate inference from the Stoic conception of the universe as a whole. That the members of this "city of Zeus" should observe their contracts, abstain from mutual harm, combine to protect each other from injury, were obvious points of natural law; while, again, it was clearly necessary to the preservation of human society that its members should form sexual unions, produce children, and bestow care on their rearing and training. But beyond this nature did not seem to go in determining the relations of the sexes; accordingly, we find that community of wives was a feature of Zeno's ideal commonwealth, just as it was of Plato's; and other Stoics are represented as maintaining, and illustrating with rather offensive paradoxes, the conventionality and relativity of the received code of sexual morality; while, again, the strict theory of the school recognized no government or laws as true or binding except those of the sage; he alone is the true ruler, the true king. So far, the Stoic "nature" seems in danger of being as revolutionary as Rousseau's. Practically, however, this revolutionary aspect of the notion was kept for the most part in the background; the rational law of an ideal community was peacefully undistinguished from the positive ordinances and customs of actual society; and the "natural" ties that actually bound each man to family, kinsmen, fatherland, and to unwise humanity generally, supplied the outline on which the external manifestation of justice was delineated. It was a fundamental maxim that the sage was to take part in public life; and it does not appear that his political action was to be regulated by any other principles than those commonly accepted in his community. Similarly, in the view taken by the Stoics of the duties of social decorum, and in their attitude to the popular religion, we find a fluctuating compromise between the disposition to repudiate what is artificial and conventional, and the disposition to revere what is actual and established, which both equally spring from the very core of their creed.

---

[1] It is apparent in view of this union in reason of rational beings that friends are allowed to be "external goods" to the sage, and that the possession of good children is also counted a good.

[2] The Stoics seem to have varied in their view of "good repute," *εὐδοξία* at first, when the school was more under the influence of Cynicism, they professed an outward as well as an inward indifference to it; ultimately they conceded the point to common sense, and included it among *προηγμένα*.

[3] There were different degrees of this moderation, but in no case was it very moderate;—if we may judge from the extent to which Aristotle's successor Theophrastus was attacked for his weakness in conceding that there was a degree of torture which would prevent a good man from being happy.

Stoics and hedonists.

Among the primary ends of nature, in which wisdom recognized a certain preferability, the Stoics included freedom from bodily pain; but they refused, even in this outer court of wisdom, to find a place for pleasure. They held that the latter was not an object of uncorrupted natural impulse, but an "aftergrowth," a mere consequence of natural impulses attaining their ends. They thus endeavored to resist Epicureanism even on the ground where the latter seems *prima facie* strongest; in its appeal, namely, to the natural pleasure-seeking of all living things. Nor did they merely mean by pleasure (*ἡδονή*) the gratification of bodily appetite; we find (*e.g.*) Chrysippus urging, as a decisive argument against Aristotle that pure speculation was "a kind of amusement; that is, pleasure." This being so, the distinction that they drew between pleasure, and the "joy and gladness" (*χαρά εὐφροσύνη*) that accompanied the exercise of virtue, cannot but seem somewhat arbitrary. We must observe, however, that even this "moral pleasure," as a modern would consider it, though inseparable in the Stoic view from well-being, was not its most essential constituent. It is only by a modern misrepresentation of Stoicism that tranquillity or serenity of soul is taken as the real ultimate end, to which the exercise of virtue is merely a means. In Zeno's system, as in Aristotle's, it is good activity, and not the feeling that attends it, which constitutes the essence of good life. At the same time, since pleasant feeling of some kind must always have been the chief element in the common conception of Greek *εὐδαιμονία* as well as of English "happiness," it is probable that the serene joys of virtue and the griefiessness which the sage was conceived to maintain amid the worst tortures, formed the main attractions of Stoicism for ordinary minds. In this sense it may be fairly said that Stoics and Epicureans made rival offers to mankind of the same kind of happiness; and the philosophical peculiarities of either system may be equally traced to the same desire of maintaining that independence of the changes and chances of life which seemed essential to a settled serenity of soul. The Stoic claims on this head were the loftiest; as the well-being of their sage was independent, not only of external things and bodily conditions, but of time itself; it was fully realized in a single exercise of wisdom and could not be increased by duration. This paradox is violent, but it is quite in harmony with the spirit of Stoicism; and we are more startled to find that the Epicurean sage, no less than the Stoic, is to be happy even on the rack; that his happiness, too, is unimpaired by being restricted in duration, when his mind has apprehended the natural limits of life; that, in short, Epicurus makes no less strenuous efforts than Zeno to eliminate imperfection from the conditions of human existence. This characteristic, however, is the key to the chief differences between Epicureanism and the more naïve hedonism of Aristippus. The latter system gave the simplest and most obvious answer to the inquiry after ultimate good for man; but besides being liable, when developed consistently and unreservedly, to offend the common moral consciousness, it conspicuously failed to provide the "completeness" and "security" which, as Aristotle says, "one divines to belong to man's true Good." Philosophy, in the Greek view, should be the art as well as the science of good life; and hedonistic philosophy would seem a bungling and uncertain art of pleasure, as pleasure is ordinarily conceived. Nay, it would even be found that the habit of philosophical reflection often operated adversely to the attainment of this end, by developing the thinker's self-consciousness, so as to disturb that normal relation to external objects on which the zest of ordinary enjoyment depends. Hence we find that later thinkers of the Cyrenaic school felt themselves compelled to change their fundamental notion; thus Theodorus defined the good as "gladness" (*χαρά*) depending on wisdom, as distinct from mere pleasure, while Hegesias proclaimed that happiness was unattainable, and that the chief function of wisdom was to render life painless by producing indifference to all things that give pleasure. But by such changes their system lost the support that it had had in the pleasure-seeking tendencies of ordinary men; indeed, with Hegesias the pursuit of pleasure has turned into its opposite, and one is not surprised to learn that this hedonist's lectures were forbidden as stimulating to suicide. It was clear that if philosophic hedonism was to be established on a broad and firm basis, it must somehow combine in its notion of good what the plain man naturally sought with what philosophy could plausibly offer. Such a combination was effected, with some little violence, by Epicurus; whose system with all its defects showed a remarkable power of standing the test of time, as it attracted the unqualified adhesion of generation after generation of disciples for a period of more than six centuries.

Epicurus.

Epicurus maintains, on the one hand, as emphatically as Aristippus, that pleasure is the sole ultimate good, and pain the sole evil; that no pleasure is to be rejected except for its painful consequences, and no pain to be chosen except as a means to greater pleasure; that the stringency of all laws and customs depends solely on the legal and social penalties attached to their violation; that, in short, all virtuous conduct and all speculative activity are empty and useless, except as contributing to the pleasantness of the agent's life. And he assures us that he means by pleasure what plain men mean by it; and that if the gratifications of appetite and sense are discarded, the notion is emptied of its significance. So far the system would seem to suit the inclinations of the most thorough-going voluptuary. But its aspect changes when we learn that the highest point of pleasure, whether in body or mind, is to be attained by the mere removal of pain or disturbance, after which pleasure admits of variation only and not of augmentation; that therefore the utmost gratification of which the body is capable may be provided by the simplest means, and that "natural wealth" is no more than any man can earn. When further we are told that the attainment of happiness depends almost entirely upon insight and right calculation, fortune having very little to do with it; that the pleasures and pains of the mind are far more important than those of the body, owing to the accumulation of feeling caused by memory and anticipation; and that an indispensable condition of mental happiness lies in relieving the mind of all superstitions, which can only be effected by a thorough knowledge of the physical universe,—we see that an ample place is secured in this system for the exercise of the philosophic intellect. So again, in the stress that Epicurus lays on the misery which the most secret wrong-doing must necessarily cause the doer, from the perpetual fear of discovery, and in his exuberant exaltation of the value of disinterested friendship, we recognize a sincere, though not completely successful, effort to avoid the offence that consistent egoistic hedonism is apt to give to ordinary human feeling. As regards friendship, indeed, the example of Epicurus, who was a man of eager and affectionate temperament, and peculiarly unexclusive sympathies,[1] was probably more effective than his teaching. The genial fellowship of the philosophic community that he collected in his garden remained a striking feature in the traditions of his school; and certainly the ideal which Stoics and Epicureans equally cherished, of a brotherhood of sages united in harmonious smooth-flowing existence, was most easily realized on the Epicurean plan of withdrawing from political and dialectical conflict to simple living and serene leisure, in imitation of the eternal leisure of the gods apart from the fortuitous concourse of atoms that we call a world.

Later Greek philosophy. Stoicism in Rome.

The two systems that have just been described were those that most prominently attracted the attention of the ancient world, so far as it was directed to ethics, from their almost simultaneous origin to the end of the 2d century A.D., when Stoicism almost vanishes from our view. But side by side with them the schools of Plato and Aristotle still maintained a continuity of tradition, and a more or less vigorous life; and philosophy, as a recognized element of Græco-Roman culture, was understood to be divided among these four branches. The internal history, however, of the four schools was very different. We find no development worthy of notice in Aristotelian ethics; in fact the philosophic energy of this school seems to have been somewhat weighed down by the inheritance of the master's vast work, and distracted by the example of his many-sided activity. The Epicureans, again, from their unquestioning acceptance of the "dogmas"[1] of their founder, almost deserve to be called a sect rather than a school. On the other hand, the changes in Stoicism are very noteworthy; and we are peculiarly well able to trace them, as the only original writings of this school which we possess are those of the later Roman Stoics. These changes may be partly attributed to the natural inner development of the system, partly to the reaction of the Roman mind on the essentially Greek doctrine which it received,—a reaction all the more inevitable from the very affinity between the Stoic sage and the ancient Roman ideal of manliness. It was natural that the earlier Stoics should be chiefly occupied with delineating the inner and outer characteristics of ideal wisdom and virtue, and that the gap between the ideal sage and the actual philosopher, though never ignored, should yet be somewhat overlooked. But when the question "What is man's good?" had been answered by an elaborate exposition of perfect wisdom, the other question "How may a man emerge from the misery and folly of the world, and get on the way towards wisdom?" would naturally attract attention; and the preponderance of moral over scientific interest, which was characteristic of the Roman mind, would tend to give this question especial prominence. Thus philosophy, in the view of Seneca and Epictetus, comes to present itself as the healer to whom men come from a sense of their weakness and disease,—whose business is "with the sick not with the whole;" the wisdom by which she heals is not something that needs long dissertations or dialectical subtleties, but rather continual practice, self-discipline, self-examination. The same sense of the gap between theory and fact gives to the religious element of Stoicism a new force and a new aspect; the soul, conscious of its weakness, leans on the thought of God, and in the philosopher's attitude towards external events, pious resignation preponderates over self-poised indifference; the old self-reliance of the reason, looking down on man's natural life as a mere field for its exercise, shrinks and dwindles, making room for a positive aversion to the flesh as an alien element imprisoning and hampering the spirit; the body has come to be a "corpse which the soul sustains,"[2] and the life a "sojourn in a strange land;"[3] in short the ethical idealism of Zeno has begun to borrow from the metaphysical idealism of Plato.

---

[1] It is noted of him that he did not disdain the co-operation either of women or of slaves in his philosophical labors.

History of Plato's school.

In no one of these schools was the outward coherence of tradition so much strained by inner changes as it was in Plato's. The alterations, however, in the metaphysical position of the Academics seem to have had less effect on their ethical teaching than might be expected, as, even during the period of Scepticism, they appear to have presented as probable the same general view of human good which Antiochus afterwards dogmatically announced as a revival of the common doctrine of the "ancients"—Plato and Aristotle. And during the eventful period of a century and a half that intervenes between Antiochus and Plutarch, we may suppose the school to have maintained the old controversy with Stoicism on much the same ground; accepting the formula of "life according to nature," but demanding that the "good" of man should refer to his nature as a whole, the good of his rational part being the chief element, and always preferable in case of conflict, but yet not absolutely his sole good. When, however, we have come to Plutarch, the same tendencies of change show themselves that we have noticed in later Stoicism. The conception of a normal harmony between the higher and lower elements of human life has begun to be disturbed, and the side of Plato's teaching that deals with the inevitable imperfections of the world of concrete experience becomes again prominent. For example, we find Plutarch adopting and amplifying the suggestion in Plato's latest treatise (the *Laws*) that this imperfection is due to a bad world-soul that strives against the good,—a suggestion which is alien to the general tenor of Plato's doctrine, and had consequently lain unnoticed during the intervening centuries. We observe, again, the value that Plutarch attaches, not merely to the sustainment and consolation of rational religion, but to the supernatural communications vouchsafed by the divinity to certain human beings in certain states,—as in dreams, through oracles, or by special warnings, like those of the genius of Socrates. For these flashes of intuition, he holds, the soul should be prepared by tranquil repose, and the subjugation of sensuality through abstinence. The same estrangement between mind and matter, the same ascetic effort to attain by aloofness from the body a pure receptivity for divine or semi-divine influences, is exhibited in the revived Pythagoreanism of the first and second centuries A. D. But the general tendency that we are noting did not find its full expression in a reasoned philosophical system until we come to the latest-born of the great thinkers of antiquity—the Egyptian Plotinus.

Neo-Platonism.

The system of Plotinus (205–270 A.D.) is a striking development of that element of Platonism which has had most fascination for the mediæval and even for the modern mind, but which had almost vanished out of sight for six centuries. At the same time the differences between this Neo-Platonism and the original Platonism are all the more noteworthy from the reverent adhesion to the latter which the former always maintains. Plato, we saw, identified good with the real essence of things; and this, again, with that in them which is definitely conceivable and knowable. It belongs to this view to regard the imperfection or badness of things as somewhat devoid of real being, and so incapable of being definitely thought or known; accordingly, we find that Plato has no technical term for that in the concrete sensible world which hinders it from perfectly expressing the abstract ideal world, and which in Aristotle's system is distinguished as absolutely formless matter (ὕλη). And so, when we pass from the ontology to the ethics of Platonism, we find that, though the highest life is only to be realized by turning away from concrete human affairs and their material environment, still the sensible world is not yet an object of positive moral aversion; it is rather something which the philosopher is seriously concerned to make as harmonious, good, and beautiful as possible. But in Neo-Platonism the inferiority of the condition in which the embodied human soul finds itself is more intensely and painfully felt; hence an express recognition of formless matter (ὕλη) as the "first evil," from which is derived the "second evil," body (σῶμα), to whose influence all the evil in the soul's existence is due. Accordingly the ethics of Plotinus represent, we may say, the moral idealism of the Stoics cut loose from nature. The only good of man is the pure existence of the soul, which in itself, apart from the contagion of the body, is perfectly free from error or defect; all higher or philosophic virtues (as distinguished from the merely "civic" forms of prudence, temperance, justice, and courage) are essentially purifications from this contagion; until the highest mode of goodness is reached, in which the soul has no community with the body, and is entirely turned towards reason. It should be observed that Plotinus himself is still too Platonic to hold that the absolute mortification of natural bodily appetites is required for purifying the soul; but this ascetic inference was drawn to the fullest extent by his disciple Porphyry.

There is, however, a yet higher point to be reached in the upward ascent of the Neo-Platonist from matter; and here the divergence of Plotinus from Platonic idealism is none the less striking, because it can to some extent support itself on Platonic authority.[4] The cardinal assumption of Plato's metaphysic is, that the real is definitely thinkable and knowable in proportion as it is real; so that the further the mind advances in abstraction from sensible particulars and apprehension of real being, the more definite and clear its thought becomes. Plotinus, however, urges that, as all thought involves difference or duality of some kind, it cannot be the primary fact in the universe, what we call God. He must be an essential unity prior to this duality, a Being wholly without difference or determination; and, accordingly, the highest mode of human existence, in which the soul apprehends this absolute, must be one in which all definite thought is transcended, and all consciousness of self lost in the absorbing ecstasy. Porphyry tells us that his master Plotinus attained the highest state four times during the six years which he spent with him.

Neo-Platonism is originally Alexandrine, and more than a century of its existence has elapsed before we find it flourishing on the old Athenian soil. Hence it is often regarded as Hellenistic rather than Hellenic, a product of the mingling of Greek with Oriental civilization. But however Oriental may have been the cast of mind that eagerly embraced the theosophic and ascetic views that have just been described, the forms of thought by which these views were philosophically reached are essentially Greek; and it is by a thoroughly intelligible process of natural development, in which the intensification of the moral consciousness represented by Stoicism plays an important part, that the Hellenic pursuit of knowledge culminates in a preparation for ecstasy, and the Hellenic idealization of man's natural life ends in a settled antipathy to the body and its works. At the same time we ought not to overlook the affinities between the doctrine of Plotinus and that remarkable combination of Greek and Hebrew thought which Philo Judæus had expounded two centuries before; nor the fact that Neo-Platonism was developed in conscious antagonism to the new religion which had spread from Judea, and was already threatening the conquest of the Græco-Roman world, and also to those fantastic hybrids of Christianity and later paganism, the Gnostic systems; nor, finally, that it furnished the chief theoretical support in the last desperate struggle that was made under Julian to retain the old polytheistic worship. To the new world of thought, that after the failure of this struggle was definitely established upon the ruins of the old, we have now to turn.

---

[1] The last charge of Epicurus to his disciples is said to have been, Τῶν δογμάτων μεμνῆσθαι.

[2] Epictetus.

[3] Marcus Aurelius.

[4] The ultimate notion in Plato's ontology is, as we saw, the "good;" and hence he is led to describe this good as "beyond thought and being" (ἐπέκεινα νοῦ καὶ οὐσίας). The phrase might certainly suggest the metaphysical doctrine of Plotinus, though we cannot suppose that his theosophic inference presented itself even dimly to the mind of Plato.

III. Christianity and Mediæval Ethics.—In the present article we are not concerned with the origin of the Christian religion, nor with its outward history; the causes of its resistless development during the first three centuries; its final triumph over paganism; its failure to check the decay of the Hellenistic civilization that centred in Constantinople, or to withstand in the east and south the force of the new religious movement that burst from Arabia in the 7th century; its success in dominating the social chaos to which the barbarian invasions reduced the Western empire; the important part it took in educing from this chaos the new civilized order to which we belong; the complex and varying relations in which it has since stood to the political organizations, the social life, the progressive science, the literary and artistic culture of our modern world. Nor have we to consider the special doctrines that have formed the bond of union of the Christian communities in any other than their ethical aspect, their bearing on the systematization of human aims and activities. This aspect, however, must necessarily be prominent in discussing Christianity, which cannot be adequately treated if considered merely as a system of theological beliefs divinely revealed, and special observances divinely sanctioned; as it essentially claims to rule the whole man, and leave no part of his life out of the range of its regulating and transforming influences. It was not till the 4th century A.D. that the first attempt was made to offer anything like a systematic exposition of Christian morality; and nine centuries more had passed away before a genuinely philosophic intellect, trained by a full study of the greatest Greek thinker, undertook to give complete scientific form to the ethical doctrine of the Catholic church. Before, however, we take a brief survey of the progress of systematic ethics from Ambrose to Thomas Aquinas, it may be well to examine the chief features of the new moral consciousness that had spread through Græco-Roman civilization, and was awaiting philosophic synthesis. In making this examination it will be convenient to consider first the new *form* or universal characteristics of Christian morality, and afterwards to note the chief points in the *matter* or particulars of duty and virtue which received an important development or emphasis from the new religion.

Christian and Jewish "law of God."

The first point to be noticed is the new conception of morality as the positive law of a theocratic community, possessing a written code imposed by divine revelation, and sanctioned by express divine promises and threatenings. It is true that we find in ancient thought, from Socrates downwards, the notion of a law of God, eternal and immutable, partly expressed and partly obscured by the various and shifting codes and customs of actual human societies. But the sanctions of this law were vaguely and, for the most part, feebly imagined; its principles were essentially unwritten and unpromulgated, and thus not referred to the external will of an Almighty Being who claimed unquestioning submission, but rather to the reason that gods and men shared, by the exercise of which alone they could be adequately known and defined. Hence, even if the notion of law had been more prominent than it was in ancient ethical thought, it could never have led to a juridical, as distinct from a philosophical, treatment of morality. In Christianity, on the other hand, we early find that the method of moralists determining right conduct is to a great extent analogous to that of jurisconsults interpreting a code. It is assumed that divine commands have been implicitly given for all occasions of life, and that they are to be ascertained in particular cases by interpretation and application of the general rules obtained from texts of Scripture, and by analogical inference from scriptural examples. This juridical method descended naturally from the Jewish theocracy, of which Christendom was a universalization. Moral insight, in the view of the most thoughtful Jews, was essentially knowledge of the divine law, to which practical efficacy was given by trust in God's promises and fear of His judgments; this law having been partly written and promulgated by Moses, partly revealed in the fervid utterances of the later prophets, partly handed down through oral tradition from immemorial antiquity, and having further, before Judaism gave birth to Christianity, received an extensive development through the commentaries and supplementary maxims of several generations of students. Christianity inherited the notion of a written divine code acknowledged as such by the "true Israel"—now potentially including the whole of mankind, or at least the chosen of all nations,—on the sincere acceptance of which the Christian's share of the divine promises to Israel depended. And though the ceremonial part of the old Hebrew code was altogether rejected, and with it all the supplementary jurisprudence resting on tradition and erudite commentary, still God's law was believed to be contained in the sacred books of the Jews, supplemented by the records of Christ's teaching and the writings of his apostles. By the recognition of this law the church was constituted as an ordered community, essentially distinct from the state; the distinction between the two was sharpened and hardened by the withdrawal of the early Christians from civic life, to avoid the performance of idolatrous ceremonies imposed as official expressions of loyalty, and by the persecutions which they had to endure, when the spread of an association apparently so hostile to the framework of ancient society had at length caused the imperial government serious alarm. Nor was the antithesis obliterated by the recognition of Christianity as the state religion under Constantine. The law of God and its interpreters still remained quite distinct from the secular law and jurists of the Roman empire; though the former was of course binding on all mankind, the church was none the less a community of persons who regarded themselves as both specially pledged and specially enabled to obey it,—a community, too, that could not be entered except by a solemn ceremony typifying a spiritual new birth.

Thus the fundamental difference between morality and (human) legality only came out more clearly in consequence of the jural form in which the former was conceived. The ultimate sanctions of the moral code were the infinite rewards and punishments awaiting the immortal soul hereafter; but the church early felt the necessity of withdrawing the privileges of membership from persons guilty of grave offences, and only allowing them to be gradually regained by a solemn ceremonial expressive of repentance, protracted through several years; while in the case of still graver sins this exclusion lasted till death, or was even made absolute. For minor offences, again, all Christians were called upon to express penitence ceremonially, by fasting and abstinence from permitted pleasures, as well as verbally in public and private devotions. "Excommunication" and "penance" thus came to be temporal ecclesiastical sanctions of the moral law; as the graduation of these sanctions naturally became more careful and minute, a correspondingly detailed classification of offences was rendered necessary; the regulations for observing the ordinary fasts and festivals of the church became similarly elaborate; and thus a system of ecclesiastical jurisprudence, prohibitive and ceremonial, was gradually produced, somewhat analogous to that of the rejected Judaism. At the same time this tendency to develop and make prominent a scheme of external duties has always been balanced and counteracted in Christianity by the ineffaceable remembrance of its original antithesis to Jewish legalism. We find that this antithesis, as fantastically understood and exaggerated by some of the Gnostic sects of the 2d and 3d centuries A.D., led, not merely to theoretical antinomianism, but even (if the charges of their orthodox opponents are not entirely to be discredited) to gross immorality of conduct. A similar tendency has shown itself at other periods of church history. And though such antinomianism has always been sternly repudiated by the moral consciousness of Christendom, it has never been forgotten that "inwardness," rightness of heart or spirit, is the special and pre-eminent characteristic of Christian goodness. It must not, of course, be supposed that the need of something more than mere fulfilment of external duty was ignored even by the later Judaism. Rabbinic erudition could not forget the repression of vicious desires in the tenth commandment, the stress laid in Deuteronomy on the necessity of heartfelt and loving service to God, or the inculcations by later prophets of humility and faith. "The real and only Pharisee," says the Talmud, "is he who does the will of his Father because he loves Him." But it remains true that the contrast with the "righteousness of the scribes and Pharisees" has always served to mark the requirement of "inwardness" as a distinctive feature of the Christian code,—an inwardness not merely negative, tending to the repression of vicious desires as well as vicious acts, but also involving a positive rectitude of the inner state of the soul.

Christian and Pagan inwardness.

In this aspect Christianity invites comparison with Stoicism, and indeed with pagan ethical philosophy generally, if we except the hedonistic schools. Rightness of purpose, preference of virtue for its own sake, suppression of vicious desires, were made essential points by the Aristotelians, who attached the most importance to outward circumstances in their view of virtue, no less than by the Stoics, to whom all outward things were indifferent. The fundamental differences between pagan and Christian ethics do not depend on any difference in the value set on rightness of heart or purpose, but on different views of the essential form or conditions of this inward rightness. In neither case is it presented purely and simply as moral rectitude. By the pagan philosophers it was always conceived under the form of Knowledge or Wisdom, it being inconceivable to all the schools sprung from Socrates that a man could truly know his own good and yet deliberately choose anything else. This knowledge, as Aristotle held, might be permanently precluded by vicious habits, or temporarily obliterated by passion, but if present in the mind it must produce rightness of purpose. Or even if it were held with some of the Stoics that true wisdom was out of the reach of the best men actually living, it none the less remained the ideal condition of perfect human life; though all actual men were astray in folly and misery, knowledge was none the less the goal towards which the philosopher progressed, the realization of his true nature. By Christian evangelists and teachers, on the other hand, the inner springs of good conduct were generally conceived as Faith and Love.

Faith.

Of these notions the former has a somewhat complex ethical import; it seems to blend several elements differently prominent in different minds. Its simplest and commonest meaning is that emphasized in the contrast of "faith" with "sight;" where it signifies belief in the invisible divine order represented by the church, in the actuality of the law, the threats, the promises of God, in spite of all the influences in man's natural life that tend to obscure this belief. Out of this contrast there ultimately grew an essentially different opposition between faith and knowledge or reason, according to which the theological basis of ethics was contrasted with the philosophical; the theologians maintaining sometimes that the divine law is essentially arbitrary, the expression of will, not reason; more frequently that its reasonableness is inscrutable, and that actual human reason should confine itself to examining the credentials of God's messengers, and not the message itself. But in early Christianity this latter antithesis was as yet undeveloped; faith means simply force in clinging to moral and religious conviction, whatever their precise rational grounds may be; this force, in the Christian consciousness, being inseparably bound up with personal loyalty and trust towards Christ, the leader in the battle with evil that is being fought, the ruler of the kingdom to be realized. So far, however, there is no ethical difference between Christian faith and that of Judaism, or its later imitation, Mahometanism; except that the personal affection of loyal trust is peculiarly stirred by the blending of human and divine natures in Christ, and the rule of duty impressively taught by the manifestation of His perfect life. A more distinctively Christian, and a more deeply moral, significance is given to the notion in the antithesis of "faith" and "works." Here faith means more than loyal acceptance of the divine law and reverent trust in the lawgiver; it implies a consciousness, at once continually present and continually transcended, of the radical imperfection of all human obedience to the law, and at the same time of the irremissible condemnation which this imperfection entails. The Stoic doctrine of the worthlessness of ordinary human virtue, and the stern paradox that all offenders are equally, in so far as all are absolutely, guilty, find their counterparts in Christianity; but the latter, while maintaining this ideal severity in the moral standard, with an emotional consciousness of what is involved in it quite unlike that of the Stoic, at the same time overcomes its practical exclusiveness through faith. This faith, again, may be conceived in two modes, essentially distinct though usually combined. In one view it gives the believer strength to attain, by God's supernatural aid or "grace," a goodness of which he is naturally incapable; in another view it gives him an assurance that, though he knows himself a sinner deserving of utter condemnation, a perfectly just God still regards him with favor on account of the perfect services and suffering of Christ. Of these views the former is the more catholic, more universally present in the Christian consciousness; the latter more deeply penetrates the mystery of the atonement, as learnt by the chief Protestant churches from the Pauline epistles.

Love.

But faith, however understood, is rather an indispensable pre-requisite than the essential motive principle of Christian good conduct. This is supplied by the other central notion, love. On love depends the "fulfilling of the law," and the sole moral value of Christian duty—that is, on love to God, in the first place, which in its fullest development must spring from Christian faith; and, secondly, love to all mankind, as the objects of divine love and sharers in the humanity ennobled by the incarnation. This derivative philanthropy, whether conceived as mingling with and intensifying natural human affection, or as absorbing and transforming it, characterizes the spirit in which all Christian performance of social duty is to be done; loving devotion to God being the fundamental attitude of mind that is to be maintained throughout the whole of the Christian's life.

Purity.

But further, as regards abstinence from unlawful acts and desires prompting to them, we have to notice another form in which the inwardness of Christian morality manifests itself, which, though less distinctive, should yet receive attention in any comparison of Christian ethics with the view of Græco-Roman philosophy. The profound horror with which the Christian's conception of a suffering as well as an avenging divinity tended to make him regard all condemnable acts was tinged with a sentiment which we may perhaps describe as a ceremonial aversion moralized,—the aversion, that is, to foulness or impurity. In all religions to some extent, but especially in Oriental religions, the natural dislike of material defilement has been elevated into a religious sentiment. In Judaism, in particular, we find it used to support a complicated system of quasi-sanitary abstinences and ceremonial purifications; at the same time, as the ethical element predominated in the Jewish religion, a moral symbolism was felt to reside in the ceremonial code, and thus aversion to impurity came to be a common form of the ethico-religious sentiment. Then, when Christianity threw off the Mosaic ritual, this religious sense of purity was left with no other sphere besides morality; while, from its highly idealized character, it was peculiarly well adapted for that repression of vicious desires which Christianity claimed as its special function.

Distinctive particulars of Christian morality.

When we examine the details of Christian morality, we find that most of its distinctive features are naturally connected with the more general characteristics just stated; though many of them may also be referred directly to the example and precepts of Christ, and in several cases they are clearly due to both causes, inseparably combined. We may notice, in the first place, that the conception of morality as a code which, if not in itself arbitrary, is yet to be accepted by men with unquestioning submission, tends naturally to bring into prominence the virtue of obedience to authority; just as the philosophic view of goodness as the realization of reason gives a special value to self-determination and independence (as we see more clearly in the post-Aristotelian schools, where ethics is distinctly separated from politics). Again, the opposition between the natural world and the spiritual order into which the Christian had been born anew led not merely to a contempt equal to that of the Stoic for wealth, fame, power, and other objects of worldly pursuit, but also, for some time at least, to a comparative depreciation of the domestic and civic relations of the natural man; while a keen sense of man's impotence to make this disengagement of the spirit complete induced the same hostility to the body as a clog and hinderance, that we find to some extent in Plato, but more fully developed in Neo-Platonism, Neo-Pythagoreanism, and other products of the mingling of Greek with Oriental thought. This latter feeling is exhibited in the value set on fasting in the Christian church from the earliest times, and in an extreme form in the self-torments of later monasticism; while both tendencies, anti-worldliness and anti-sensualism, seem to have combined in causing the preference of celibacy over marriage which is common to most early Christian writers.[1] Patriotism, again, and the sense of civic duty, the most elevated and splendid of all social sentiments in the general view of Græco-Roman civilization, tended, under the influence of Christianity, either to expand itself into universal philanthropy, or to concentrate itself on the ecclesiastical community. "We recognize one commonwealth, the world," says Tertullian; "we know," says Origen, "that we have a fatherland founded by the word of God." We might further derive from the general spirit of Christian unworldliness that repudiation of the secular modes of conflict, even in a righteous cause, which substituted a passive patience and endurance for the old pagan virtue of courage, in which the active element was prominent. Here, however, we clearly trace the influence of Christ's express prohibition of violent resistance to violence, and his inculcation, by example and precept, of a love that was to conquer even natural resentment. An extreme result of this influence is shown in Tertullian's view, that no Christian could properly hold the office of a secular magistrate in which he would have to doom to death, chains, imprisonment; but even more sober writers, such as Ambrose, extend Christian passivity so far as to preclude self-defence even against a murderous assault. The common sense of Christendom gradually shook off these extravagances; but the reluctance to shed blood lingered long, and was hardly extinguished even by the growing horror of heresy. We have a curious relic of this in the later times of ecclesiastical persecution, when the heretic was doomed to the stake that he might be punished in some manner "short of bloodshed."[2]

It is, however, in the impulse given to practical beneficence in all its forms, by the exaltation of love as the root of all virtues, that the most important influence of Christianity on the particulars of civilized morality is to be found; although the exact amount of this influence is here somewhat difficult to ascertain, since it merely carries further a development distinctly traceable in the history of pagan morality considered by itself. This development clearly appears when we compare the different post-Socratic systems of ethics. In Plato's exposition of the different virtues there is no mention whatever of benevolence, although his writings show a keen sense of the importance of friendship as an element of philosophic life, especially of the intense personal affection naturally arising between master and disciple. Aristotle goes somewhat further in recognizing the moral value of friendship (φιλία); and though he considers that in its highest form it can only be realized by the fellowship of the wise and good, he yet extends the notion so as to include the domestic affections, and takes notice of the importance of mutual kindness in binding together all human societies. Still in his formal statement of the different virtues, positive beneficence is only discernible under the notion of "liberality;" in which form its excellence is hardly distinguished from that of graceful profusion in self-regarding expenditure. Cicero, on the other hand, in his well-known paraphrase of a Stoic treatise on external duties (officia), ranks the rendering of positive services to other men as a chief department of social duty; and the Stoics generally recognized the universal fellowship and natural mutual claims of human beings as such. Indeed, this recognition in later Stoicism is sometimes expressed with so much warmth of feeling as to be hardly distinguishable from Christian philanthropy. Nor was this regard for humanity merely a doctrine of the school. Partly through the influence of Stoic and other Greek philosophy, partly from the natural expansion of human sympathies, the legislation of the empire during the first three centuries shows a steady development in the direction of natural justice and humanity; and some similar progress may be traced in the general tone of moral opinion. Still the utmost point that this development reached fell considerably short of the standard of Christian charity. Without dwelling on the immense impetus given to the practice of social duty generally by the religion that made beneficence a form of divine service, and identified "piety" with "pity," we have to put down as definite changes introduced by Christianity into the current moral view—(1) the severe condemnation and final suppression of the practice of exposing infants; (2) effective abhorrence of the barbarism of gladiatorial combats; (3) immediate moral mitigation of slavery, and a strong encouragement of emancipation; (4) great extension of the eleemosynary provision made for the sick and the poor. As regards almsgiving, however—the importance of which has caused it to usurp, in modern languages, the general name of "charity"—it ought to be observed that Christianity merely universalized a duty which has always been inculcated and maintained in conspicuous fulness by Judaism, within the limits of the chosen people. The same may be said of the stricter regulation which Christianity enforced on the relations of the sexes; except so far as the prohibition of divorce is concerned, and the stress laid on "purity of heart" as contrasted with merely outward chastity. Even the peculiarly Christian virtue of humility, which presents so striking a contrast to the Greek "high-mindedness," was to some extent anticipated in the Rabbinic teaching. Its far greater prominence under the new dispensation may be partly referred to the express teaching and example of Christ; partly in so far as the virtue is manifested in the renunciation of external rank and dignity, or the glory of merely secular gifts and acquirements, it is one aspect of the unworldliness which we have already noticed; while the deeper humility that represses the claim of personal merit even in the saint belongs to the strict self-examination, the continual sense of imperfection, the utter reliance on strength not his own, which characterize the inner moral life of the Christian. Humility in this latter sense, "before God," is an essential condition of all truly Christian goodness.

Obedience, patience, benevolence, purity, humility, alienation from the "world" and the "flesh," are the chief novel or striking features which the Christian ideal of practice suggests, so far as it can be placed side by side with that commonly accepted in Græco-Roman society. But we have yet to notice the enlargement of the sphere of ethics due to its close connection with theology; for while this added religious force and sanction to ordinary moral obligations, it equally tended to impart a moral aspect to religious belief and worship. "Duty to God"—as distinct from duty to man—had not been altogether unrecognized by pagan moralists, though the rather dubious relations of even the more orthodox philosophy to the established polytheism had generally prevented them from laying much stress upon it. But in the views of many Christians, religious worship and contemplation as far surpassed all other modes of human existence as pure philosophic speculation did in the view of Plato, Aristotle, and the Neo-Platonists; indeed, the more learned of the Eastern monks spoke of themselves as withdrawing from the world to the "pursuit of wisdom" (φιλοσοφία). Again, just as the Stoics held wisdom to be indispensable to real rectitude of conduct, while at the same time they included under the notion of wisdom a grasp of physical as well as ethical truth; so the similar emphasis laid on inwardness in Christian ethics caused orthodoxy or correctness of religious belief to be regarded as essential to goodness, and heresy as the most fatal of vices, corrupting as it did the very springs of Christian life. To the philosophers, however, convinced as they were that the multitude must necessarily miss true well-being through their folly and ignorance, it could never occur to guard against these evils by any other method than that of providing philosophic instruction for the few; whereas the Christian clergy, whose function it was to offer truth and eternal life to all mankind, naturally regarded theological misbelief as insidious preventable contagion. Indeed, their sense of its deadliness was so keen that, when they were at length able to control the secular administration, they rapidly overcame their aversion to bloodshed, and initiated that long series of religious persecutions to which we find no parallel in the pre-Christian civilization of Europe. It was not that Christian writers did not feel the difficulty of attributing criminality to sincere ignorance or error. But the difficulty is not really peculiar to theology; and the theologians usually got over it (as some philosophers had surmounted a similar perplexity in the region of ethics proper) by supposing some latent or antecedent voluntary sin, of which the apparently involuntary heresy was the fearful fruit.

---

[1] *E.g.*, Justin Martyr, Origen, Tertullian, Cyprian.

[2] Citra sanguinis effusionem.

Lastly, we must observe that in proportion as the legal conception of morality as a code of which the violation deserves supernatural punishment predominated over the philosophic view of ethics as the method for attaining natural felicity, the question of man's freedom of will to obey the law necessarily became prominent. At the same time it cannot be broadly said that Christianity took a decisive side in the metaphysical controversy on free-will and necessity; since, just as in Greek philosophy the need of maintaining freedom as the ground of responsibility clashes with the conviction that no one deliberately chooses his own harm, so in Christian ethics it clashes with the attribution of all true human virtue to supernatural grace, as well as with the belief in divine foreknowledge. All we can say is that in the development of Christian thought the conflict of conceptions was far more profoundly felt, and far more serious efforts were made to evade or transcend it.

Development of opinion in early Christianity.

In the preceding account of Christian morality, it has been already indicated that the characteristics delineated did not all exhibit themselves simultaneously to the same extent, or with perfect uniformity throughout the church. Partly the changes in the external condition of Christianity, and the different degrees of civilization in the societies of which it was the dominant religion, partly the natural process of internal development, continually brought different features into prominence; while again, the important antagonisms of opinion that from time to time expressed themselves in sharp controversies within Christendom frequently involved ethical issues—even in the Eastern church until the great labor of a dogmatic construction began in the 4th century, and in the Western church always. Thus, for example, the anti-secular tendencies of the new creed, to which Tertullian (160–220) gave violent and rigid expression, were exaggerated in the Montanist heresy which he ultimately joined; on the other hand, Clemens of Alexandria, in opposition to the general tone of his age, maintained the value of pagan philosophy for the development of Christian faith into true knowledge (Gnosis), and the value of the natural development of man through marriage for the normal perfecting of the Christian life. So again, there is a marked difference between the writers before Augustine and those that succeeded him in all that concerns the internal conditions of Christian morality. By Justin and other apologists the need of redemption, faith, grace is indeed recognized, but the theological system depending on these notions is not sufficiently developed[1] to come into even apparent antagonism with the freedom of the will. Christianity is for the most part conceived as essentially a proclamation through the Divine Word, to immortal beings gifted with free choice, of the true code of conduct sanctioned by eternal rewards and punishments. This legalism contrasts strikingly with the efforts of pagan philosophy to exhibit virtue as its own reward; and the contrast is triumphantly pointed out by more than one early Christian writer. Lactantius (*circ.* 300 A.D.), for example, roundly declares that Plato and Aristotle, referring everything to this earthly life, "made virtue mere folly;" though himself maintaining, with pardonable inconsistency, that man's highest good did not consist in mere pleasure, but in the consciousness of the filial relation of the soul to God. It is plain, however, that on this external legalistic view of duty it was impossible to maintain a difference in kind between Christian and pagan morality; the philosopher's conformity to the rules of chastity and beneficence, so far as it went, was indistinguishable from the saint's. But when this inference was developed in the teaching of Pelagius, it was repudiated as heretical by the church, under the powerful leadership of Augustine (354–430); and the doctrine of man's incapacity to obey God's law by his unaided moral energy was pressed to a point at which it was difficult to reconcile it with the freedom of the will. Augustine is fully aware of the theoretical indispensability of maintaining Free-Will, from its logical connection with human responsibility and divine justice; but he considers that these latter points are sufficiently secured if actual freedom of choice between good and evil is allowed in the single case of our progenitor Adam.[2] For since the *natura seminalis* from which all men were to arise already existed in Adam, in his voluntary preference of self to God humanity chose evil once for all; for which ante-natal guilt all men are justly condemned to perpetual absolute sinfulness and consequent punishment, unless they are elected by God's unmerited grace to share the benefits of Christ's redemption. Without this grace it is impossible for man to obey the "first greatest commandment" of love to God; and, this unfulfilled, he is guilty of the whole law, and is only free to choose between degrees of sin; his apparent external virtues have no moral value, since inner rightness of intention is wanting. "All that is not of faith is of sin;" and faith and love are mutually involved and inseparable; faith springs from the divinely imparted germ of love, which in its turn is developed by faith to its full strength, while from both united springs hope, joyful yearning towards ultimate perfect fruition of the object of love. These three Augustine (after St. Paul) regards as the three essential elements of Christian virtue; along with these he recognizes the fourfold division of virtue into prudence, temperance, courage, and justice; which, however, he explains to be in their true natures only the same love to God in different aspects or exercises. The severe uncompromising mysticism of this view may be at once compared and contrasted with the philosophical severity of Stoicism. Love of God in the former holds the same absolute and unique position as the sole element of moral work in human action, which, as we have seen, was occupied by knowledge of Good in the latter; and we may carry the parallel further by observing that in neither case is this severity in the abstract estimate of goodness necessarily connected with extreme rigidity in practical precepts. Indeed, an important part of Augustine's work as a moralist lies in the reconciliation which he labored to effect between the anti-worldly spirit of Christianity and the necessities of secular civilization. For example, we find him arguing for the legitimacy of judicial punishments and military service against an over-literal interpretation of the Sermon on the Mount. And, more generally, by adopting and giving currency to the well-known distinction between evangelical "counsels" and "commands," he defended the life of marriage and temperate enjoyment of natural good against the attacks of the more extravagant advocates of celibacy and self-abnegation; although he fully admitted the superiority of the latter method of avoiding the contamination of sin.

Augustine.

Ambrose.

The attempt to Christianize the old Platonic list of virtues, which we have noticed in Augustine's system, was probably due to the influence of his master Ambrose; in whose treatise *De officiis ministrorum* we find for the first time an exposition of Christian duty systematized on a plan borrowed from a pre-Christian moralist. It is interesting to compare Ambrose's account of what subsequently came to be known as the "four cardinal virtues" with the corresponding delineations in Cicero's[3] *De Officiis* which has served the bishop as a model. Christian Wisdom, so far as speculative, is of course primarily theological; it has God, as the highest truth, for its chief object, and is therefore necessarily grounded on faith. Christian Fortitude is essentially firmness in withstanding the seductions of good and evil fortune, resoluteness in the conflict perpetually waged against wickedness without carnal weapons—though Ambrose with the Old Testament in his hand, will not quite relinquish the ordinary martial application of the virtue. "Temperantia" retains the meaning of "observance of due measure" in all conduct, which it had in Cicero's treatise; though its notion is partly modified by being blended with the newer virtue of humility; while in the exposition of Christian Justice the Stoic doctrine of the natural union of all human interests is elevated to the full height and intensity of evangelical philanthropy; the brethren are bidden to regard all things useful as the common property of all. Ambrose, we should observe, is thoroughly aware of the fundamental union of these different virtues in Christianity, though he does not, like Augustine, resolve them all into the one central affection of love of God.

---

[1] To show the crudity of the notion of redemption in early Christianity, it is sufficient to mention that many fathers represent Christ's ransom as having been paid to the devil; sometimes adding that by the concealment of Christ's divinity under the veil of humanity a certain deceit was (fairly) practised on the great deceiver.

[2] It is to be observed that Augustine does not himself understand by "freedom" the power of willing either good or evil, but the power of willing good. The highest freedom, in his view, excludes the possibility of willing evil.

[3] Cicero's works are unimportant in the history of ancient ethics, as their philosophical matter was entirely borrowed from Greek treatises now lost; but the influence exercised by them (especially by the *De Officiis*) over mediæval and even modern readers was very considerable.

Ecclesiastical morality in the "Dark Ages."

The combination which Augustine introduced between these four cardinal virtues and the triad of Christian graces, Faith, Hope, and Love, determined the ground-plan of the treatment of systematic ethics for subsequent ecclesiastical writers generally. In antithesis to this list of virtues, an enumeration of the chief deadly sins obtained currency. These were at first commonly reckoned as eight; but a preference for mystical numbers characteristic of mediæval theologians finally reduced the received list to seven. The statement of them is somewhat variously given by different writers,—Pride, Avarice, Anger, Gluttony, Unchastity, are found in all the lists; the remaining two (or three) are variously selected from among Envy, Vain-glory, and the rather singular sins Gloominess (Tristitia) and Languid Indifference (Acidia or Acedia, from Greek *ἀκηδία*). These latter notions show pretty plainly, what indeed might be inferred from a study of the list as a whole, that it especially represents the moral experience of the monastic life; which for some centuries was more and more unquestioningly regarded as in a peculiar sense "religious." It should be observed that the (also Augustinian) distinction between "deadly" and "venial" sins had a technical reference to the quasi-jural administration of ecclesiastical discipline; which grew gradually more organized as the spiritual power of the church established itself amid the ruins of the Western empire, and slowly developed into the theocracy that almost dominated Europe during the latter part of the Middle Ages. "Deadly" sins were those for which formal ecclesiastical penance was held to be necessary, in order to save the sinner from eternal damnation; for "venial" sins he might obtain forgiveness, through prayer, almsgiving, and the observance of the regular fasts. We find that "penitential books" for the use of the confessional, founded partly on traditional practice and partly on the express decrees of synods, come into general use in the 7th century. At first they are little more than mere inventories of sins, with their appropriate ecclesiastical punishments; gradually cases of conscience come to be discussed and decided, and the basis is laid for that system of casuistry which reached its full development in the 14th and 15th centuries. This elaboration of ecclesiastical jurisprudence, and indeed the general relation of the church to the ruder races with which it had to deal during this period, necessarily tended to encourage a somewhat external view of morality; but a powerful counterpoise to this tendency was continually maintained by the Augustinian doctrine, transmitted through Gregory the Great, Isidore of Seville, and other influential writers of the philosophically barren period that intervened between the destruction of the Western empire and the rise of Scholasticism.

Mediæval moral philosophy.

The great effort of the scholastics to philosophize in harmony with the Christian dogma attained its completest result in the teaching of Thomas Aquinas. But before giving a brief account of the ethical part of his system, it will be well just to notice the salient points in the long and active discussion that led up to it,—the dogmatic construction of Anselm, the bold questions and suggestive paradoxes of Abelard, the subtle distinctions of Petrus Lombardus, and the novel Aristotelian erudition of Albertus Magnus; nor must we overlook the Neo-Platonic mysticism of Johannes Scotus (Erigena), though separated in time and thought from the main course of scholasticism. In the pantheistic system of this earliest of the great mediæval thinkers (*circ.* 810–877), the chief philosophic element is supplied by the influence of Plotinus, transmitted through an unknown author of the 5th century, who assumed the name of Dionysius the Areopagite. Accordingly the ethical side of his doctrine has the same negative and ascetic character that we have observed in Neo-Platonism. God is the only real Being; evil is essentially unreal and incognizable, and the concrete world of individuals only real in so far as it partakes of the divine nature; the true aim of man's life is to return to perfect union with God out of the degraded material existence into which he has fallen. This doctrine found no immediate acceptance, and was certainly unorthodox enough to justify the condemnation which it subsequently received from Pope Honorius III.; but its influence, together with that of the Pseudo-Dionysius, had a considerable share in developing the more emotional orthodox mysticism of the 12th and 13th centuries; and Neo-Platonism remained a distinct element in mediæval thought, though obscured by the growing influence of Aristotle, until its revival in the age of the Renaissance. Passing on to Anselm (1033–1109), the first real scholastic of importance, we observe that the Augustinian doctrine of original sin and man's absolute need of unmerited grace is retained in his theory of salvation; he also follows Augustine in defining freedom as the "power not to sin;" though in saying that Adam fell "spontaneously" and "by his free choice," though not "through its freedom," he has implicitly made the distinction that Petrus Lombardus afterwards expressly draws between the freedom that is opposed to necessity and freedom from the slavery to sin. Anselm further softens the statement of Augustinian predestinationism by explaining that the freedom to will is not strictly lost even by fallen man; it is inherent in a rational nature, though since Adam's sin it only exists potentially in humanity,—like the faculty of sight in a dark place,—except where it is made actual by grace. In a more real sense Abelard (1079–1142) tries to establish the connection between man's ill desert and his free consent; boldly asserting that the inherited propensity to evil is not strictly a sin, which is only committed when the conscious self yields to vicious inclination. With a similar stress on the self-conscious side of moral action, he argues that rightness of conduct depends solely on the intention; at one time pushing this doctrine to the paradoxal assertion that all outward acts as such are indifferent.[1] In the same spirit under the reviving influence of ancient philosophy (though as yet imperfectly known), he argues that the old Greek moralists, as inculcating a disinterested love of good—and so implicitly love of God as the highest good—were really nearer to Christianity than Judaic legalism was. Nay, further, in the Christian "love to God" he distinguishes the disinterested love of God for Himself from the affection of which the real object is the happiness which God gives, and regards the former alone as pure. The general tendency of Abelard's thought was suspiciously regarded by contemporary orthodoxy;[2] and the over-subtlety of the last-mentioned distinction provoked vehement replies from more than one of the orthodox mystics of the age. Thus, Hugo of St. Victor (1077–1141) argues that all love is necessarily so far "interested" that it involves a desire for union with the beloved; and since eternal happiness consists in this union, it cannot truly be desired apart from God; while Bernard of Clairvaux (1091–1153) more elaborately distinguishes four stages by which the soul is gradually led from (1) merely self-regarding desire for God's aid in distress, to (2) love Him for His loving-kindness to it, then also (3) for His absolute goodness, until (4) in rare moments this love for Himself alone becomes the sole all-absorbing affection. This controversy, as well as others, Petrus Lombardus endeavored to compose by the scholastic art of taking distinctions, of which he was a master. His famous treatise, *Libri Sententiarum*, though not systematic or profound, deserved the place it long held as a text-book of Catholic theology, by its combined comprehensiveness and minuteness of view, and its sobriety of judgment. It is mainly based on Augustinian doctrine, though we find in it a distinct softening of the traditional antithesis between nature and grace; somewhat anticipating the remarkable union of Aristotelian and Christian thought, which in the succeeding century, when the study of Aristotle had been revived by the influence of the great Arabian commentators, was initiated by Albert the Great and completed by Thomas Aquinas.

---

[1] Abelard afterwards retracted this view, at least in its extreme form; and in fact does not seem to have been fully conscious of the difference between (1) unfulfilled intention to do an act objectively right, and (2) intention to do what is merely believed by the agent to be right.

[2] He was condemned by two synods, in 1121 and 1140.

Thomas Aquinas.

The moral philosophy of Thomas Aquinas is Aristotelianism with a Neo-Platonic tinge, interpreted and supplemented by Christian dogma. All action or movement of all things irrational as well as rational is directed towards some end or good,—that is, really and ultimately towards God Himself, the ground and first cause of all being, and unmoved principle of all movement. This universal striving after God, since He is essentially intelligible, exhibits itself in its highest form in rational beings as a desire for knowledge of Him; such knowledge, however, is beyond all ordinary exercise of reason, and may only be partially revealed to man here below. Thus the *summum bonum* for man is objectively God, subjectively the happiness to be derived from loving vision of His perfections; although there is a lower kind of happiness to be realized here below in a normal human existence of virtue and friendship, with mind and body sound and whole and properly trained for the needs of life. The higher happiness is given to man by free grace of God; but it is only given to those whose heart is right, and as a reward of virtuous actions. Passing to consider what actions are virtuous, we first observe generally that the morality of an act is in part, but only in part, determined by its particular motive; it partly depends on its external object and circumstances, which render it either objectively in harmony with the "order of reason" or the reverse. In the classification of particular virtues and vices we can distinguish very clearly the elements supplied by the different teachings which Thomas has imbibed. In dividing the "natural" virtues into intellectual and moral, giving his preference to the former class, and distinguishing in it the "intellect" that is conversant with principles, the "science" which deduces conclusions, and the "wisdom" to which belongs the whole process of knowing the sublimest objects of knowledge, Thomas follows Aristotle closely; his distinction among moral virtues of the justice that renders others their due from the virtues that control the appetites and passions of the agent himself, represents his interpretation of the Nicomachean ethics; while his account of these latter virtues is a simple transcript of Aristotle's, just as his division of the non-rational element of the soul into "concupiscible" and "irascible" is the old Platonic one. In arranging his list, however, he defers to the established doctrine of the four cardinal virtues; accordingly, the Aristotelian ten have to stand under the higher genera of (1) the prudence which gives reasoned rules of conduct, (2) the temperance which restrains the passions, and (3) the fortitude that strengthens the soul against them. But before these virtues, which belong to the nature of man as a rational creature, and can be acquired, though not perfectly, as a mere natural result of training and practice, are ranked the three "theologic" virtues, faith, love, and hope, supernaturally "instilled" by God, and directly relating to Him as their object. By faith we obtain that part of our knowledge of God which is beyond the range of mere natural wisdom or philosophy; naturally (*e.g.*), we can know God's existence, but not His trinity in unity, though philosophy is useful to defend this and other revealed verities. Faith is the substantial basis of all Christian morality, but without love—the essential form of all the Christian virtues—it is "formless" (informis). Christian love is conceived (after Augustine) as primarily love to God (beyond the natural yearning of the creature after its ultimate good), which expands into love towards all God's creatures as created by Him, and so ultimately includes even self-love. But creatures are only to be loved in their purity as created by God; all that is bad in them must be an object of hatred till it is destroyed. In the classification of sins the Christian element predominates; still we find the Aristotelian vices of excess and defect, along with the modern divisions into "sins against God, neighbor, and self," "mortal and venial sins," etc.

When from the essentially jural notion of sin we pass to the discussion of law, we observe another element in Thomas's doctrine, drawn from a different part of the renascent intellectual activity of Europe,—from the study, namely, of Roman jurisprudence, which attained in the 12th century so rapid and brilliant a revival in Italy. This side of Thomas's system is specially important to notice, since it is just this blending of theological conceptions with the abstract theory of the later Roman law that gave the starting point for independent ethical thought in the modern world. Under the general idea of law, defined as an "ordinance of reason for the common good," promulgated by him who has charge of the community, Thomas distinguishes (1) the eternal law or regulative reason of God which embraces all his creatures, rational and irrational; (2) "natural law," being that part of the eternal law that relates to rational creatures as such; (3) human law, which properly consists of more particular deductions from natural law adapted to the circumstances of particular societies; (4) divine law specially revealed to man. As regards natural law, he teaches that God has firmly implanted in the human mind a knowledge of its immutable general principles, although the applications of them may sometimes be obscured and perverted by bad education and custom. Human law is required, not merely to determine the details for which natural law gives no clear guidance, but also to supply the force necessary for practically securing, among imperfect men, the observance of the most necessary rules of mutual behavior. A further force is supplied by the revealed code of the decalogue and the gospel combined, which again goes beyond natural law in directing the way to eternal life. We have, however, to distinguish in the case of the gospel between (1) absolute commands and (2) "counsels," which latter recommend, without positively ordering, the monastic life of poverty, celibacy, and obedience, as the best method of effectively turning the will from earthly to heavenly things. Finally, to express the manner in which the moral law operates in the mind, Thomas uses and defines the specially Christian notion of conscience, distinguishing the "synderesis"[1] (*συντηρήσις*) by which moral principles are permanently retained from the "conscientia" by which they are applied to particular cases.

But how far is man able to attain either natural or Christian perfection? This is the part of Thomas's system in which the cohesion of the different elements composing it seems weakest. He is scarcely aware that his Aristotelianized Christianity inevitably combines two different difficulties in dealing with this question; first, the old pagan difficulty of reconciling the position that will is a rational desire always directed towards apparent good with the freedom of choice between good and evil that the jural view of morality seems to require; and, secondly, the Christian difficulty of harmonizing this latter notion with the absolute dependence on divine grace which the religious consciousness affirms. The latter difficulty Thomas, like many of his predecessors, avoids by supposing a "co-operation" of free-will and grace, but the former he does not fully meet. It is against this part of his doctrines that the most important criticism, in ethics, of his rival Duns Scotus (1266–1308), was directed. He urged that will could not be really free if it were bound to reason, as Thomas (after Aristotle) conceives it; a really free choice must be perfectly indeterminate between reason and unreason. Scotus consistently maintained that the divine will is similarly independent of reason, and that the divine ordering of the world is to be conceived as absolutely arbitrary,—a point on which he was followed by the acute intellect of William of Occam (d. 1347). This doctrine is obviously hostile to all reasoned morality; and in fact, notwithstanding the dialectical ability of Scotus and Occam, the work of Thomas remained indubitably the crowning result of the great constructive effort of mediæval philosophy. The effort, was, indeed, foredoomed to failure, since it attempted the impossible task of framing a coherent system out of the heterogeneous data furnished by Scripture, the fathers, the church, and "the Philosopher"—equally unquestioned, if not equally venerated, authorities. Whatever philosophic quality is to be found in the work of Thomas belongs to it in spite of, not in consequence of, its method. Still, its influence has been great and long-enduring,—in the Catholic Church primarily, but indirectly among Protestants, especially in England, since the famous first book of Hooker's *Ecclesiastical Polity* is to a great extent taken from the *Summa Theologiæ*.

Partly in conscious antagonism to the erudite labors and dialectical conflicts of the schoolmen, yet with close affinity to the central ethico-theological doctrine which they read out of or into Aristotle, the mystical manner of thought continued to maintain itself in the church. Philosophically it leant upon Neo-Platonism, but always blending the

[1] The "synderesis" of the Catholic mystics is a different notion; it is the "apex mentis," the highest faculty of the mind, by which the most perfect communion with the Divine nature is realized.

Christian element of love with the ecstatic vision of Plotinus, and sometimes giving the former a decided predominance. In its more moderate form, keeping wholly within the limits of ecclesiastical orthodoxy, this mysticism is represented by Bonaventura and Gerson; while it appears more independent and daringly constructive in the German Eckhardt, advancing in some of his followers to open breach with the church, and even to practical immorality.

Casuistry and Jesuitry.

In the brief account above given of the general ethical view of Thomas Aquinas no mention has been made of the detailed discussion of particular duties included in the *Summa Theologiæ;* in which, for the most part, an excellent combination of moral elevation with sobriety of judgment is shown, though on certain points the scholastic pedantry of definition and distinction is unfavorable to due delicacy of treatment. As the properly philosophic interest of scholasticism faded in the 14th and 15th centuries, the quasi-legal treatment of morality came again into prominence, borrowing a good deal of matter from Thomas and other schoolmen. The best known *Summa Casuum Conscientiæ*, compiled for the conduct of auricular confession, belong to the 14th and 15th centuries. As the chief of these we may mention the *Astesana* (14th century) and the *Angelica* (15th century) by two Franciscans, Astesanus and Angelus de Clavasio respectively. It was inevitable that, in proportion as this casuistry assumed the character of a complete and systematic penal jurisprudence, its precise determination of the limits between the prohibited and the allowable, with all doubtful points closely scrutinized and illustrated by fictitious cases, would have a tendency to weaken the moral sensibilities of ordinary minds; while, again, the more industry and ingenuity were spent in deducing conclusions from the diverse authorities accepted in the church, the greater necessarily became the number of points on which doctors disagreed; and the central authority that might have repressed serious divergences was wanting in the period of moral weakness[1] that the church went through, between the death of Boniface VIII. and the counter-Reformation. A plain man perplexed by such disagreements might naturally hold that any opinion maintained by a pious and orthodox writer must be a tolerably safe one to follow; and thus weak consciences might be subtly tempted to seek the support of authority for some desired relaxation of a moral rule. It does not, however, appear that this danger assumed formidable proportions until after the Reformation; when, in the struggle made by the Catholic Church to recover its hold on the world, the principle of authority was, as it were, forced into keen competition with that of private judgment for the guidance of men's consciences. To the Jesuits, the foremost champions in this struggle, it seemed indispensable that the confessional should be made attractive; for this purpose ecclesiastico-moral law must be somehow "accommodated" to worldly needs; and the theory of "Probabilism" supplied a plausible method for effecting this accommodation. The theory proceeded thus:—A layman could not be expected to examine minutely into a point on which the learned differed; therefore he could not fairly be blamed for following any opinion that rested on the authority of even a single doctor; therefore his confessor must be authorized to hold him guiltless if any such "probable" opinion could be produced in his favor; nay, it was his duty to suggest such an opinion, even though opposed to his own, if it would relieve the conscience under his charge from a depressing burden. The results to which this Probabilism, applied with an earnest desire to avoid dangerous rigor, led in the 17th century were revealed to the world in the immortal *Lettres Provinciales* of Pascal.

The Reformation. Transition to modern ethical philosophy.

In tracing the development of casuistry we have been carried beyond the great crisis through which Western Christianity passed in the 16th century. The Reformation which Luther initiated may be viewed on several sides, even if we consider only its ethical principles and effects, apart from the political and social aims and tendencies with which it was connected in different European countries. It maintained the simplicity of Apostolic Christianity against the elaborate system of a corrupt hierarchy, the teaching of Scripture alone against the commentaries of the fathers and the traditions of the church, the right of private judgment against the dictation of ecclesiastical authority, the individual responsibility of every human soul before God in opposition to the papal control over purgatorial punishments, which had led to the revolting degradation of venal indulgences. Reviving the original antithesis between Christianity and Jewish legalism, it maintained the inwardness of faith to be the sole way to eternal life, in contrast to the outwardness of works; returning to Augustine, and expressing his spirit in a new formula, to resist the Neo-Pelagianism that had gradually developed itself within the apparent Augustinianism of the church, it maintained the total corruption of human nature, as contrasted with that "congruity" by which, according to the schoolmen, divine grace was to be earned: renewing the fervent humility of St. Paul, it enforced the universal and absolute imperativeness of all Christian duties, and the inevitable unworthiness of all Christian obedience, in opposition to the theory that "condign" merit might be gained by "supererogatory" conformity to evangelical "counsels." It will be seen that these changes, however profoundly important, were, ethically considered, either negative or quite general, relating to the tone and attitude of mind in which all duty should be done. As regards all positive matter of duty and virtue, and most of the prohibitive code for ordinary men the tradition of Christian teaching was carried on substantially unchanged in the discourses and writings of the Reformed churches. Even the old method of casuistry was maintained[2] during the 16th and 17th centuries; though scriptural texts, interpreted and supplemented by the light of natural reason, now furnished the sole principles on which cases of conscience were decided. But in the 17th century the interest of this quasi-legal treatment of morality gradually faded; and the ethical studies of educated minds were occupied with the attempt, renewed after so many centuries, to find an independent philosophical basis for the moral code. The renewal of this attempt was only indirectly due to the Reformation; it is rather to be connected with the more extreme reaction from the mediæval religion which was partly caused by, partly expressed in, that enthusiastic study of the remains of old pagan culture that spread from Italy over Europe in the 15th and 16th centuries. To this "humanism" the Reformation seemed at first more hostile than the Roman hierarchy; indeed, the extent to which this latter had allowed itself to become paganized by the Renaissance was one of the points that especially roused the Reformers' indignation. Not the less important is the indirect stimulus given by the Reformation towards the development of a moral philosophy independent alike of Catholic and Protestant assumptions. Scholasticism, while reviving philosophy as a handmaid to theology, had metamorphosed its method into one resembling that of its mistress; thus shackling the renascent intellectual activity which it stimulated and exercised by the double bondage to Aristotle and to the church. When the Reformation shook the traditional authority in one department, the blow was necessarily felt in the other. Not twenty years after Luther's defiance of the pope, the startling thesis "that all that Aristotle taught was false" was prosperously maintained by the youthful Ramus before the university of Paris; and almost contemporaneously the group of remarkable thinkers in Italy who heralded the dawn of modern physical science—Cardanus, Telesius, Patritius, Campanella, Bruno—began to propound their un-Aristotelian theories of the constitution of the physical universe. It was to be foreseen that a similar assertion of independence would make itself heard in ethics also; and, indeed, amid the clash of dogmatic convictions, the variations and aberrations of private judgment, that the multiplying divisions of Christendom exhibited after the Reformation, reflective persons would naturally be led to seek for an ethical method that might claim universal acceptance from all sects.

IV. MODERN, ESPECIALLY ENGLISH, ETHICS.—The need of such independent principles was most strongly felt in the region of man's civil and political relations, especially the mutual relations of communities. Accordingly we find

---

[1] The refusal of the council of Constance to condemn Jean Petit's advocacy of assassination is a striking example of this weakness. *Cf.* Milman, *Lat. Christ.*, book xiii. c. 9.

[2] As the chief English casuists we may mention Perkins, Hall, Sanderson, as well as the more eminent Jeremy Taylor, whose *Ductor Dubitantium* appeared 1660.

Grotius.

that modern ethical controversy was commenced in the form of a discussion of the law of nature, of which first Albericus Gentilis (1557–1611), then Hugo Grotius (1583–1645) in his epoch-making work on international law, endeavored to give a complete theoretical view. Natural law, according to Grotius, is that part of divine law which follows from the essential nature of man; it is therefore as unalterable even by God himself as the truths of mathematics, although it may be overruled in any particular case by express revelation; hence it is cognizable *a priori*, from the abstract consideration of human nature, though its existence may also be known *a posteriori* from its universal acceptance in human societies. The conception, as we have seen, was taken from the later Roman jurists; by them, however, the law of nature was hardly conceived as actually having a substantive existence independent of positive codes; it was rather something that underlay existing law, and was to be looked for through it, though it might perhaps be expected ultimately to supersede it, and in the mean while represented an ideal standard, by which improvements in legislation were to be guided. Hence they do not seem to have framed, except in poetical or mythical imagination, the notion of a state of nature in which human beings were governed by the law of nature alone. But as soon as the principles of this code were contemplated as determining international rights and duties, it was obvious that in the present mutual relations of independent nations, regarded as corporate units, we have an actual example of this state of nature. Thus it was an easy step to suppose definitely that in prehistoric times individuals or single families lived similarly side by side,—under none other than such "natural" laws as those prohibiting mutual injury, and mutual interference with each other's use of the goods of the earth that were common to all, giving parents authority over their children, imposing on wives a vow of fidelity to their husbands, and obliging all to the observance of compacts freely entered into. It was not, of course, assumed that these laws were universally obeyed; indeed, one point with which Grotius is especially concerned is the natural right of private war, arising out of the violation of more primary rights. Still a general observance was involved in the idea of a natural law as a "dictate of right reason indicating the agreement or disagreement of an act with man's rational and social nature;" and we may observe that it was especially necessary to assume such a general observance in the case of contracts; since it was by an "express or tacit pact" that the right of property (as distinct from the mere right to non-interference during use) was held to have been instituted; and only by a similar "fundamental pact" could men be thought to pass legitimately from the state of nature to that of an organized society.

The ideas above expressed were not peculiar to Grotius; in particular the doctrine of the "fundamental pact" as the jural basis of government had long been maintained, especially in England, where the constitution historically established readily suggested such a compact. At the same time the rapid and remarkable success of Grotius's treatise would bring his view of Natural Right into prominence, and would suggest to penetrating minds such questions as—"What is man's ultimate reason for obeying these laws? Wherein does this their agreement with his rational and social nature exactly consist? How far, and in what sense, is his nature really social?"

Hobbes.

It was the answer which Hobbes (1588–1679) gave to these fundamental questions that supplied the starting-point for independent ethical philosophy in England. The nature of this answer was determined by the psychological views to which Hobbes had been led, partly under the influence of Bacon,[1] partly perhaps through association with his younger contemporary Gassendi, who, in two treatises, published between the appearance of Hobbe's *De Cive* (1642) and that of the *Leviathan* (1651), endeavored to revive interest in the life and teaching of Epicurus. Hobbes's psychology is in the first place materialistic; he holds, that is, that in any of the psychophysical phenomena of human nature the reality is a material process of which the mental feeling is a mere "appearance." Accordingly he regards pleasure as essentially motion "helping vital action," and pain as motion "hindering" it. There is no logical connection between this theory and the doctrine that appetite or desire has always pleasure (or the absence of pain) for its object; still a materialist, framing a system of psychology, will naturally direct his attention to the impulses arising out of bodily wants, whose obvious end is the preservation of the material organism; and this, together with a philosophic wish to simplify, may lead him to the conclusion that all human impulses are similarly self-regarding. This, at any rate, is Hobbes's cardinal doctrine in moral psychology, that each man's appetites or desires are naturally directed either to the preservation of his life, or to that heightening of it which he feels as pleasure;[2] including the aversions that are similarly directed "fromward" pain. Hobbes does not distinguish instinctive from deliberate pleasure-seeking; and he confidently resolves the most apparently unselfish emotions into phases of self-regard. Pity he finds to be grief for the calamity of others, arising from imagination of the like calamity befalling one's self; what we admire with seeming disinterestedness as beautiful (*pulchrum*) is really "pleasure in promise;" when men are not immediately seeking present pleasure, they desire power as a means to future pleasure, and thus have a derivative delight in the exercise of power that prompts to what we call benevolent action. Since, then, all the voluntary actions of men tend to their own preservation or pleasure, it cannot be reasonable to aim at anything else; in fact, nature rather than reason fixes this as the end of human action, to which it is reason's function to show the means. Hence if we ask why it is reasonable for any individual to observe the rules of social behavior that are commonly called moral, the answer is obvious that this is only indirectly reasonable, as a means to his own preservation or pleasure. It is not, however, in this, which is only the old Cyrenaic or Epicurean answer, that the distinctive point of Hobbism lies; but rather in the doctrine that even this indirect reasonableness of the most fundamental moral rules is entirely conditional on their general observance, which cannot be secured without the intervention of government. *E.g.*, it is not reasonable for me to perform my share of a contract unless I have adequate reason for believing that the other party will perform his; and this adequate reason I cannot have, except in a state of society in which he will be punished for non-performance. Thus the ordinary rules of social behavior are only hypothetically obligatory in any society, until they are actualized by the establishment of a strong central authority. On the other hand, Hobbes yields to no one in maintaining the paramount importance of moral regulations. The precepts of good faith, equity, requital of benefits, forgiveness of wrong so far as security allows, the prohibition of contumely, pride, arrogance, and other subordinate rules, he still calls "immutable and eternal laws of nature,"—meaning that, though they do not unconditionally bind us to realize them, they always bind to a desire that they should be realized. The pre-social state of man, in his view, is also pre-moral; but it is therefore utterly miserable. It is a state in which every one has a right to everything that may conduce to his preservation;[3] but it is therefore also a state of war in which every man's hand is against his neighbor's,—a state so wretched and perilous that it is the first dictate of rational self-love to emerge from it into social peace and order. Hence Hobbes's ideal constitution naturally comes to be an unquestioned and unlimited—though not necessarily monarchical—despotism. Whatever the government declares to be just or unjust must be taken to be so, since to dispute its dictates would be the first step towards anarchy, the one paramount peril outweighing all particular defects in legislation and administration. It is perhaps easy to understand, how, in 1651, a peace-loving philosopher, weary of the din of warring sects, should regard the claims of individual conscience as essentially anarchical, and the most threatening danger to social well-being; but however strong might be men's yearning for order, a view of social duty, in which the only fixed positions were selfishness everywhere and unlimited power somewhere, could not appear offensively paradoxical.

---

[1] This influence was not exercised in the region of ethics. Bacon's brief outline of moral philosophy (in the *Advancement of Learning*) is highly pregnant and suggestive; but the outline was never filled in, and does not seem to have had any effect in determining the subsequent course of thought in England.

[2] He even identifies the desire with the pleasure, apparently regarding the stir of appetite and that of fruition as two parts of the same "motion."

[3] In spite of Hobbes's uncompromising egoism, there is a noticeable discrepancy between his theory of the ends that men naturally seek and his standard for determining their natural rights. This latter is never Pleasure simply, but always Preservation—though on occasion he enlarges the notion of "preservation" into "preservation of life so as not to be weary of it." His view seems to be that in a state of nature *most* men *will* fight, rob, etc., "for delectation merely" or "for glory," and that hence all men must be allowed an indefinite right to fight, rob, etc., "for preservation."

However, offensive or not, there was an originality, a force, an apparent coherence in Hobbism which rendered it undeniably impressive; in fact, we find that for two generations the efforts to construct morality on a philosophical basis take more or less the form of answers to Hobbes. From an ethical point of view Hobbism divides itself naturally into two parts, which are combined by Hobbes's peculiar political doctrines into a coherent whole, but are not otherwise necessarily connected. Its theoretical basis is the principle of egoism, that it is natural and so reasonable for each individual to aim solely at his own preservation or pleasure; while, for practically determining the particulars of duty, it makes morality entirely dependent on positive law and institution. It is this latter part or aspect of the system which is primarily attacked by the first generation of writers that replied to Hobbes. This attack, or rather the counter-exposition of orthodox doctrine, is conducted on different methods by the Cambridge moralists and by Cumberland respectively. The latter retains the legal view of morality, and endeavors, while showing the actuality of the laws of nature, to systematize them by reducing them to a single principle. The former, regarding morality primarily as a body of truth rather than a code of rules, insist on its absolute character and intuitive certainty.

The Cambridge moralists. Cudworth.

Cudworth was the most distinguished of the little group of thinkers at Cambridge in the 17th century, commonly known as the "Cambridge Platonists," who, embracing what they conceived to be Platonic principles, but also strongly influenced by the new thought of Descartes, endeavored to blend rational theology with religious philosophy. In his treatise on *Eternal and Immutable Morality* (which was not published till more than 40 years after his death in 1688), his main aim is to maintain the "essential and eternal distinctions of good and evil," as independent of mere will, whether human or divine. These distinctions, he insists, have an objective reality, cognizable by reason or intellect as much as any physical fact; and he endeavors to refute Hobbism—which he treats as a "novantique philosophy," a mere revival of the relativism of Protagoras—by the following *argumentum ad hominem.* He argues that Hobbes's atomic materialism involves the conception of an objective physical world, the object not of sense that varies from man to man, but of the intellect that is the same in all; there is therefore an inconsistency in refusing to admit a similar exercise of intellect in morals, an objective world of duty, which the mind by its normal activity clearly apprehends as such. Cudworth, in the work above mentioned, gives no systematic exposition of the ethical principles which he holds to be clearly apprehended. But we may supply this deficiency from the *Enchiridion Ethicum* of Henry More, another thinker of the same school. More gives a list of 23 "Noemata Moralia," the truth of which will, he says, be immediately manifest. Some of these are purely egoistic,—as (*e.g.*) that goods differ in quality as well as duration, and that the superior good is always to be preferred, and similarly the lesser evil; that absence of a given amount of good is preferable to the presence of equivalent evil; that future good or evil is to be regarded as much as present, if equally certain, and nearly as much if very probable. Objections, both general and special, might be urged by a Hobbist against these modes of formulating man's natural pursuit of self-interest; but the serious controversy between Hobbism and modern Platonism did not relate to such principles as these, but to others which demand from the individual a (real or apparent) sacrifice for his fellows. Such are the evangelical principle of "doing as you would be done by;" the principle of justice, or "giving every man his own, and letting him enjoy it without interference;" and especially what More states as the abstract formula of benevolence, that "if it be good that one man should be supplied with the means of living well and happily, it is mathematically certain that it is doubly good that two should be so supplied, and so on." If we ask what motive any individual has to conform to these social principles when they conflict with his natural desires, Cudworth gives no explicit reply, and the answer of More is hardly clear. On the one hand he maintains that these principles express an absolute good; which is to be called intellectual because its essence and truth are defined and apprehended by the intellect. We might infer from this that the intellect, so judging, is itself the proper and complete determinant of the will, and that man as a rational being, ought to aim at the realization of absolute good for its own sake. But this does not seem to be More's view. He explains that though absolute good is discerned by the intellect, the "sweetness and flavor" of it is apprehended, not by the intellect proper, by what he calls a "boniform faculty;" and it is in this sweetness and flavor that the motive to virtuous conduct lies; ethics is the "art of living well and happily," and true happiness lies in "the pleasure which the soul derives from the sense of virtue." In short, Platonism, in More's mind, has been so far modernized that it turns out as hedonistic as Hobbism; the difference between the two lies merely in the degree of refinement of the pleasure that is taken as ultimate end.

More.

Cumberland.

It is to be observed that though More lays down the abstract principle of regarding one's neighbor's good as much as one's own with the full breadth with which Christianity inculcates it, yet when he afterwards comes to discuss and classify virtues he is too much under the influence of Platonic-Aristotelian thought to give a distinct place to benevolence, except under the old form of liberality. In this respect his system presents a striking contrast to Cumberland's, whose treatise *De Legibus Naturæ* (1672), though written like More's in Latin, is yet in its ethical matter thoroughly modern. Cumberland is a thinker both original and comprehensive, who has furnished material to more than one better-known moralist; but his academic prolixity and discursiveness, his academic language, and a want of clearness of view in spite of an elaborate display of exact and complete demonstration, have doomed his work to oblivion. At any rate he is noteworthy as having been the first to lay down that "regard for the common good of all" is the supreme rule of morality or Law of Nature, to which all other rules and virtues are strictly subordinate. So far he may be fairly called the precursor of modern utilitarianism. It is, however, important to notice that in his "good" is included not merely happiness, but "perfection;" and he does not even define perfection so as to exclude from it the notion of moral perfection or virtue, and save his theory from an obvious logical circle. A notion so vague could not possibly be used for determining the subordinate rules of morality with any precision; but in fact Cumberland does not attempt this; his supreme principle is not designed to rectify, but merely to support and systematize, common morality. This principle, as was said, is conceived as strictly a law, and therefore referred to a lawgiver, God, and provided with a sanction in the effects of its observance or violation on the agent's happiness. That the divine will is expressed by the proposition "that all rationals should aim at the common good of all," Cumberland, "not being so fortunate as to possess innate ideas," tries to prove by a long inductive examination of the evidences of men's essential sociality exhibited in his physical and mental constitution. His account of the sanction, again, is sufficiently comprehensive, including both the internal and the external rewards of virtue and punishments of vice; and he, like later utilitarians, explains moral obligation to lie in the force exercised on the will by these sanctions; but as to the precise manner in which individual is implicated with universal good, and the operation of either or both in determining volition, his view seems either indistinct or inconsistent.

Locke.

The clearness which we seek in vain from Cumberland is found to the fullest extent in a more famous writer, whose *Essay on the Human Understanding* (1690) was already planned when Cumberland's treatise appeared. And yet Locke's ethical opinions have been widely misunderstood; since from a confusion between "innate ideas" and "intuitions," which has been common in recent ethical discussion, it has been supposed that the founder of English empiricism must necessarily have been hostile to "intuitional" ethics. The truth is that, while Locke agrees entirely with Hobbes as to the egoistic basis of rational conduct, and the interpretation of "good" and "evil" as "pleasure" and "pain," or that which is productive of pleasure and pain, he yet agrees entirely with

Hobbes's opponents in holding ethical rules to be actually obligatory independently of political society, and capable of being scientifically constructed on principles intuitively known. This morality he conceives as the law of God, carefully distinguishing it, not only from civil law, but from the law of opinion or reputation, the varying moral standard by which men actually distribute praise and blame: as being divine it is necessarily sanctioned by adequate rewards and punishments. He does not, indeed, speak of the scientific construction of this code as having been actually effected, but he affirms its possibility in language remarkably strong and decisive. "The idea," he says, "of a Supreme Being, infinite in power, goodness, and wisdom, whose workmanship we are, and upon whom we depend, and the idea of ourselves, as understanding rational beings being such as are clear in us, would, I suppose, if duly considered and pursued, afford such foundations of our duty and rules of action, as might place morality among the sciences capable of demonstration, wherein, I doubt not, but from self-evident propositions, by necessary consequences as incontestable as those in mathematics, the measures of right and wrong might be made out." As Locke cannot consistently mean by God's "goodness" anything but the disposition to give pleasure, it would seem that the supreme rule of his system, as of Cumberland's, must prescribe universal benevolence; though the only instances which he gives of intuitive moral truths are the purely formal propositions, "No government allows absolute liberty," and "Where there is no property there is no injustice."

Clarke.

We might give, as a fair illustration of Locke's general conception of ethics, a system which is frequently represented as diametrically opposed to Lockism; namely, that expounded in Clarke's Boyle lectures on the *Being and Attributes of God* (1704). It is true that Locke is not particularly concerned with the ethico-theological proposition which Clarke is most anxious to maintain,—that the fundamental rules of morality are independent of arbitrary will, whether divine or human. But in his general view of ethical principles as being, like mathematical principles, essentially truths of relation, Clarke is quite in accordance with Locke; while of the four fundamental rules that he expounds, Piety, Equity, Benevolence, and Sobriety (which includes self-preservation), the first is obtained, just as Locke suggests, by "comparing the idea" of man with the idea of an infinitely good and wise being on whom he depends; and the second and third are axioms self-evident on the consideration of the equality or similarity of human individuals as such. The second axiom of equity—that "whatever I judge reasonable or unreasonable for another to do for me, that, by the same, I declare reasonable or unreasonable that I in the like case should do for him," is merely a formal statement of the golden rule of the gospel.[1] We may observe that, in stating the principle of benevolence, "since the greater good is always most fit and reasonable to be done, every rational creature ought to do all the good it can to its fellow-creatures," Clarke avowedly follows Cumberland, from whom he quotes the further sentence that "universal love and benevolence is as plainly the most direct, certain, and effectual means to this good as the flowing of a point is to produce a line." The quotation may remind us that the analogy between ethics and mathematics ought to be traced further back than Locke; in fact, it results from the influence exercised by Cartesianism over English thought generally, in the latter half of the 17th century. It must be allowed that Clarke is misled by the analogy to use general ethical terms ("fitness," "agreement" of things, etc.), which overlook the essential distinction between what is and what ought to be; and even in one or two expressions to overleap this distinction extravagantly, as (*e.g.*) in saying that the man who "wilfully acts contrary to justice wills things to be what they are not and cannot be." What he really means is less paradoxically stated in the general proposition that "originally and in reality it is natural and (morally speaking) necessary that the will should be determined in every action by the reason of the thing and the right of the case, as it is natural and (absolutely speaking) necessary that the understanding should submit to a demonstrated truth." Here no doubt Clarke is opposed to Locke; and even goes beyond the Platonists in affirming the immediate absolute determination of will by reason. But though it is an essential point in Clarke's view that what is right is to be done as such, apart from any consideration of pleasure or pain, it is to be observed that he is not prepared to apply this doctrine in its unqualified form to such a creature as man, who feels as wells as reasons. At least when he comes to argue the preferability of virtue to vice in reference to actual human choice, he does not make more than the very moderate claim that "virtue deserves to be chosen for its own sake, and vice to be avoided, though a man was sure for his own particular neither to gain nor lose anything by the practice of either." He fully admits that the question is altered when vice is attended by pleasure and profit to the vicious man, virtue by loss and calamity; and even that it is "not truly reasonable that men by adhering to virtue should part with their lives, if thereby they deprived themselves of all possibility of receiving any advantage from their adherence."

The truth is that the impressive earnestness with which Clarke enforces the doctrine of rational morality only renders more manifest the difficulty of establishing ethics on an independent philosophical basis; so long at least as the psychological egoism of Hobbes is not definitely assailed and overthrown. Until this is done, the utmost demonstration of the abstract reasonableness of social duty only leaves us with an irreconcilable antagonism between the view of abstract reason and the self-love which is allowed to be the root of man's appetitive nature. Let us grant that there is as much intellectual absurdity in acting unjustly as in denying that two and two make four; still, if a man has to choose between absurdity and unhappiness, he will naturally prefer the former; and Clarke cannot maintain that such preference is irrational?[2]

Shaftesbury.

It remains to adopt another line of reasoning; instead of presenting the principle of social duty as abstract reason, liable to conflict to any extent with natural self-love, we may try to exhibit the naturalness of man's social affections, and demonstrate a normal harmony between these and his self-regarding impulses. This is the line of thought which Shaftesbury (1671–1713) may be said to have initiated. Not, of course, that he is original in insisting on the actual fact of natural affections binding men to their fellows; Cumberland, to say nothing of earlier writers, had dwelt on this at some length. But no moralist before Shaftesbury had made this the cardinal point in his system; no one had undertaken to distinguish clearly, by careful analysis of experience, the disinterested and self-regarding elements of our appetitive nature, or to prove inductively their perfect harmony. He begins by attacking the egoistic interpretation of good which Hobbes had put forward, and which, as we have seen, was not necessarily excluded by the doctrine of moral intuitions. This interpretation, he says, would be only true if we considered man as a wholly unrelated individual. Such a being we might doubtless call "good," if his impulses and dispositions were harmonized and adapted to the attainment of his own felicity. But man we must and do consider in relation to a larger system of which he forms a part, and so we only call him "good" when his impulses and dispositions are so graduated and balanced as to tend towards the good of this whole. And observe, he adds, we do not attribute goodness to him merely because his outward acts have this tendency; the worst of men may be chained from harm, and lashed into usefulness by the fear of punishment. When we speak of a man as "morally" good, we mean that his dispositions or affections are such as tend of themselves to promote the good or happiness of human society. Hobbes's moral man, who, if let loose from governmental constraint, would straightway spread ruin among his fellows, is not what we commonly agree to call such. Moral goodness, then, involves disinterested affections, whose direct object is the good of others; but Shaftesbury does not mean (as he has been misunderstood to mean) that only such benevolent social impulses are good, and that these are always good. On the contrary, he is careful to point out, first, that immoderate social affections defeat themselves, miss their proper end, and are therefore bad; secondly, that as an individual's good is part of the good of the whole, "self-affections" existing in a duly limited degree are morally good. The moral ideal, in short, consists in due combination of both sorts of "affections," tendency to promote general good being taken as the criterion of the right mixture or balance. This being established, the main aim of Shaftesbury's argument is to prove that the same balance and blending of private and social affections, which tends naturally to public good, is also conducive to the happiness of the individual in whom it exists. Taking the different impulses in detail, he first shows how the individual's happiness is promoted by developing and exercising his social affections, mental pleasures being superior to bodily, and the pleasures of benevolence the richest of all. In discussing this he distinguishes, with well-applied subtlety, between the pleasurableness of the benevolent emotions themselves, the sympathetic enjoyment of the happiness of others, and the pleasure arising from a consciousness of their love and esteem. He then exhibits the unhappiness that results from any excess of the self-regarding impulses, bodily appetite, desire of wealth, emulation, resentment, even love of life itself; and ends by dwelling on the intrinsic painfulness of all malevolence.

---

[1] Even Hobbes accepts the golden rule in its negative application ("Do *not* unto others," etc.) as summarizing his "law of nature."

[2] It should be observed that, while Clarke is sincerely anxious to prove that most principles are binding independently of Divine appointment, he is no less concerned to show that morality requires the practical support of revealed religion.

One more special impulse remains to be noticed. We have seen that goodness of character consists in a certain balance and harmony of self-regarding and social affections. But virtue, in Shaftesbury's view, is something more; it implies a recognition of moral goodness and immediate preference of it for its own sake. This immediate pleasure that we take in goodness (and displeasure in its opposite) is due to a susceptibility which he calls the "reflex" or "moral" sense, and compares with our susceptibility to beauty and deformity in external things; it furnishes both an additional direct impulse to good conduct, and an additional gratification to be taken into account in the reckoning which proves the coincidence of virtue and happiness. This doctrine of the moral sense is sometimes represented as Shaftesbury's cardinal tenet; but though characteristic and important, it is not really necessary to his main argument; it is the crown rather than the keystone of his ethical structure.

Mandeville.

The appearance of Shaftesbury's *Characteristics* (1713) marks a turning-point in the history of English ethical thought. With the generation of moralists that followed the consideration of abstract rational principles falls into the background, and its place is taken by introspective study of the human mind, observation of the play of the various impulses and sentiments. This empirical psychology had not indeed been neglected by previous writers. More, among others, had imitated Descartes in a discussion of the passions, and Locke's essay had given a still stronger impulse in the same direction; still, Shaftesbury is the first moralist who distinctly takes psychological experience as the basis of ethics. His suggestions were developed by Hutcheson into one of the most elaborate systems of moral philosophy which we possess; through Hutcheson, if not directly, they influenced Hume's speculations, and are thus connected with later utilitarianism; while again, the substance of Shaftesbury's main argument was adopted by Butler, though it could not pass the scrutiny of that powerful and cautious intellect without receiving important modifications and additions. On the other hand, the ethical optimism of Shaftesbury, connected as it was with a natural theology that implied the Christian scheme to be superfluous, challenged attack equally from orthodox divines and from infidel pessimists. Of these latter, Mandeville, the author of *The Fable of the Bees, or Private Vices Public Benefits* (1724), was a conspicuous if not a typical specimen. He can hardly be called a "moralist;" and though it is impossible to deny him a considerable share of philosophical penetration, his anti-moral paradoxes have not even apparent coherence. He is convinced that virtue (where it is more than a mere pretence) is purely artificial; but not quite certain whether it is a useless trammel of appetites and passions that are advantageous to society, or a device creditable to the politicians who introduced it by playing upon the "pride and vanity" of the "silly creature man." The view, however, to which he gave eccentric expression, that moral regulation is something alien to the natural man, and imposed on him from without, seems to have been very current in the polite society of his time, as we learn both from Berkeley's *Alciphron* and from Butler's more famous sermons.

Butler.

The view of "human nature" against which Butler preached was not exactly Mandeville's, nor was it properly to be called Hobbist, although Butler fairly treats it as having a philosophical basis in Hobbes's psychology. It was, so to say, Hobbism turned inside out—rendered licentious and anarchical instead of constructive. Hobbes had said "the natural state of man is non-moral, unregulated; moral rules are means to the end of peace, which is a means to the end of self-preservation." On this view morality, so far as Hobbes deals with it, though conventional and dependent for its actuality on the social compact which establishes government, is actually binding on man as a reasonable being. But the quasi-theistic assumption that what is natural must be reasonable remained in the minds of Hobbes's most docile readers; and in combination with his new thesis that unrestrained egoism is natural, tended to produce results which, though not perhaps practically subversive of peace, were at any rate dangerous to social well-being. To meet this view Butler does not content himself, as he is sometimes carelessly supposed to do, with simply insisting on the natural claim to authority of the conscience which his opponent repudiated as artificial; he also uses a more subtle and effective argument *ad hominem*. He first follows Shaftesbury in exhibiting the social affections as no less natural than the appetites and desires which tend more directly to self-preservation; then going further and reviving the Stoic view of the *prima naturæ*, the first objects of natural appetites, he argues that pleasure is not the primary aim even of the impulses which Shaftesbury allowed to be "self-affections;" but rather a result which follows upon their attaining their natural ends. Thus the object (*e.g.*) of hunger is not the pleasure of eating, but food; hunger is, therefore, strictly speaking, no more "interested" than benevolence; granting that the pleasures of the table are an important element in the happiness at which self-love aims, the same may certainly be said for the pleasures of love and sympathy. Further, so far from bodily appetites (or other particular desires) being forms of self-love, there is no one of them which under certain circumstances, may not come into conflict with it. Indeed, it is common enough for men to sacrifice to passion what they know to be their true interests; at the same time we do not consider such conduct "natural" in man as a rational being; we rather regard it as natural for him to govern his transient impulses. Thus the notion of natural unregulated egoism turns out to be a psychological chimæra; for (1) man's primary impulses cannot be sweepingly called egoistic in any sense, since the objects of all are other than his own happiness, and the tendencies of some are as obviously social in the first instance as those of others are self-regarding; and (2) a man cannot be consistently egoistic without being continually self-regulative. Indeed, we may say, that an egoist must be doubly self-regulative, since rational self-love ought to restrain not only other impulses, but itself also; for as happiness is made up of feelings that result from the satisfaction of impulses other than self-love, any over-development of the latter, enfeebling these other impulses, must proportionally diminish the happiness at which self-love aims. If, then, it be admitted that human impulses are naturally under government, the natural claim of conscience or the moral faculty to be the supreme governor will be hardly denied.

But has not self-love also, by Butler's own account, a similar authority, which may come into conflict with that of conscience? Butler fully admits this, and, in fact, grounds on it an important criticism of Shaftesbury. We have seen that in the latter's system the "moral sense" is not absolutely required, or at least is only necessary as a substitute for enlightened self-regard; since if the harmony between prudence and virtue, self-regarding and social impulses, is complete, mere self-interest will prompt a duly enlightened mind to maintain precisely that "balance" of affections in which goodness consists. But to Butler's more cautious mind the completeness of this harmony did not seem sufficiently demonstrable to be taken as a basis of moral teaching; he has at least to contemplate the possibility of a man being convinced of the opposite; and he argues that unless we regard conscience as essentially authoritative—which is not implied in the term "moral sense"—such a man is really bound to be vicious; "since interest, one's own happiness, is a manifest obligation." Still on this view, even if the authority of conscience be asserted, we seem reduced to an ultimate dualism of our rational nature. Butler's ordered polity of impulses turns out to be a polity with two independent governments. Butler does not deny this, so far as mere claim to authority is concerned;[1] but he maintains that, the dictates of conscience being clear and certain, while the calculations of self-interest lead to merely probable conclusions, it can never be practically reasonable to disobey the former, even apart from any proof which religion may furnish of the absolute coincidence of the two in a future life.

---

[1] In a remarkable passage near the close of his eleventh sermon,

Wollaston.

This dualism of governing principles in Butler's system, and perhaps, too, his revival of the Platonic conception of human nature as an ordered and governed community of impulses, may be partly attributed to the influence of Wollaston's *Religion of Nature Delineated* (1722). Here, for the first time, we find "moral good" and "natural good" or "happiness" treated separately as two essentially distinct objects of rational pursuit and investigation; the harmony between them being regarded as matter of religious faith, not moral knowledge. Wollaston's theory of moral evil as consisting in the practical contradiction of a true proposition, closely resembles the most paradoxical part of Clarke's doctrine, and was not likely to approve itself to the strong common sense of Butler; but his statement of happiness or pleasure as a "justly desirable" end at which every rational being "ought" to aim corresponds exactly to Butler's conception of self-love as a naturally governing impulse; while the "moral arithmetic" with which he compares pleasures and pains, and endeavors to make the notion of happiness quantitatively precise, is an anticipation of Benthamism.

Hutcheson.

There is another side of Shaftesbury's harmony which Butler was ultimately led to oppose in a more decided manner,—the opposition, namely, between conscience or the moral sense and the social affections. In the *Sermons*, indeed (1729), Butler seems to treat conscience and calm benevolence as permanently allied though distinct principles, but in the *Dissertation on Virtue*, appended to the *Analogy* (1739), he maintains that the conduct dictated by conscience will often differ widely from that to which mere regard for the production of happiness would prompt. We may take this latter treatise as representing the first in the development of English ethics, at which what were afterwards called "utilitarian" and "intuitional" morality were first formally opposed; in earlier systems the antithesis is quite latent, as we have incidentally noticed in the case of Cumberland and Clarke.[1] The argument in Butler's dissertation was probably directed against Hutcheson, who in his "inquiry concerning the original of our ideas of virtue" had definitely identified virtue with benevolence. The identification is slightly qualified in Hutcheson's posthumously published *System of Moral Philosophy* (1755); in which the general view of Shaftesbury is more fully developed, with several new psychological distinctions, including Butler's separation of "calm" self-love and benevolence from the "turbulent" passions, selfish or social. Hutcheson also follows Butler in laying stress on the "governing" character of the moral sense; but he still regards "kind affections" as the principal objects of moral approbation—the "calm" and "extensive" affections being preferred to the turbulent and narrow —together with the desire and love of moral excellence which is ranked with universal benevolence, the two being equally worthy and necessarily harmonious. Only in a secondary sense is approval due to certain "abilities and dispositions immediately connected with virtuous affections," as candor, veracity, fortitude, sense of honor; while in a lower grade still are placed sciences and arts, along with even bodily skills and gifts; indeed, the approbation we give to these is not strictly moral, but is referred to the "sense of decency or dignity," which (as well as the sense of honor) is to be distinguished from the moral sense. Calm self-love Hutcheson regards as morally indifferent; though he enters into a careful analysis of the elements of happiness,[2] in order to show that a true regard for private interest always coincides with the moral sense and with benevolence. While thus maintaining Shaftesbury's "harmony" between public and private good, Hutcheson is still more careful to establish the strict disinterestedness of benevolent affections. Shaftesbury had conclusively shown that these were not in the vulgar sense selfish; but the very stress which he lays on the pleasure inseparable from their exercise suggests a subtle egoistic theory which he does not expressly exclude, since it may be said that this "intrinsic reward" constitutes the real motive of the benevolent man. To this Hutcheson replies that no doubt the exquisite delight of the emotion of love is a motive to sustain and develop it; but this pleasure cannot be directly obtained, any more than other pleasures, by merely desiring it; it can only be got indirectly by cultivating the affection, which is thus obviously distinct from the desire for benevolent pleasure, being (as is ordinarily supposed) an immediate desire for others' good. He points to the fact that the imminence of death often intensifies instead of diminishing a man's desire for the welfare of those he loves, as a crucial experiment proving the disinterestedness of love; adding, as confirmatory evidence, that the sympathy and admiration commonly felt for self-sacrifice depends on the belief that it is something different from refined self-seeking.

It remains to consider how, from the doctrine that affection is the proper object of approbation, we are to deduce moral rules or "natural laws" prescribing or prohibiting outward acts. It is obvious that all actions conducive to the general good will deserve our highest approbation if done from disinterested benevolence; but how if they are not so done? In answering this question, Hutcheson avails himself of the scholastic distinction between "material" and "formal" goodness. "An action," he says, "is *materially* good when in fact it tends to the interest of the system, so far as we can judge of its tendency, or to the good of some part consistent with that of the system, whatever were the affections of the agent. An action is *formally* good when it flowed from good affection in a just proportion." On the pivot of this distinction Hutcheson turns round from the point of view of Shaftesbury to that of later utilitarianism. His treatment of external rights and duties, though decidedly inferior in methodical clearness and precision, does not differ in principle from that of Paley or Bentham, except that he lays greater stress on the immediate conduciveness of actions to the happiness of individuals, and more often refers in a merely supplementary or restrictive way to their tendencies in respect of general happiness. It may be noticed, too, that he still accepts the "social compact" as the natural mode of constituting government, and regards the obligations of subjects to civil obedience as normally dependent on a tacit contract; though he is careful to state that consent is not absolutely necessary to the just establishment of beneficent government, nor the source of irrevocable obligation to a pernicious one.

Hume.

An important step further in political utilitarianism was taken by Hume in his *Treatise on Human Nature* (1739). Hume concedes that a compact is the natural means of peacefully instituting a new government, and may therefore be properly regarded as the ground of allegiance to it at the outset; but he urges that, when once it is firmly established, the duty of obeying it rests on precisely the same combination of private and general interests as the duty of keeping promises; it is therefore absurd to base the former on the latter. Justice, veracity, fidelity to compacts and to governments, are all co-ordinate; they are all "artificial" virtues, due to civilization, and not belonging to man in his "ruder and more natural" condition; our approbation of all alike is founded on our perception of their useful consequences. It is this last position that constitutes the fundamental difference between Hutcheson's ethical doctrine and Hume's.[3] The former, while accepting utility as the criterion of "material goodness," had adhered to Shaftesbury's view that dispositions, not results of action, were the proper object of moral approval; at the same time, while giving to benevolence the first place in his account of personal merit, he had shrunk from the paradox of treating it as the sole virtue, and had added a rather undefined and unexplained train of qualities,—veracity, fortitude, activity, industry, sagacity,—immediately approved in various degrees by the "moral sense" or the "sense of dignity." This naturally suggested to a mind like Hume's, anxious to apply the experimental method to psychology, the problem of reducing these different elements of personal merit—or rather our approval of them—to some

---

Butler seems even to allow that conscience would have to give way to self-love, if it were possible (which it is not) that the two should come into ultimate and irreconcilable conflict.

[1] *Cf. ante*, pp. 526–7.

[2] It is worth noticing that Hutcheson's express definition of the object of self-love includes "perfection" as well as "happiness;" but in the working out of his system he considers private good exclusively as happiness or pleasure.

[3] Hume's ethical view was finally stated in his *Inquiry into the Principles of Morals* (1751), which is at once more popular and more purely utilitarian than his earlier work.

common principle. The old theory that referred this approval entirely to self-love is, he holds, easy to disprove by "crucial experiments" on the play of our moral sentiments; rejecting this, he finds the required explanation in the sympathetic pleasure that attends our perception of the conduciveness of virtue to the interests of human beings other than ourselves. He endeavors to establish this inductively by a survey of the qualities commonly praised as virtues, which he finds to be always either useful or immediately agreeable, either (1) to the virtuous agent himself or (2) to others. In class (2) he includes, besides the Benevolence of Shaftesbury and Hutcheson, the useful virtues, Justice, Veracity, and Fidelity to compacts; as well as such immediately agreeable qualities as politeness, wit, modesty, and even cleanliness. The most original part of his discussion, however, is concerned with qualities immediately useful to their possessor. The most cynical man of the world, he says, with whatever "sullen incredulity" he may repudiate virtue as a hollow pretence, cannot really refuse his approbation to "discretion, caution, enterprise, industry, frugality, economy, good sense, prudence, discernment;" nor again, to "temperance, sobriety, patience, perseverance, considerateness, secrecy, order, insinuation, address, presence of mind, quickness of conception, facility of expression." It is evident that the merit of these qualities in our eyes is chiefly due to our perception of their tendency to serve the person possessed of them; so that the cynic in praising them is really exhibiting the unselfish sympathy of which he doubts the existence. Hume admits the difficulty that arises, especially in the case of the "artificial" virtues, such as justice, etc., from the undeniable fact that we praise them and blame their opposites without consciously reflecting on useful or pernicious consequences; but considers that this may be explained as an effect of "education and acquired habits." [1]

So far the moral faculty has been considered as contemplative rather than active; and this, indeed, is the point of view from which Hume mainly regards it. If we ask what actual motive we have for virtuous conduct, Hume's answer is not quite clear. On the one hand, he speaks of moral approbation as derived from "humanity and benevolence," while expressly recognizing, after Butler, that there is a strictly disinterested element in our benevolent impulses (as also in hunger, thirst, love of fame, and other passions). On the other hand, he does not seem to think that moral sentiment or "taste" can "become a motive to action," except as it "gives pleasure or pain, and thereby constitutes happiness or misery." It is difficult to make these views quite consistent; but at any rate Hume emphatically maintains that "*reason* is no motive to action," except so far as it "directs the impulse received from appetite or inclination;" and recognizes—in his later treatise at least—no "obligation" to virtue, except that of the agent's interest or happiness.

But even if we consider the moral consciousness merely as a particular kind of pleasurable emotion, there is an obvious question suggested by Hume's theory, to which he gives no adequate answer. If the essence of "moral taste" is sympathy with the pleasure of others, connected by transference with the qualities that tend to cause such pleasure, why is not this specific feeling excited by other things besides virtue? On this point Hume contents himself with the vague remark that "there are a numerous set of passions and sentiments, of which thinking rational beings are by the original constitution of nature the only proper objects." The truth is, that Hume's notion of moral approbation was very loose, as is sufficiently shown by the list of "useful and agreeable" qualities which he considers worthy of approbation.[2] It is therefore hardly surprising that his theory should leave the specific quality of the moral sentiments a fact still needing to be explained. An original and ingenious solution of this problem was offered by his contemporary Adam Smith, in his *Theory of Moral Sentiments* (1759). Adam Smith does not deny the actuality or importance of that sympathetic pleasure in the perceived or inferred effects of virtues and vices on which Hume laid stress. He does not, however, think that the essential part of common moral sentiment is constituted by this, but rather by a more direct sympathy with the impulses that prompt to action or expression. The spontaneous play of this sympathy he treats as an original and inexplicable fact of human nature, but he considers that its action is powerfully sustained by the pleasure that each man finds in the accord of his feeling with another's. By means of this primary element, compounded in various ways, Adam Smith explains all the different phenomena of the moral consciousness. He takes first the semi-moral notion of "propriety" or "decorum," and endeavors to show inductively that our application of this notion to the social behavior of another is determined by our degree of sympathy with the feeling expressed in such behavior. "To approve of the passions of another as suitable to their objects is the same thing as to sympathize with them." Similarly we disapprove of passion exhibited in a degree to which our sympathy cannot reach; and even, too, when it falls short; since, as he acutely points out, we often sympathize with the merely imagined feelings of others, and are thus disappointed when we find the reality absent. Thus the prescriptions of good taste in the expression of feeling may be summed up in the principle, "reduce or raise the expression to that with which spectators will sympathize." When the effort to restrain feeling is exhibited in a degree which surprises as well as pleases, it excites admiration as a virtue or excellence; such excellences Adam Smith quaintly calls the "awful and respectable," contrasting them with the "amiable virtues" which consist in the opposite effort to sympathize, when exhibited in a remarkable degree. From the sentiments of propriety and admiration we proceed to the sense of merit and demerit. Here a more complex phenomenon presents itself for analysis; we have to distinguish in the sense of merit—(1) a direct sympathy with the sentiments of the agent, and (2) an indirect sympathy with the gratitude of those who receive the benefit of his actions. In the case of demerit a direct antipathy to the feelings of the misdoer takes the place of sympathy; but the chief part of the sentiment excited is sympathy with those injured by the misdeed. The object of this sympathetic resentment, impelling us to punish, is what we call injustice; and thus the remarkable stringency of the obligation to act justly is explained, since the recognition of any action as unjust involves the admission that it may be forcibly obstructed or punished. To the obvious objection that we often approve and disapprove without sympathizing, it is replied that in such cases we correct or supplement present feelings by the general rules derived from preceding experience of our ordinary sentiments. Similarly the received maxims to which we commonly appeal as recognized standards of judgment are formed by the concurrent and mutually confirmed sympathies of mankind generally. Moral judgments, then, are expressions of the complex normal sympathy of an impartial spectator with the active impulses that prompt to and result from actions. When, however, such judgments are passed on our own conduct, a further complication of the fundamental element is required to explain them. What we call our conscience is really sympathy with the feelings of an imaginary impartial spectator looking at our conduct. Such a spectator, it is true, would not have full means for forming a judgment, but these we can supply in imagination; thus, "praiseworthy" (as distinguished from actually praised) conduct may be defined as "that with which an impartial and fully informed spectator would sympathize."

Adam Smith.

That the general rules of morality impressed on us by this complicated play of sympathy are "justly to be regarded as the laws of the Deity," Adam Smith takes care to assure us; but it can hardly be said that his theory affords any cogent arguments for this conclusion, or in any way establishes these rules as objectively valid. In the same way Hume insists emphatically on the "reality of moral obligation;" but is found to mean no more by this than the real existence of the likes and dislikes that human beings feel for each other's qualities. The fact was, that amid the observations and analysis of feelings to which the moral sentimentalism of Shaftesbury's school had led, the fundamental ethical questions "What is right" and "Why?" had been allowed to drop into the background, and the consequent danger to morality was manifest. The binding force of moral rules becomes evanescent if we admit, with

---

[1] Hume remarks that in some cases, by "association of ideas," the rule by which we praise and blame is extended beyond the principle of utility from which it arises; but he allows much less scope to this explanation in his second treatise than in his first.

[2] In earlier editions of the *Inquiry* Hume expressly included all approved qualities under the general notion of "virtue." In later editions he avoided this strain on usage by substituting or adding "merit" in several passages,—allowing that some of the laudable qualities which he mentions would be more commonly called "talents," but still maintaining that "there is little distinction made in our internal estimation" of "virtues" and "talents."

Hutcheson, that the "sense" of them may properly vary from man to man as the palate does; and it seems only another way of putting Hume's doctrine, that reason is not concerned with the ends of action, to say that the mere existence of a moral sentiment is in itself no reason for obeying it. A reaction, in one form or another, against the tendency to dissolve ethics into psychology was inevitable; since mankind generally could not be so far absorbed by the interest of psychological hypothesis as to forget their need of establishing practical principles. It was obvious, too, that this reaction might take place in either of the two lines of thought, which, having been peacefully allied in Clarke and Cumberland, had become distinctly opposed to each other in Butler and Hutcheson. It might either fall back on the moral principles commonly accepted, and, affirming their objective validity, endeavor to exhibit them as a coherent and complete set of ultimate ethical truths; or it might take the utility or conduciveness to pleasure, to which Hume had referred for the origin of most sentiments, as an ultimate end and standard by which these sentiments might be judged and corrected. The former is the line adopted with substantial agreement by Price, Reid, Stewart, and other members of the still existing Intuitional school; the latter method, with considerably more divergence of view and treatment, was employed independently and almost simultaneously by Paley and Bentham in both ethics and politics, and is at the present time widely maintained under the name of Utilitarianism.

Price. Price's *Review of the Chief Questions and Difficulties of Morals* was published in 1757, two years before Adam Smith's treatise. In regarding moral ideas as derived from the "intuition of truth or immediate discernment of the nature of things by the understanding," Price revives the general view of the earlier school of rational moralists; but with several specific differences which it is important to notice. Firstly, his conception of "right" and "wrong" as "single ideas" incapable of definition or analysis—the notions "right," "fit," "ought," "duty," "obligation," being coincident or identical—at least avoids the confusions into which Clarke and Wollaston had been led by pressing the analogy between ethical and physical truth. Secondly, the emotional element of the moral consciousness, on which attention had been concentrated by Shaftesbury and his followers, is henceforth distinctly recognized as accompanying the intellectual intuition, though it is carefully subordinated to it. While right and wrong, in Price's view, are "real objective qualities" of actions, moral "beauty and deformity" are subjective ideas; representing feelings which are partly the necessary effects of the perceptions of right and wrong in rational beings as such, partly due to an "implanted sense" or varying emotional susceptibility. Thus, both reason and sense or instinct co-operate in the impulse to virtuous conduct, though the rational element is primary and paramount. Price further distinguishes the perception of merit and demerit in agents as another accompaniment of the perception of right and wrong in actions; the former being, however, only a peculiar species of the latter, since, to perceive merit in any one is to perceive that it is right to reward him. It is to be observed that both Price and Reid are careful to state that the merit of the agent depends entirely on the intention or "formal rightness" of his act; a man is not blameworthy for unintended evil, though he may of course be blamed for any wilful neglect which has caused him to be ignorant of his real duty. When we turn to the subject-matter of virtue, we find that Price, in comparison with More or Clarke, is decidedly laxer in accepting and stating his ethical first principles; chiefly because he (like Reid and Stewart afterwards) appeals to common sense rather than abstract reason as the judge of moral evidence. Thus he maintains with Butler that gratitude, veracity, fulfilment of promises, and justice are obligatory independently of their conduciveness to happiness; but he does not exactly exhibit the self-evidence of the abstract proposition "that truth ought to be spoken;" he rather argues, by an inductive reference to common moral opinion, that "we cannot avoid pronouncing that there is an intrinsic rectitude in sincerity." Similarly in expounding justice,—"that part of virtue which regards property,"—he seems prepared to accept *en bloc* as ultimate the traditional principles of Roman jurisprudence, which refer the right of property to "first possession, labor, succession, and donation." We must bear in mind that Price's task is considerably more difficult than that of the earlier rational moralists; owing to the new antithesis to the view of Shaftesbury and Hutcheson by which his controversial position is complicated, so that he is specially concerned to show the existence of ultimate principles *besides* benevolence. Not that he repudiates the obligation either of rational benevolence or self-love; on the contrary, he takes more pains than Butler to demonstrate the reasonableness of either principle. "There is not anything," he says, "of which we have more undeniably an intuitive perception, than that it is 'right to pursue and promote happiness,' whether for ourselves or for others." Finally, Price, writing after the demonstration by Shaftesbury and Butler of the actuality of disinterested impulses in human nature, is bolder and clearer than Cudworth or Clarke in insisting that right actions are to be chosen because they are right by virtuous agents as such,—even going so far as to lay down that an act loses its moral worth in proportion as it is done from natural inclination.

Reid. On this latter point Reid, in his *Essays on the Active Powers of the Human Mind* (1788), adopts a more moderate and less Stoical conclusion, only maintaining that "no act can be morally good in which regard for what is right has not *some* influence." This is partly due to the fact that Reid builds more distinctly than Price on the foundation laid by Butler; especially in his acceptance of that duality of governing principles which we have noticed as a cardinal point in the latter's doctrine. Reid considers "regard for one's good on the whole" (Butler's self-love) and "sense of duty" (Butler's conscience) as two essentially distinct and co-ordinate rational principles, though naturally often comprehended under the one term, Reason. The rationality of the former principle he takes pains to explain and establish; in opposition to Hume's doctrine that it is no part of the function of reason to determine the ends which we ought to pursue, or the preference due to one end over another. He urges that the notion of "good[1] on the whole" is one which only a reasoning being can form, involving as it does abstraction from the objects of all particular desires, and comparison of past and future with present feelings; and maintains that it is a contradiction to suppose a rational being to have the notion of its Good on the Whole without a desire for it, and that such a desire must naturally regulate all particular appetites and passions. It cannot reasonably be subordinated even to the moral faculty; in fact, a man who doubts the coincidence of the two—which on religious grounds we must believe to be complete in a morally governed world—is reduced to the "miserable dilemma whether it is better to be a fool or a knave." As regards the moral faculty itself, Reid's statement coincides in the main with Price's; it is both intellectual and active, not merely perceiving the "rightness" or "moral obligation" of actions (which Reid conceives as a simple unanalyzable relation between act and agent), but also impelling the will to the performance of what is seen to be right. Both thinkers hold that this perception of right and wrong in actions is accompanied by a perception of merit and demerit in agents, and also by a specific emotion; but whereas Price conceives this emotion chiefly as pleasure or pain, analogous to that produced in the mind by physical beauty or deformity, Reid regards it chiefly as benevolent affection, esteem, and sympathy (or their opposites), for the virtuous (or vicious) agent. This "pleasurable good-will," when the moral judgment relates to a man's own actions, becomes "the testimony of a good conscience—the purest and most valuable of all human enjoyments." Reid is careful to observe that this moral faculty is not "innate" except in germ; it stands in need of "education, training, exercise (for which society is indispensable), and habit," in order to the attainment of moral truth. He does not with Price object to its being called the "moral sense," provided we understand by this a source not merely of feelings or notions, but of "ultimate truths." Here he omits to notice the important question whether the premises of moral reasoning are universal or individual judgments; as to which the use of the term "sense" seems rather to suggest the second alternative. Indeed, he seems himself quite undecided on this question; since, though he generally represents ethical method as deductive, he also speaks of the

---

[1] It is to be observed that whereas Price and Stewart (after Butler) identify the object of self-love with happiness or pleasure, Reid conceives this "good" more vaguely as including perfection *and* happiness; though he sometimes uses "good" and happiness as convertible terms, and seems practically to have the latter in view in all that he says of self-love.

"original judgment that this action is right and that wrong."

The truth is that, since Reid accepts the common moral opinion of mankind as a final test of the truth of ethical theories, the construction of a scientific method of ethics is a matter of no practical moment to him. Thus, though he offers a list of first principles, by deduction from which these common opinions may be confirmed, he does not present it with any claim to completeness. Besides maxims relating to virtue in general,—such as (1) that there is a right and wrong in conduct, but (2) only in voluntary conduct, and that we ought (3) to take pains to learn our duty, and (4) fortify ourselves against temptations to deviate from it—Reid states five fundamental axioms. The first of these is merely the principle of rational self-love, "that we ought to prefer a greater to a lesser good, though more distinct, and a less evil to a greater,"—the mention of which seems rather inconsistent with Reid's distinct separation of the "moral faculty" from "self-love." The third is merely the general rule of benevolence stated in the somewhat vague and lax Stoical phrase, that "no one is born for himself only." The fourth, again, is the merely formal principle that "right and wrong must be the same to all in all circumstances," which belongs equally to all systems of objective morality; while the fifth prescribes the religious duty of "veneration or submission to God." Thus, the only principle which might not be equally well stated by Paley or any religious utilitarian is the second (also Stoical), "that so far as the intention of nature appears in the constitution of man, we ought to act according to that intention," the vagueness[1] of which is obvious.

Dugald Stewart.

A similar incompleteness in the statement of moral principles is found if we turn to Reid's disciple, Dugald Stewart, whose *Philosophy of the Active and Moral Powers of Man* (1828) contains the general view of Reid and Price,—expounded with more neatness and grace, but without important original additions or modifications. Stewart lays stress on the obligation of justice as distinct from benevolence; but his definition of justice represents it as essentially impartiality,—a virtue which (as was just now said of Reid's fourth principle) must equally find a place in the utilitarian or any other system that lays down universally applicable rules of morality. Afterwards, however, Stewart distinguishes "integrity or honesty" as a branch of justice concerned with the rights of other men, which form the subject of "natural jurisprudence." In this department he lays down the moral axiom "that the laborer is entitled to the fruit of his own labor" as the principle on which complete rights of property are founded; maintaining that occupancy alone would only confer a transient right of possession during use. The only other principles which he discusses are veracity and fidelity to promises, gratitude being treated as a natural instinct prompting to a particular kind of just actions.

Whewell.

It will be seen that neither Reid nor Stewart offers more than a very meagre and tentative contribution to that ethical science by which, as they maintain, the received rules of morality may be rationally deduced from intuitive first principles. A more ambitious attempt in the same direction was made by Whewell in his *Elements of Morality* (1846). Whewell's general moral view differs from that of his Scotch predecessors chiefly in a point where we may trace the influence of Kant; viz., in his rejection of self-love as an independent rational and governing principle, and his consequent refusal to admit happiness, apart from duty, as a reasonable end for the individual. The moral reason, thus left in sole supremacy, is represented as enunciating five ultimate principles,—those of benevolence, justice, truth, purity, and order. With a little straining these are made to correspond to five chief divisions of Jus,—personal security (benevolence being opposed to the ill-will that commonly causes personal injuries), property, contract, marriage, and government; while the first, second, and fourth, again, regulate respectively the three chief classes of human motives,—affections, mental desires, and appetites. Thus the list, with the addition of two general principles, "earnestness" and "moral purpose," has a certain air of systematic completeness. When, however, we look closer, we find that the principle of order, or obedience to government, is not seriously intended to imply the political absolutism which it seems to express, and which English common sense emphatically repudiates; while the formula of justice is given in the tautological or perfectly indefinite proposition "that every man ought to have his own." Whewell, indeed, explains that this latter formula must be practically interpreted by positive law, though he inconsistently speaks as if it supplied a standard for judging laws to be right or wrong. The principle of purity, again, "that the lower parts of our nature ought to be subject to the higher," merely particularizes that supremacy of reason over non-rational impulses which is involved in the very notion of reasoned morality. Thus, in short, if we ask for a clear and definite fundamental intuition, distinct from regard for happiness, we find really nothing in Whewell's doctrine except the single rule of veracity (including fidelity to promises); and even of this the axiomatic character becomes evanescent on closer inspection, since it is not maintained that the rule is practically unqualified, but only that it is practically undesirable to formulate its qualifications.

Intuitional and utilitarian schools.

On the whole it must be admitted that the doctrine of the intuitional school of the present and preceding century has been developed with less care and consistency than might have been expected, in its statement of the fundamental axioms or intuitively known premises of moral reasoning. And if the controversy which this school has conducted with utilitarianism had turned principally on the determination of the matter of duty, there can be little doubt that it would have been forced into more serious and systematic effort to define precisely and completely the principles and methods on which we are to reason deductively to particular rules of conduct.[2] But in fact the difference between intuitionists and utilitarians as to the method of determining the particulars of the moral code was complicated with a more fundamental disagreement as to the very meaning of "moral obligation." This Paley and Bentham (after Locke) interpreted as merely the effect on the will of the pleasures or pains attached to the observance or violation of moral rules, combining with this the doctrine of Cumberland or Hutcheson, that "general good" or "happiness" is the final end and standard of these rules; while they eliminated all vagueness from the notion of general happiness by defining it to consist in "excess of pleasure over pain"—pleasures and pains being regarded as "differing in nothing but continuance or intensity." The utilitarian system gained an attractive air of simplicity by thus using a single perfectly clear notion—pleasure and its negative quantity pain—to answer both the fundamental questions of morals, "What is right?" and "Why should I do it?" But since there is no logical connection between the answers that have thus come to be considered as one doctrine, this apparent unity and simplicity has really hidden fundamental disagreements, and caused no little confusion in current ethical debate.

Paley.

In Paley's *Principles of Moral and Political Philosophy*[3] (1785), the link between general pleasure (the standard) and private pleasure or pain (the motive) is supplied by the conception of divine legislation. To be "obliged" is to be "urged by a violent motive resulting from the command of another;" in the case of moral obligation, the command proceeds from God, and the motive lies in the expectation of being rewarded and punished after this life. The commands of God are to be ascertained "from Scripture and the light of nature combined." Paley, however, holds that Scripture is given less to teach morality than to illustrate it by example and enforce it by new sanctions and greater certainty, and that the light of nature makes it clear that God wills the happiness of his creatures. Hence, his method in deciding moral questions is chiefly that of estimating the tendency of actions to promote or diminish the general happiness. To meet the obvious objections to this method, based on the immediate happiness caused by admitted crimes (such as "knocking a rich villain on the head") he lays stress on the necessity of general rules in any kind of legislation;[1] while, by urging the importance of forming and maintaining good habits, he partly evades the difficulty of calculating the consequences of particular actions. In this way the utilitarian method is freed from the subversive tendencies which Butler and others had discerned in it; as used by Paley, it merely explains the current moral and jural distinctions, exhibits the obvious basis of expediency which supports most of the received rules of law and morality, and furnishes a simple solution, in harmony with common sense, of some perplexing casuistical questions. Thus (*e.g.*) "natural rights" become rights of which the general observance would be useful apart from the institution of civil government; as distinguished from the no less binding "adventitious rights," the utility of which depends upon this institution. Private property is in this sense "natural," from its obvious advantages in encouraging labor, skill, preservative care; though actual rights of property depend on the general utility of conforming to the law of the land by which they are determined. So, again, many perplexities respecting the duties of veracity and good faith are solved, so as to avoid jesuitical laxities no less than superstitious scruples, by basing their obligation on the utilities general and particular of satisfying expectations deliberately produced. So, too, the general utilitarian basis of the established sexual morality is effectively expounded. We observe, however, that Paley's method is often mixed with reasonings that belong to an alien and older manner of thought; as when he supports the claim of the poor to charity by referring to the intention of mankind "when they agreed to a separation of the common fund," or when he infers that monogamy is a part of the divine design from the equal numbers of males and females born. In other cases his statement of utilitarian considerations is fragmentary and unmethodical, and tends to degenerate into loose exhortation on rather trite topics.

---

[1] *E.g.*, Reid proposes to apply this principle in favor of monogamy, arguing from the proportion of males and females born; without explaining why, if the intention of nature hence inferred excludes occasional polygamy, it does not also exclude occasional celibacy.

[2] We may observe that some recent writers, who would generally be included in this school, avoid in various ways the difficulty of constructing a code of external conduct. Sometimes they consider moral intuition as determining the comparative excellence of conflicting motives (James Martineau), or the comparative quality of pleasures chosen (Laurie), which seems to be the same view in a hedonistic garb; others hold that what is intuitively perceived is the rightness or wrongness of individual acts,—a view which obviously renders ethical reasoning practically superfluous.

[3] The originality—such as it is—of Paley's system (as of Bentham's) lies in its method of working out details rather than in its principles of construction. Paley expressly acknowledges his obligations to the original and suggestive, though diffuse and whimsical, work of Abraham Tucker (*Light of Nature Pursued*, 1768–74). In this treatise, as in Paley's, we find "every man's own satisfaction, the spring that actuates all his motives," connected with "general good, the root whereout all our rules of conduct and sentiments of honor are to branch," by means of natural theology demonstrating the "unniggardly goodness of the Author of nature." Tucker is also careful to explain that satisfaction or pleasure is "one and the same in kind, however much it may vary in degree, . . . whether a man is pleased with hearing music, seeing prospects, tasting dainties, performing laudable actions, or making agreeable reflections," and again that by "general good" he means "quantity of happiness," to which "every pleasure that we do to our neighbor is an addition." There is, however, in Tucker's theological link between private and general happiness a peculiar ingenuity which Paley's common sense has avoided. He argues that men having no free-will have really no desert; therefore the divine equity must ultimately distribute happiness in equal shares to all; therefore I must ultimately increase my own happiness most by conduct that adds most to the general fund which Providence administers.

Bentham and his school.

In unity, consistency, and thoroughness of method, Bentham's utilitarianism has a decided superiority over Paley's. He throughout considers actions solely in respect of their pleasurable and painful consequences, expected or actual; and he fully recognizes the need of making an exhaustive and systematic register of these consequences, free from the influences of common moral opinion, as expressed in the "eulogistic" and "dyslogistic" terms in ordinary use. Further, the effects that he estimates are all of a definite, palpable, empirically ascertainable quality; they are such pleasures and pains as most men feel and all can observe to be felt, so that all political or moral inferences drawn by Bentham's method lie open at every point to the test of practical experience. Every one, it would seem, can tell what value he sets on the pleasures of alimentation, sex, the senses generally, wealth, power, curiosity, sympathy, antipathy (malevolence), the goodwill of individuals or of society at large, and on the corresponding pains, as well as the pains of labor and organic disorders;[2] and can pretty well guess the rate at which they are valued by others; therefore if it be once granted that all actions are determined by pleasures and pains, and are to be tried by the same standard, the art both of legislation and of private conduct is apparently placed on a broad, simple, and clear empirical basis. Bentham, no doubt, seems to go beyond the limits of mundane experience in recognizing "religious" pains and pleasures in his fourfold division of sanctions, side by side with the "physical," "political," and "moral" or "social;" but the truth is that he does not seriously take account of them, except in so far as religious hopes and fears are motives actually operating, which therefore admit of being observed and measured as much as any other motives. He does not himself use the will of an omnipotent and benevolent being as a means of logically connecting individual and general happiness. He thus undoubtedly simplifies his system, and avoids the doubtful inferences from nature and Scripture in which Paley's position is involved; but this gain is dearly purchased. For in answer to the question that immediately arises, How then is the maximum happiness of any individual shown to be always conjoined with the maximum general happiness? he is obliged to admit that "the only interests which a man is at all times sure to find adequate motives for consulting are his own." Indeed, in many parts of his vast work, in the department of legislative and constitutional theory, it is rather assumed that the interests of some men will continually conflict with those of their fellows, unless we alter the balance of prudential calculation by a careful readjustment of penalties. But on this assumption a satisfactory system of private conduct on utilitarian principles cannot be constructed until legislative and constitutional reform has been perfected. And, in fact, "private ethics," as conceived by Bentham, does not exactly expound such a system; but rather exhibits the coincidence, *so far as it extends*, between private and general happiness, in that part of each man's conduct that lies beyond the range of useful legislation. It was not his place, as a practical philanthropist, to dwell on the defects in this coincidence;[3] and since what men generally expect from a moralist is a completely reasoned account of what they ought to do, it is not surprising that some of Bentham's disciples should have either ignored or endeavored to supply the gap in his system. One section of the school even maintained it to be a cardinal doctrine of utilitarianism that a man always gains his own greatest happiness by promoting that of others; another section, represented by John Austin, apparently returned to Paley's position, and treated utilitarian morality[4] as a code of divine legislation; others, with Grote, are content to abate the severity of the claims made by "general happiness" on the individual, and to consider utilitarian duty as practically limited by reciprocity; while J. S. Mill, who has done more than any other member of the school to spread and popularize utilitarianism in ethics and politics, exalts the "moral hero" for voluntarily sacrificing his own happiness to promote that of others—a phenomenon, it should be observed, which in Bentham's view is not even possible.

Varieties of utilitarian doctrine.

The fact is that there are several different ways in which a utilitarian system of morality may be used, without deciding whether the sanctions attached to it are always adequate. (1) It may be presented as practical guidance to all who choose "general good" as their ultimate end, whether they

---

But in fact the outline of Paley's utilitarianism is to be found a generation earlier,—in Gay's dissertation prefixed to Law's edition of King's *Origin of Evil*,—as the following extracts will show:—"The idea of virtue is the conformity to a rule of life, directing the actions of all rational creatures with respect to each other's happiness; to which every one is always obliged. . . . Obligation is the necessity of doing or omitting something in order to be happy. . . . Full and complete obligation which will extend to all cases can only be that arising from the authority of God. . . . The will of God [so far as it directs behavior to others] is the immediate rule or criterion of virtue; . . . but it is evident from the nature of God that he could have no other design in creating mankind than their happiness; and therefore he wills their happiness; therefore that my behavior so far as it may be a means to the happiness of mankind should be such; so this happiness of mankind may be said to be the criterion of virtue once removed."

The same dissertation also contains the germ of Hartley's system, as we shall presently notice.

[1] It must be allowed that Paley's application of this argument is somewhat loosely reasoned, and does not sufficiently distinguish the consequences of a single act of beneficent manslaughter from the consequences of a general permission to commit such acts.

[2] This list gives twelve out of the fourteen classes in which Bentham arranges the springs of action, omitting the religious sanction (mentioned afterwards), and the pleasures and pains of self-interest, which include all the other classes except sympathy and antipathy.

[3] In the *Deontology* published by Bowring from MSS left after Bentham's death, the coincidence is asserted to be complete; but it seems doubtful whether this can be accepted as Bentham's real doctrine, even in his later days.

[4] It should be observed that Austin, after Bentham, more frequently uses the term "moral" to connote what he more distinctly calls "positive morality," the code of rules supported by common opinion in any society.

do so on religious grounds, or through the predominance in their minds of impartial sympathy, or because their conscience acts in harmony with utilitarian principles, or for any combination of these or any other reasons; or (2) it may be offered as a code to be obeyed not absolutely, but only so far as the coincidence of private and general interest may in any case be judged to extend; or again (3) it may be proposed as a standard by which men may reasonably agree to praise and blame the conduct of others, even though they may not always think fit to act on it. We may regard morality as a kind of supplementary legislation, supported by public opinion, which we may expect the public, when duly enlightened, to frame in accordance with the public interest. Still, even from this point of view, which is that of the legislator or social reformer rather than the moral philosopher, our code of duty must be greatly influenced by our estimate of the degrees in which men are normally influenced by self-regard (in its ordinary sense of regard for interests not sympathetic) and by sympathy or benevolence, and of the range within which sympathy may be expected to be generally effective. Thus, for example, the moral standard for which a utilitarian will reasonably endeavor to gain the support of public opinion must be essentially different in quality, according as he holds with Bentham that nothing but self-regard will "serve for diet," though "for a dessert benevolence is a very valuable addition;" or with J. S. Mill that disinterested public spirit should be the prominent motive in the performance of all socially useful work, and that even hygienic precepts should be inculcated, not chiefly on grounds of prudence, but because "by squandering our health we disable ourselves from rendering services to our fellow-creatures."

J. S. Mill.

Not less important is the interval that separates Bentham's polemical attitude towards the moral sense from Mill's conciliatory position, that "the mind is not in a state conformable to utility unless it loves virtue as a thing desirable in itself." Such love of virtue Mill holds to be in a sense natural, though not an ultimate and inexplicable fact of human nature; it is to be explained by the "Law of Association" of feelings and ideas, through which objects originally desired as a means to some further end come to be directly pleasant or desirable. Thus, the miser first sought money as a means to comfort, but ends by sacrificing comfort to money; and similarly though the first promptings to justice (or any other virtue) spring from the non-moral pleasures gained or pains avoided by it, through the link formed by repeated virtuous acts the performance of them ultimately comes to have that immediate satisfaction attached to it which we distinguish as moral. Indeed, the acquired tendency to virtuous conduct may become so strong that the habit of willing it may continue, "even when the reward which the virtuous man receives from the consciousness of well-doing is anything but an equivalent for the sufferings he undergoes or the wishes he may have to renounce." It is thus that the before-mentioned self-sacrifice of the moral hero is conceived by Mill to be possible and actual. The moral sentiments, on this view, are not phases of self-love as Hobbes held; nor can they be directly identified with sympathy, either in Hume's way or in Adam Smith's; in fact, though apparently simple they are really derived in a complex manner from self-love and sympathy combined with more primitive impulses. Justice (*e.g.*) is regarded by Mill as essentially resentment moralized by enlarged sympathy and intelligent self-interest; what we mean by injustice is harm done to an assignable individual by a breach of some rule for which we desire the violator to be punished, for the sake both of the person injured and of society at large, including ourselves. As regards moral sentiments generally, the view suggested by Mill is more definitely given by the chief living representative of the associationist school, Professor Bain; by whom the distinctive characteristics of conscience are traced to "education under government or authority," though prudence, disinterested sympathy, and other emotions combine to swell the mass of feeling vaguely denoted by the term moral. The combination of antecedents is somewhat differently given by different writers; but all agree in representing the conscience of any individual as naturally correlated to the interests of the community of which he is a member, and thus a natural ally in enforcing utilitarian rules, or even a valuable guide when utilitarian calculations are difficult and uncertain.

Association and evolution.

This substitution of hypothetical history for direct analysis of the moral sense is really older than the utilitarianism of Paley and Bentham, which it has so profoundly modified. The effects of association in modifying mental phenomena were noticed by Locke, and made a cardinal point in the metaphysic of Hume; who also referred to the principle slightly in his account of justice and other "artificial" virtues. Some years earlier, Gay,[1] admitting Hutcheson's proof of the actual disinterestedness of moral and benevolent impulses, had maintained that these (like the desires of knowledge or fame, the delight of reading, hunting, and planting, etc.) were derived from self-love by "the power of association." But a thorough and systematic application of the principle to ethical psychology is first found in Hartley's *Observations on Man* (1748). Hartley, too, was the first to conceive association as producing, instead of mere cohesion of mental phenomena, a quasi-chemical combination of these into a compound apparently different from its elements. He shows elaborately how the pleasures and pains of "imagination, ambition, self-interest, sympathy, theopathy, and the moral sense" are developed out of the elementary pleasures and pains of sensation; by the coalescence into really complex but apparently single ideas of the "miniatures" or faint feelings which the repetition of sensations contemporaneously or in immediate succession tends to produce in cohering groups. His theory assumes the correspondence of mind and body, and is applied *pari passu* to the formation of ideas from sensations, and of "compound vibratiuncles in the medullary substance" from the original vibrations that arise in the organ of sense.[2] The same general view was afterwards developed on the psychical side alone by James Mill in his *Analysis of the Human Mind*, with much vigor and clearness. The whole theory has been persistently controverted by writers of the intuitional school, who (unlike Hartley) have usually thought that this derivation of moral sentiments from more primitive feelings would be detrimental to the authority of the former. The chief argument against this theory has been based on the early period at which these sentiments are manifested by children, which hardly allows time for association to produce the effects ascribed to it. This argument has been met in recent times by the application to mind of the physiological theory of heredity, according to which changes produced in the mind (brain) of a parent, by association of ideas or otherwise, tend to be inherited by his offspring; so that the development of the moral sense or any other faculty or susceptibility of existing man may be hypothetically carried back into the prehistoric life of the human race, without any change in the manner of derivation supposed. At present, however, the theory of heredity is usually held in conjunction with Darwin's theory of natural selection; according to which different kinds of living things in the course of a series of generations come gradually to be endowed with organs, faculties, and habits tending to the preservation of the individual or species under the conditions of life in which it is placed. Thus we have a new zoological factor in the history of the moral sentiments; which, though in no way opposed to the older psychological theory of their formation through coalescence of more primitive feelings, must yet be conceived as controlling and modifying the effects of the law of association by preventing the formation of sentiments other than those tending to the preservation of human life. The influence of the Darwinian theory, moreover, has extended from historical psychology to ethics, tending to substitute "preservation of the race under its conditions of existence" for "happiness" as the ultimate end and standard of virtue.

Free-will.

Before concluding this sketch of the development of English ethical thought from Hobbes to the present time, it will be well to notice briefly the views held by different moralists on the question of free-will,—so far, that is, as they have been put forward as ethically important. We must first distinguish three meanings in which "freedom" is attributed to the will or "inner self" of a human being, viz., (1) the general power of choosing among different alternatives of action without a motive, or against the resultant force of conflicting motives; (2) the power of choice between the promptings of reason and those of appetites (or other non-rational impulses) when the latter conflict with reason; (3) merely the quality of acting rationally in spite of conflicting impulses, however strong, the *non posse peccare* of the mediæval theologians.[1] It is obvious that "freedom" in this third sense is in no way incompatible with complete determination; and, indeed, is rather an ideal state after which the moral agent ought to aspire, than a property which the human will can be said to possess. In the first sense, again, as distinct from the second, the assertion of "freedom" has no ethical significance, except in so far as it introduces a general uncertainty into all our inferences respecting human conduct. Even in the second sense it hardly seems that the freedom of a man's will can be an element to be considered in examining what it is right or best for him to do (though of course the clearest convictions of duty will be fruitless if a man has not sufficient self-control to enable him to act on them); it is rather when we ask whether it is just to punish him for wrong-doing that it seems important to know whether he could have done otherwise. But in spite of the strong interest taken in the theological aspect of this question by the Protestant divines of the 17th century, it does not appear that English moralists from Hobbes to Hume laid any stress on the relation of free-will either to duty generally or to justice in particular. Neither the doctrine of Hobbes, that deliberation is a mere alternation of competing desires, voluntary action immediately following the "last appetite," nor the hardly less decided Determinism of Locke, who held that the will is always moved by the greatest present uneasiness, appeared to either author to require any reconciliation with the belief in human responsibility. Even in Clarke's system, where Indeterminism is no doubt a cardinal notion, its importance is metaphysical rather than ethical; Clarke's view being that the apparently arbitrary particularity in the constitution of the cosmos is really only explicable by reference to creative free-will. In the ethical discussion of Shaftesbury and sentimental moralists generally this question drops naturally out of sight; and the cautious Butler tries to exclude its perplexities as far as possible from the philosophy of practice. But since the reaction, led by Price and Reid, against the manner of philosophizing that had culminated in Hume, free-will has been generally maintained by the intuitional school to be an essential point of ethics; and, in fact, it is naturally connected with the judgment of good and ill desert which these writers give as an essential element in their analysis of the moral consciousness. An irresistible motive, it is forcibly said, palliates or takes away guilt; no one can blame himself for yielding to necessity, and no one can properly be punished for what he could not have prevented. In answer to this argument some necessarians have admitted that punishment can only be legitimate if it be beneficial to the person punished; others, again, have held that the lawful use of force is to restrain lawless force; but most of those who reject free-will defend punishment on the ground of its utility in deterring others from crime, as well as in correcting or restraining the criminal on whom it falls.

---

[1] In the before-mentioned dissertation. *Cf.* note 3 to p. 532. Hartley refers to this treatise as having supplied the starting-point for his own system.

[2] It should be noticed that Hartley's sensationalism is far from leading him to exalt the corporeal pleasures. On the contrary, he tries to prove elaborately that they (as well as the pleasures of imagination, ambition, self-interest) cannot be made an object of primary pursuit without a loss of happiness on the whole,—one of his arguments being that these pleasures occur earlier in time, and "that which is prior in the order of nature is always less perfect than that which is posterior."

French influence on English ethics.

In the preceding sketch we have traced the course of English ethical speculation without bringing it into relation with contemporary European thought on the same subject. And in fact almost all the systems described, from Hobbes downward, have been of essentially native growth, showing hardly any traces of foreign influence. We may observe that ethics is the only department in which this result appears. The physics and psychology of Descartes were much studied in England, and his metaphysical system was certainly the most important antecedent of Locke's; but Descartes hardly touched ethics proper. So again the controversy that Clarke conducted with Spinoza, and afterwards with Leibnitz, was entirely confined to the metaphysical region. Catholic France was a school for Englishmen in many subjects, but not in morality; the great struggle between Jansenists and Jesuits had a very remote interest for us. It was not till near the close of the 18th century that the impress of the French revolutionary philosophy begins to manifest itself on this side the Channel; and even then its influence is mostly political rather than ethical. It is striking to observe how even in the case of writers such as Godwin, who were most powerfully affected by the French political movement, the moral basis, on which the new social order of rational and equal freedom is constructed, is almost entirely of native origin; even when the tone and spirit are French, the forms of thought and manner of reasoning are still purely English. In the derivation of Benthamism alone—which, it may be observed, first became widely known in the French paraphrase of Dumont—an important element is supplied by the works of a French writer, Helvetius; as Bentham himself was fully conscious. It was from Helvetius that he learnt that, men being universally and solely governed by self-love, the so-called moral judgments are really the common judgments of any society as to its common interests; that it is therefore futile on the one hand to propose any standard of virtue, except that of conduciveness to general happiness, and on the other hand useless merely to lecture men on duty and scold them for vice; that the moralist's proper function is rather to exhibit the coincidence of virtue with private happiness; that, accordingly, though nature has bound men's interests together in many ways, and education by developing sympathy and the habit of mutual help may much extend the connection, still the most effective moralist is the legislator, who by acting on self-love through legal sanctions may mould human conduct as he chooses. These few simple doctrines give the ground plan of Bentham's indefatigable and life-long labors.

Helvetius.

Comte.

So again, in the modified Benthamism which the persuasive exposition of J. S. Mill recently made popular in England, the influence of a French thinker, Auguste Comte (*Philosophie Positive*, 1829–42, and *Système de Politique Positive*, 1851–4) appears as the chief modifying element. This influence, so far as it has affected moral as distinct from political speculation, has been exercised primarily through the general conception of human progress; which, in Comte's view, consists in the ever-growing preponderance of the distinctively human attributes over the purely animal, social feelings being ranked highest among human attributes, and highest of all the most universalized phase of human affection, the devotion to humanity as a whole. Accordingly, it is the development of benevolence in man, and of the habit of "living for others," which Comte takes as the ultimate aim and standard of practice, rather than the mere increase of happiness. He holds, indeed, that the two are inseparable, and that the more *altruistic* any man's sentiments and habits of action can be made, the greater will be the happiness enjoyed by himself as well as by others. But he does not seriously trouble himself to argue with egoism, or to weigh carefully the amount of happiness that might be generally attained by the satisfaction of egoistic propensities duly regulated; a supreme unquestioning self-devotion, in which all personal calculations are suppressed, is an essential feature of his moral ideal. Such a view is almost diametrically opposed to Bentham's conception of normal human existence; the newer utilitarianism of Mill represents an endeavor to find the right middle path between the two extremes.

It is to be observed that, in Comte's view, devotion to humanity is the principle not merely of morality but of religion; *i.e.*, it should not merely be practically predominant, but should be manifested and sustained by regular and partly symbolical forms of expression, private and public. This side of Comte's system, however, and the details of his ideal reconstruction of society, in which this religion plays an important part, have had but little influence either in England or elsewhere. It is more important to notice the general effect of his philosophy on the method of determining the particulars of morality as well as of law (as it ought to be). In the utilitarianism of Paley and Bentham the proper rules of conduct, moral and legal, are determined by comparing the imaginary consequences of different modes of regulation on men and women, conceived as specimens of a substantially uniform and unchanging type. It is true that Bentham expressly recognizes the varying influences of climate, race, religion, government, as considerations which it is important for the legislator to take into account; but his own work of social construction was almost entirely independent of such considerations, and his school generally appear to have been convinced of their competence to solve all important ethical and political questions for human beings of all ages and countries, without regard to their specific differences. But in the Comtian conception of social science, of which ethics and politics are the practical application, the knowledge of the laws of the evolution of society is of fundamental and continually increasing importance; humanity is regarded as having passed through a series of stages, in each of which a somewhat different set of laws and institutions, customs and habits, is normal and appropriate. Thus present man is a being that can only be understood through a knowledge of his past history; and any effort to construct for him a moral and political ideal, by a purely abstract and unhistorical method, must be necessarily futile; whatever modifications may at any time be desirable in positive law and morality can only be determined by the aid of "social dynamics." This view extends far beyond the limits of Comte's special school or sect, and, indeed, seems to be very widely accepted among educated persons at the present day.

---

[1] It may be observed that in the view of Kant and others (2) and (3) are somewhat confusingly blended.

German influence on English ethics.

When we turn from French philosophy to German, we find the influence of the latter on English ethical thought almost insignificant until a very recent period. In the 17th century, indeed, the treatise of Puffendorf on the *Law of Nature*, in which the general view of Grotius was restated with modifications, partly designed to effect a compromise with the new doctrine of Hobbes, seems to have been a good deal read at Oxford and elsewhere. Locke includes it among the books necessary to the complete education of a gentleman. But the subsequent development of the theory of conduct in Germany dropped almost entirely out of the cognizance of Englishmen; even the long dominant system of Wolff (d. 1754), imposing in its elaborate and complete construction, was hardly known to our best informed writers. Nor did the greater fame and more commanding genius of Kant (1724–1804) procure him any English disciples of note, or even lead to the serious study of his ethical system by English moralists, until the second quarter of the present century. We find, however, distinct traces of Kantian influence in Whewell and other recent writers of the intuitional school; and the continually increasing interest in the products of the German mind which Englishmen have shown during the last 40 years has caused the works of Kant to be so widely known that it would hardly be fit to close the present article without some account of his ethical doctrines.

Kant.

The English moralist with whom Kant has most affinity is Price; in fact, Kantism, in the ethical thought of modern Europe, holds a place somewhat analogous to that occupied by the teaching of Price and Reid among ourselves. Kant, like Price and Reid, holds that the reason declares the immediate obligation of certain kinds of conduct, or (to use his phrase) issues "categorical imperatives." Like Price he holds that an action is not good unless done from a good motive, and that this motive must be essentially different from natural inclination of any kind; duty, to be duty, must be done for duty's sake; and he argues, with more subtlety than Price or Reid, that though a virtuous act is no doubt pleasant to the virtuous agent, and any violation of duty painful, this moral pleasure (or pain) cannot strictly be the motive to the act, because it follows instead of preceding the recognition of our obligation to do it.[1] With Price, again, he holds that rightness of intention and motive is not only an indispensable condition or element of the rightness of an action, but actually the sole determinant of its moral worth; but with more philosophical penetration he draws the inference—of which the English moralist does not seem to have dreamt—that there can be no separate rational principles for determining the "material" rightness of conduct, as distinct from its "formal" rightness; and therefore that all rules of duty must admit of being deduced from the one general principle that duty ought to be done for duty's sake. This deduction is the most original part of Kant's doctrine. The dictates of reason, he points out, must necessarily be addressed to all rational beings as such; hence, my intention cannot be right unless I am prepared to will the principle on which I act to be a universal law. He considers that this fundamental rule or imperative "act on a maxim which thou canst will to be law universal" supplies a sufficient criterion for determining particular duties in all cases. The rule excludes wrong conduct with two degrees of stringency. Some offences, such as breach of contract, we cannot even conceive universalized; as soon as every one broke promises no one would make them. Other maxims, such as that of leaving persons in distress to shift for themselves, we can easily conceive to be universal laws, but we cannot without contradiction will them to be such; for when we are ourselves in distress we cannot help desiring that others should help us.

Another important peculiarity of Kant's doctrine is his development of the connection between duty and free-will. He holds that it is through our moral consciousness that we know that we are free; in the cognition that I ought to do what is right because it is right and not because I like it, it is implied that this purely rational volition is possible; that my action can be determined, not "mechanically," through the necessary operation of the natural stimuli of pleasurable and painful feelings, but in accordance with the laws of my true, reasonable self. The realization of reason, or of human wills so far as rational, thus presents itself as the absolute end of duty; and we get, as a new form of the fundamental practical rule, "act so as to treat humanity, in thyself or any other, as an end always, and never as a means only." We may observe, too, that the notion of freedom connects ethics with jurisprudence in a simple and striking manner. The fundamental aim of jurisprudence is to realize external freedom by removing the hinderances imposed on each one's free action through the interferences of other wills. Ethics shows how to realize internal freedom by resolutely pursuing rational ends in opposition to those of natural inclination. But what practicable ends are there which reason prescribes, and which can therefore be stated absolutely as ends at which human beings ought to aim whatever their actual desires may be? There are two such ends, Kant holds,—perfection and happiness; more precisely what we are morally bound to seek is perfection for ourselves and happiness for others; since (1) no one can directly promote the moral perfection of others, depending as it does on free choice of right; and (2) one's own happiness being necessarily an object of natural desire cannot also be regarded as a duty. The latter limitation contrasts strikingly with the view of Butler and Reid, that man, as a rational being, is under a "manifest obligation" to seek his own interest. The difference, however, is not really so great as it seems; since in another part of his system Kant fully recognizes the reasonableness of self-love. Though duty, in his view, excludes regard for private happiness, the *summum bonum* is not duty alone, but duty and happiness combined; the demand for happiness as the reward of duty is so essentially reasonable that we must postulate a universal connection between the two is the order of the universe; indeed, the practical necessity of this postulate is the only adequate rational ground that we have for believing in the existence of God.

Hegel.

Before the ethics of Kant had begun to be seriously studied in England, the rapid and remarkable development of metaphysical view and method of which the three chief stages are represented by Fichte, Schelling, and Hegel respectively had already taken place; and the system of the latter was occupying the most prominent position in the philosophical thought of Germany.[2] Hegel's ethical doctrine (expounded chiefly in his *Philosophie des Rechts*, 1821) shows a close affinity, and also a striking contrast to Kant's. He holds, with Kant, that duty or good conduct consists in the conscious realization of the free reasonable will, which is essentially the same in all rational beings. But in Kant's view the universal content of this will is only given in the formal condition of "only acting as one can desire all to act," to be subjectively applied by each rational agent to his own volition; whereas Hegel conceives the universal will as objectively presented to each man in the laws, institutions, and customary morality of the community of which he is a member. Thus, in his view, not merely natural inclinations towards pleasures, or the desires for selfish happiness, require to be morally resisted; but even the prompting of the individual's conscience, the impulse to do what seems to him right, if it comes into conflict with the common sense of his community. It is true that Hegel regards the conscious effort to realize one's own conception of good as a higher stage of moral development than the mere conformity to the jural rules establishing property, maintaining contract, and allotting punishment to crime, in which the universal will is first expressed; since in such conformity this will is only accomplished accidentally by the outward concurrence of individual wills, and is not essentially realized in any of them. He holds, however, that this conscientious effort is self-deceived and futile, is even the very root of moral evil, except it attains its realization in harmony with the objective social relations in which the individual finds himself placed. Of these relations the first grade is constituted by the family, the second by civil society, and the third by the state, the organization of which is the highest manifestation of universal reason in the sphere of practice.

---

[1] Singularly enough, the English writer who approaches most nearly to Kant on this point is the utilitarian Godwin, in his *Political Justice*. In Godwin's view, reason is the proper motive to acts conducive to general happiness: reason shows me that the happiness of a number of other men is of more value than my own; and the perception of this truth affords me at least *some* inducement to prefer the former to the latter. And supposing it to be replied that the motive is really the moral uneasiness involved in choosing the selfish alternative, Godwin answers that this uneasiness, though a "constant step" in the process of volition, is a merely "accidental" step,—"I feel pain in the neglect of an act of benevolence, because benevolence is judged by me to be conduct which it becomes me to adopt."

[2] In Kantism, as we have partly seen, the most important ontological beliefs—in God, freedom, and immortality of the soul—are based on necessities of ethical thought. In Fichte's system the connection of ethics and metaphysics is still more intimate; indeed, we may compare it in this respect to Platonism; as Plato blends the most fundamental notions of each of these studies in the one idea of good, so Fichte blends them in the one idea free-will. "Freedom," in his view, is at once the foundation of all being and the end of all moral action. In the systems of Schelling and Hegel ethics falls again into a subordinate place; indeed, the ethical view of the former is rather suggested than completely developed. Neither Fichte nor Schelling has exercised more than the faintest and most indirect influence on ethical philosophy in England; it therefore seems best to leave the ethical doctrines of each to be explained in connection with the rest of his system.

Hegelianism appears as a distinct element in English ethical thought at the present day; but the direct influence of Hegel's system is perhaps less important than that indirectly exercised through the powerful stimulus which it has given to the study of the historical development of human thought and human society. According to Hegel, the essence of the universe is a process of thought from the abstract to the concrete; and a right understanding of this process gives the key for interpreting the evolution in time of European philosophy. So again, in his view, the history of mankind is a history of the necessary development of the free spirit through the different forms of political organization; the first being that of the Oriental monarchy, in which freedom belongs to the monarch only; the second, that of the Græco-Roman republics, in which a select body of free citizens is sustained on a basis of slavery; while finally in the modern societies, sprung from the Teutonic invasion of the decaying Roman empire, freedom is recognized as the natural right of all members of the community. The effect of the lectures (posthumously edited) in which Hegel's "Philosophy of History" and "History of Philosophy" were expounded has extended far beyond the limits of his special school; indeed, the present predominance of the historical method in all departments of the theory of practice is not a little due to their influence. What place the study of history ought to take in the systematic establishment of fundamental ethical principles or of particular moral rules is, however, still a matter of eager controversy. (H. S.)

ETHIOPIA, or ÆTHIOPIA, in Greek *Αἰθιοπία*, the ancient classical designation of a country and kingdom of North-eastern Africa, lying immediately to the S. of Egypt, and extending eastwards to the Red Sea, but with no definitely marked boundaries in any other direction. According to the "folk's etymology" of the Greeks, the name was equivalent to the "land of the scorched faces," from *αἴθειν*, to burn, and *ὤψ*, the countenance, and this supposed derivation doubtless reacted on the employment of the word, and increased the vagueness of its meaning; but in all probability it was really, like the name of Egypt itself, a corruption of some Egyptian original now unknown. The knowledge of this country possessed by the earlier Greeks was extremely slight, and greatly corrupted by mythical additions. To the generation among whom the Homeric poems took their rise the Ethiopians were the remotest inhabitants of the world, and received the gods themselves as familiar guests. They are twice mentioned by Hesiod, who calls their king by the Egyptian name of Memnon. Herodotus acquired a considerable amount of information about their connection with Egypt, and Democritus is said to have travelled as far south as Meroe, and to have written an account of its hieroglyphics; but it was not till the invasion of Ptolemy Philadelphus that the Greeks began to be familiar with the country. From Herodotus downwards we hear of a great many separate tribes, most of whom are designated by Greek epithets descriptive of some real or supposed peculiarity, as the Ichthyophagi or Fish-eaters, the Macrobii or Long-livers, the Troglodytes or Cave-dwellers. To only a few of them can their proper geographical position be assigned, and of none of them can we with certainty determine the ethnographical affinities. The name Ethiopian, indeed, must be regarded not as an ethnographical but as a politico-geographical designation. It has been applied, both in ancient and modern times, to peoples of different race who have occupied the country to the south of Egypt and the south-western part of Arabia, much in the same way as the name Englishman is used by foreigners for any native of the British Islands, whether he be of Germanic or Celtic descent; and in this respect it probably differs from the quasi-synonymous Cushite of Hebrew ethnology and the An of the Egyptian inscriptions. The inhabitants of Meroe or Southern Ethiopia were a reddish-brown people, and are so represented on the monuments; but they were surrounded by, and perhaps intermingled with, a number of dark-skinned tribes, whose effigies indicate affinity with the negro. Modern research enables us to trace the main outlines of Ethiopian history, but with the same indefiniteness of chronology which attaches to so much of the history of Egypt. Of its earlier epochs we are profoundly ignorant. The Greeks had a tradition that the Egyptians were indebted to the Ethiopians for the first impulse of their civilization; but recent investigators maintain that the relation between the two peoples must have been exactly the reverse of this, and their view is supported by the fact that as we advance up the river the monuments are evidently of later date and poorer workmanship, as if the southern builders were only second-rate imitators of their northern predecessors (*cf.* Brugsch, *Geschichte Ægypten's*, 1877). The Pharaohs of the XII. Egyptian Dynasty—the Usurtesens or Osortasens and Amenemhats—repulsed the encroachments of the Ethiopians and invaded their country. By Usurtesen III. a frontier fortress was erected at Semneh; and he forbade the people to the south to enter Egypt except for the purpose of trading in cattle. During the XVIII. Dynasty we find the kings of Egypt partly in friendly and partly in hostile relations with their Ethiopian neighbors. Aahmes married an Ethiopian princess, and received the assistance of her family in the expulsion of the shepherd kings. Amenhotep (Amenophis) I. his son, and Thothmes (Tuthmosis) I. his grandson, both extended the Egyptian dominion towards the south, and the supremacy of Tuthmosis III. seems to have been widely acknowledged throughout the Ethiopian region. When Amenhotep II., as we are informed by an inscription in the Nubian temple of Amadas, brought back from his conquests the dead bodies of the kings he had slain, one of them was sent to adorn the walls of Napata, the Ethiopian city now identified with Jebel Barkal. Amenhotep III., Horemhebi, and the more warlike Rameses or Ramessu I. are all mentioned as in possession of the Ethiopian supremacy, but as engaged from time to time in wars within the region. Amenhotep III. founded at Napata a great fortress-temple for the god Amon-ra of Thebes. A general revolt took place against Ramses II. and the importance of the wars that followed is shown by the extensive sculptures and paintings in regard to them still preserved at Ipsambul (Abu-simbel) and Beit Walli. During the XXII. Egyptian Dynasty the independence and power of the principal Ethiopian potentate had increased so much that Azerch-Amen, of Napata, the Zerah of the Biblical narrative, conquered all the valley of the Nile, and advanced against Syria and Judah; the defeat, however, inflicted on him at Zephathah by King Asa was so complete that he withdrew again within his original frontiers. Piankhi Meriamen, the priest-king of Napata, whose family had an Egyptian origin, took advantage of the confusion into which Egypt had fallen during the XXIII. Dynasty, and succeeded in establishing his authority; and for several generations Ethiopian influence was predominant in Egypt. Tirhakah especially was a monarch of great power, as is attested by his monuments at Napata and elsewhere. The great Egyptian Psametik was enabled by foreign assistance to restore a native dynasty; but the excessive favor which he showed to those who had helped him to his throne so displeased the Egyptian military caste that they emigrated to Ethiopia to the number, according to Herodotus, of 240,000. At Ipsambul (Abu-simbel) there is a Greek inscription on one of the great colossi of Ramses purporting to have been engraved by the Greek mercenaries who accompanied the expedition of Psametik against his runaway subjects. The Persian invader Cambyses, who brought the Egyptian independence to a close, failed in his attack on the Ethiopian kingdom; but the change in the condition of Egypt helped to open up Ethiopia to Greek enterprise and influence. Under the Ptolemies various Greek colonies—Dire-Berenices, Adulis, Arsinoe—were established on the Ethiopian coast of the Red Sea, and Greek learning was introduced into the Ethiopian court. Ptolemy Philadelphus invaded the country, but came to terms with the king, Ergamenes or Arkamen, who is reported to have relieved the royal power from the ecclesiastical bondage under which it had long suffered, by putting the priests to death and plundering their temples. Arkamen's name occurs on the monuments at Debod or Tabet. In the reign of Augustus, C. Petronius had to defend the Egyptian frontiers against an invasion under Queen Candace: in the second campaign he extorted the submission of the country, which continued nominally Roman till the reign of Diocletian. A garrison was established at Primis or Ibrim, and a troop of German horse had its headquarters at Pselchis. There is still a very perfect Roman camp at Mehendi, to the south of Hierasykaminos. About the 1st century of the Christian era a new kingdom seems to have grown up at Axume. The king Zoskales is mentioned by the author of the *Periplus of the Erythrean Sea*, who also tells us that he was acquainted with Greek; he may be identified with the Za Hagalé or Hekla of the Ethiopian list of kings. In the sixth century the Christians of Yemen, being oppressed by the dynasty of Jewish proselytes who at that time held the throne of the Himyarites, asked and obtained the assistance of the Axumite monarch; but the Ethiopian sovereignty thus established only lasted for about seventy years.

Compare Egypt, vol. vii. pp. 633–648; Abyssinia, vol. i., and the works of Salt, etc., there referred to; and in addition Lenormant, *Manuel de l'histoire orientale*; *Records of the Past*, vol. iv.; Vivien de Saint Martin, "Eclairc. geogr. et hist. sur l'inscription d'Adulis," in *Journal Asiatique*, 1863, published separately in 1864, and his *Le Nord de l'Afrique dans l'antiquité grecque et romaine*, 1863.

Ethiopian, or Geez, is the name given in modern philology to a language of the Semitic family which is still used in Abyssinia for literary and ecclesiastical purposes. It shows the closest affinity in grammatical structure with Arabic. The verb has ten conjugations, of which two are peculiar, and the remaining eight analogous to as many of the ten Arabic conjugations. The noun presents a greater similarity to the Hebrew noun, though at the same time it has decidedly Arabic characteristics. There is no dual form either in noun or verb. About a third of the vocables of the language have been traced to Arabic roots, while others find their counterparts and kindred in Aramaic and Hebrew. A considerable number of words have been imported from foreign tongues—some as mere exotics by translators and scholars, but many others through direct popular intercourse with foreign nations. Aramaic, Hebrew, and Greek have been chiefly laid under contribution, the last especially for words technical to Christianity. Of course it is often difficult to decide in the case of Aramaic and Arabic vocables whether they are real borrowings since the differentiation of the languages, or are part of the original common stock of the Semitic. There are at least two modern languages which have sprung from the ancient Geez, distinguished in modern philology by the conventional names of Tigriña and Tigré, both derived from the native Tigraj, which is applied to either indifferently. The Tigré, spoken by the half-nomadic races on the frontiers of Nubia and Sennaar is, at least among one tribe, the Habab, extremely like the parent speech; the Tigriña, on the other hand, is corrupt both in its sounds, its inflexions, and its vocabulary, and bears evidence more especially of Amharic influence. Tigré has been very partially investigated: Merx published, in 1868, a vocabulary and grammatical sketch; Munziger's vocabulary is printed in Dillmann's *Lexicon;* and a Tigré translation of the gospel of Luke by Kugler and Isenberg exists in manuscript. The Tigriña, or rather the Adoan dialect of the Tigriña, was treated pretty fully by Dr. Prætorius in his *Grammatik der Tigriña Sprache*, 1872, and he has since published, in the *Ztschrft. d. Deut. Morg. Ges.*, 1874, a paper on the two dialects of Hamâsên and Tanben, which differ considerably in vocabulary as well as in pronunciation, but are mutually intelligible. Another dialect mainly of Ethiopic character is spoken by the people of Harrar, who form a small Semitic enclave in the Hamitic population to the east of southern Abyssinia. Its peculiarities have been investigated by Burton, *First Footsteps in East Africa*, 1856, and by Prætorius in *Ztschr. d. Deut. Morg. Ges.*, 1869. The affinity of the Geez alphabet has given rise to no small discussion: Ludolf brought it into comparison with the Samaritan, De Lacy with the Greek and Coptic, and Lepsius with the Devanâgari, but in the opinion of most Semitic investigators, its Semitic origin has been proved by the discovery of the cognate Himyaritic alphabet or *musnad* (*cf.* Renan, *Hist. des Langues Sémitiques*, p. 308.)

The literature of the Ethiopian language, like that of Armenian, is almost exclusively Christian, and, indeed, with comparatively slight exceptions, theological or ecclesiastical. Only a few inscriptions have been preserved of the pre-Christian period, the most notable being those of Axum and Adulis, but it is not improbable that light will be obtained on the earlier times from the inscriptions of Southern Arabia, which are beginning to receive special attention. The language of the Axum inscriptions is the same as that of the Bible, and contains the Amharic element. The forms of the letters vary, and the older forms are liker the Himyaritic. Vowel signs are irregularly employed, and sometimes omitted, and the numeral notation is peculiar. The work which forms the standard of a classical style is the version of the Bible. According to native tradition it was made from the Arabic, either by the first bishop Frumentius (Abba Salâmâ) or by the "Nine Saints" of the 5th century; but internal evidence goes to prove that it was really derived from the Greek version in use in the

Alexandrian church. In the course of centuries it has undergone numberless alterations at the hands of copyists; but even its most corrupted condition leaves it clear that it must have been characterized by great fidelity to the Greek text. Among the MSS. of the Old Testament Professor Dillmann distinguishes three classes: the first, which seldom occurs, preserves in the main the original translation; the second, and most numerous, contains a text revised according to the Greek; and the third has been improved by comparison with the Hebrew. Besides the ordinary canonical books of the English Bible, and the ordinary apocryphal books, with the exception of the Maccabees, the Ethiopian canon includes a number of works of various interest and value, as the Kufale or Book of the Jubilees, the Book of Enoch, and the Ascension of Isaiah,—concerning which consult Apocalyptic Literature, vol. ii. The books of the Maccabees were either never translated or have been lost, but their place has been supplied by spurious productions of the same name. Several apocryphal books are also incorporated with the New Testament, which is usually reckoned to contain 35 altogether. It was printed in 2 vols. at Rome, 1548, in the London Polyglot, and in 1830 by the London Bible Society, under the editorship of Th. P. Platt. Dillmann published the Octateuch, Leipsic, 1853, the four books of the Kings, Leipsic, 1861–1871, Enoch, 1851, and the book of the Jubilees, 1859; and R. Lawrence published the *Ascensio Jesaiæ*, 1819, and the *Apocalypse of Ezra*, 1820, at Oxford. (*Cf.* Dillmann's article on the *Æthiopische Bibelübersetzung* in Herzog's *Real-Encyclopädie*, 2d edition, 1877.) Of the numerous works which rank as ecclesiastical authorities in the Ethiopian church, it is sufficient to mention the *Cyrillus*, which contains not only several dogmatic treatises of Cyril of Alexandria, but also similar productions of several others of the fathers; the *Synodus*, which includes, *inter alia*, the constitutions and statutes of the apostles, the canons of the councils of Ancyra, Neocæsarea, Sardis, Antioch, and Nicæa, an exposition of the Nicene creed, and an exposition of the Decalogue; the *Mafshafa kidân za egziena Iyasus*, or the Testament of our Lord Jesus (usually quoted as the Kidân), which treats of various ecclesiastical, liturgical, and eschatological matters; the *Genzat* or *Mafshafa Genzat*, and the *Mafshafa Kedr*, containing respectively the burial service and other sections of the ritual; the *Philexius*, a monastic treatise, probably translated into Ethiopic in the 14th century, and deriving its name from Philoxenus of Manbig. Among the poetic works are a collection of hymns in honor of the saints of the Ethiopian calendar, entitled *Erziabkhan nagza*, or "May God reign," and the *Organona Maryâm*, a eulogy of the Virgin in rhythmic prose. The MSS. of the *Marâšêt* or *Antiphonary* sometimes contain an interesting musical notation, which, according to native tradition, was introduced by a saint who lived in the 6th or 7th century. Certain works called *Savâsev* or guides are devoted to the illustration of the Ethiopian language, but they are very poor, and make no distinction between grammatical, lexicographical, and historico-scientific information, standing thus on the same level with such a work as Elyot's *Latin Dictionary*. The historical works, as for example those concerning Alexander of Macedon, are of little moment; and the real value of the lists of early kings of Ethiopia is still a matter of dispute. According to Prætorius, one of the most recent investigators (*Ztschr. d. Deut. Morg. Ges.*, 1870), all the statements made in Ethiopian literature about the earlier history of the country have been in the main derived from Arabic legends not earlier than the 14th century, and then reconstructed with the assistance of the king-lists, which alone have some degree of historic credibility. The European libraries which possess the richest collections of Ethiopian MSS. are the British Museum, the Bodleian, the Royal Library at Vienna, and the National Library at Paris. Ruppell's collections are preserved at Frankfort-on-the-Maine, and Krapff's at Tübingen and Würtemberg. The Bodleian catalogue was published by Dillmann, 1858; D'Abbadie's *Catalogue raisonné de manuscripts éthiopiens* appeared in 1859; and a list of the Magdala collection in the British Museum, consisting of upwards of 300 MSS., was contributed to the *Ztschr. d. Deut. Morg. Ges.*, 1870, by William Wright. Ewald gives a list of the Würtemberg MSS. in *Ztschr. für die Kunde des Morgenlandes*, 1843, and of the Tübingen MSS. in *Ztschr. d. Deut. Morg. Ges.*, 1847. Dorn had already made known the few works possessed by the St. Petersburg library, in the *Bull. de l'Acad.*, May and October, 1837. The Vienna collection is dealt with by Fr. Müller in *Ztschr. d. Deut. Morg. Ges.*, 1862. The first scholar who turned his attention to Ethiopian was Potkin of Cologne about 1513. A grammar and dictionary were published by Jacob Wemmers, a Carmelite of Antwerp, in 1638; and in 1661 appeared the first edition of the great lexicon by Job Ludolf, who, in the 1702 edition, prefixed a *Dissertatio de harmonia linguæ æth. cum. cet. orient.*, and was also the author of *Comment de Hist. æth.*

Modern works connected with the subject are:—Hupfeldt, *Exercitationes Æthiopicæ*, 1825; Dorn, *De psalterio æthiopico*, 1825; Tuch, *De Æthiop. linguæ sonorum proprietatibus quibusdam*, 1854, and *De æth. linguæ son. sibilantium usu*, 1854; Ewald, *Ueber des æthiop. Buch's Henokh Entstehung*, 1854; D'Abbadie, *Hermæ Pastor Ethiopice*, 1860; Schrader, *De linguæ Æthiopicæ indole*, 1860; Ceriani, *Monumenta sacra et profana e codicibus Bibl. Ambrosianæ*, Milan, 1861; Rodwell, *Æthiopic liturgies and prayers*, 1865; *Physiologus æthiopice*, 1877.

ETHNOGRAPHY AND ETHNOLOGY. I. *Definition.*—Ethnography embraces the descriptive details, and ethnology the rational exposition, of the human aggregates and organizations known as hordes, clans, tribes, and nations, especially in the earlier, the savage and barbarous, stages of their progress. Both belong to the general science of anthropology or the natural history of mankind, being related to it as parts to a whole. Ethnography and ethnology, indeed, run up into anthropology as anthropology does into zoology, and zoology into biology. No very sharp line can be drawn between these two sciences themselves, their differences being mainly those between the particular and the general, between the orderly collection of local facts, and the principles according to which they may be grouped and interpreted. Ethnographists deal with particular tribes, and with particular institutions and particular customs prevailing among the several peoples of the world, and especially among so-called savages. Ethnologists bring simultaneously under review superstitions, legends, customs, and institutions which, though scattered in distant regions of the earth, have some common basis or significance. Ethnography and ethnology run as easily one into another, as the two sections of general anthropology, viz., (1) *anthropology* proper, as expounded by anatomists and physiologists, who deal with the different races of man, their elements, modifications, and possible origin; and (2) *demography*, which, as constituted by the researches of Quételet and his friends and disciples, as Farr, Galton, Guillard, and Bertillon, treats of the statistics of health and disease, of the physical, intellectual, physiological, and economical aspects of births, marriages, and mortality.

Ethnography, ethnology, and anthropology are interwoven with philology, jurisprudence, archæology, geography, and the various branches of history. A fact may require to be investigated successively by linguists, anatomists, and mathematicians. In current language ethnography and ethnology are often used indiscriminately, but if a distinction is to be made between them, an instinctive perception teaches us to speak of ethnographic facts and ethnological theories, of ethnographic literature and ethnological science,—ethnology being related to ethnography as the wine to the grape.

II. *Division.*—Just as the lines which separate ethnology, anthropology, and history one from another are vaguely traced, so are the boundaries of the several provinces of ethnology themselves indefinite. We are obliged, for the sake of convenience, to draw up classifications, but the more rigorous we make them the more artificial they become. "Nature," as Lamarck has said, "recognizes neither kingdoms, nor classes, nor orders, nor genera, nor sub-genera; nature recognizes nothing but individuals." The older sciences may be tabulated to a degree which the younger sciences cannot allow, and ethnology is one of the youngest of all,—its existence, even its name, not dating further back than the present generation. Ethnologists are pioneers in a new field of inquiry,—squatters in the Far West of learning. Intent on opening the first paths through the dark forest of prehistoric times, on driving the first plough through these virgin prairies, they erect no structures which pretend to more than a provisional character. They throw up now a log cabin, and now a wooden shanty, leaving to their successors the work of building substantial houses of brick, and in the far future stately edifices of enduring marble.

At first sight it might appear convenient to divide ethnology into two great branches:—(1) *historic ethnology*, comprising researches into the origin, the filiation, the customs and institutions of wild and barbarian tribes still existing, or of whom we have authentic records; (2) *prehistoric ethnology*, comprising similar researches into the early condition of man, but founded necessarily on deductions, and not on positive testimony. But the fitness and the simplicity of this division are more apparent than real. The two sections as thus indicated cannot be treated apart, because so few or incomplete are the vestiges of prehistoric man that they cannot furnish a basis for sound theories unless these remains are studied in the light of the knowledge which we possess of tribes existing in the non-civilized state, and who thus form the connecting link between historic and prehistoric man. Being a part of natural history, anthropology deals principally with the question of the several races, their anatomy, physiology, and pathology. It seeks to determine which are the permanent varieties, by the crania, by the facial features, by the stature and proportion of the body, by the microscopic structure of the hair, by the color of the skin. It analyzes the great problems of evolution. It assigns to food, to climate, to what the French call the *milieu*, and the Americans "the surroundings,"—the share which each has had in producing or fostering the variations of human types. Ethnography does not discuss anew the solutions presented by anthropology, but accepts them as generally true, and observes if they fit and work satisfactorily in its department. The task, thus limited in order to secure its better execution, is still a gigantic one. Human development branches out into a multitude of ramifications, which may be brought under the following heads:

1. Material Development.
2. Family "
3. Social "
4. Intellectual Development.
5. Religious "
6. Moral "

III. *Method.*—Astronomy starts from the principle that the laws of mathematics, and those of light and matter are universal,—that they are true not only on the earth but throughout the universe. Ethnology takes its stand on the assumption that the laws of intelligence have always been what they are, and have always operated as they do now, that man has progressed from the simple to the complex, from the particular to the general. This assumption does not interfere with the discussion which the anthropologists carry on respecting monogeny or polygeny,—that is to say, the common or multiplex origin of the different races which inhabit the earth, nor does it affirm that the progress has been always continuous and well marked. It recognizes the fact that some races may have been stationary and some may even have retrograded. It postulates simply that mankind, whatever be its origin, is, or has become, a mass practically homogeneous, more uniform than diverse. The wide differences between civilized and uncivilized man are now admitted to be only differences in degree,—actual civilization being the adult age, and savagery the infancy of mankind. "The conditions and habits of existing savages," says Sir John Lubbock, "resemble in many ways those of our own ancestors at a period now long gone by; they illustrate the earlier mental stages through which the human race has passed." To the casual observer, savages seem to be, as to Dr. Johnson, all alike, and in fact they are so in comparison with ourselves; but to the close observer who compares savages with savages, they are easily distinguishable. Although contemporaries, they are separated by differences in culture so great that it would seem the work of centuries for the more backward to attain the state already reached by the more advanced. Great, indeed, are the facilities which ethnology confers on the historian who may, for example, explain the condition of the Israelites under the Judges by that of the Maories of New Zealand, as they were almost within the present generation, or may compare the earliest Aryan races with the Malay-Indian populations of to-day. By its aid the philosopher may trace an institution through all countries and in every period, accumulating illustrations of its progressive stages, and piecing them together in their natural sequence like the scattered bones of an extinct animal. Uncivilized countries are for us a standing exhibition of prehistoric matters, museums where we find duplicates of objects which were thought to be lost or which were forgotten; each of them is a Pompeii, exhumed from beneath the rubbish of ages. To study wild tribes is, as it were, to discover in the forests of Central America an ancient city, not crumbling and desolate, but still inhabited by a race preserving the old Maya habits and manners. The laying bare of all these scientific riches gave the impulse to which we owe ethnology. It does not require much reflection to understand that the principle just developed is an instance of the great law of evolution. According to the naturalist of the modern school, evolution has transformed successively the animal genera; according to the anthropologist, it has transformed the races of man; and, according to the ethnologist, it has transformed human thought. It must be confessed that evolution has yet opponents who contend that history records, not progress, but degeneration from a state of innocence and bliss, from an age of gold or Saturnian cycle. This doctrine, borne out by the unanimous testimony of all tradition, was assumed at one time to be beyond dispute, and had nearly become an article of faith. But in recent times it has not remained unchallenged. In answer to its assailants, the theory of degeneration has, within this century, been reasserted with great ingenuity and vehemence by ultramontane writers, such as De Maistre and De Bonald, and in our own country it has been more recently defended by Whately with characteristic vigor. But an effective reply has been given by such writers as Lubbock and Tylor, especially the latter, who concludes an exhaustive discussion by these words, to which most ethnologists will subscribe:—

> "We may fancy ourselves looking on civilization as in personal figure she traverses the world; we see her lingering or resting by the way, and often deviating into paths that bring her toiling back to where she had passed by long ago: but, direct or devious, her path lies forward; and if now and then she tries a few backward steps, her walk soon falls into a helpless stumbling. It is not according to her nature; her feet were not made to plant uncertain steps behind her; for both in her forward view and in her onward gait she is of only human type."—*Early Culture*, ii.

To the facts and reasonings adduced by the naturalists Mr. Herbert Spencer adds the weight of speculative argument:—"Each organism," he says, "exhibited within a short space of time a series of changes which, when supposed to occupy a period indefinitely great, and to go on in various ways instead of one way, gives us a tolerably clear conception of organic evolution in general. The whole exhibits one grand scheme of progression." These words are the substance of the whole philosophy of evolution, which, sketched out by Maupertuis, Lamarck, and Goethe, reasserted and victoriously demonstrated by Darwin and Wallace, and taken up by Huxley, Virchow, Quatrefages, Broca, and Haeckel, now underlies all ethnological research.

In the view of its supporters, evolution has not only in past ages differentiated genera and species, but is at work to-day in transforming the actual types. Here may be the place to advert to the great law, of which Von Baer and Agassiz were the most thorough and successful exponents, namely, "that the development of the individual is an epitome of that of the species." The human embryo, for example, passes rapidly through all the principal phases, in one or other of which whole series of inferior animals stay permanently, in such a manner that every new generation repeats in an abridged manner those that have gone before. Of the many corollaries which follow from this theory, the most important seems to be that, however much some groups of animals may differ from each other in structure and habits, they must have descended from the same parent form, if they are found to pass through similar embryonic stages. This is *heredity*. Ethnologists, again, have not been slow in borrowing this law from anatomists. The embryo going over the same organic form as the species, they argue that the child too must repeat the intellectual developments of past mankind. Parents, and not only the observers among them, had already reversed the opinion of the philosophers that savages are children by saying that children are savages. The remarkable similarity between their ideas, language, habits, and character, though generally admitted, had been regarded merely as a curious accident; but coincidences of such vast magnitude are not to be considered as merely accidental. Everybody knows, and the fact is as important as it is obvious, how boys delight in romping, running, leaping, boating, swimming, and all outdoor exercises, and how their favorite heroes are the Red

Rover, Robin Hood in the forest green, Robinson Crusoe in the solitude of his island home, where he had to begin all anew.

Peculiar instances of the general law of inheritance have been called *atavism.* It occurs often that one individual is the exact countertype of his grandfather, or some more remote ancestor. By this law, still a very obscure one, ethnologists explain how men are occasionally met with who live in the midst of our civilization as mere savages. The passion manifested by many people for hunting and fishing as a sport, for a tramping roving life, the frequent falling or relapse of French settlers in Canada (the Bois brûlés) into Indian habits, are supposed to be manifestations of atavism. But our stiff and rigid civilization is averse to those old-fashioned individuals, who roam about, living from hand to mouth; the existing system of law can scarcely be brought to distinguish them from criminals. Moralists attribute to atavism a large number of offences which lawyers attribute to guilty dispositions. Now-a-days more than one Boadicea emerges into a brief celebrity upon being sentenced to hard labor in the house of correction; more than one Cassivellaunus has been severely flogged and sent to penal servitude. Mr. Dugdale, an industrious statistician of New York, has traced to its common ancestor a family, the Jukes, consisting of 1200 people, of which the majority are paupers, thieves, or prostitutes, in a greater or less degree, and who are computed to have cost the state in prison maintenance, almshouse relief, etc., something like £260,000. The ancestor was a descendant of the early Dutch settlers, and lived much as backwoodsmen do now upon the Indian frontiers. He is described as a "hunter and fisherman, a hard drinker, jovial and companionable, averse to steady toil, working hard by spells and idling by turns, becoming blind in his old age, and his blindness has been entailed upon his children and grandchildren."

It is not, however, owing to atavism, but to the mere continuance of an old order of things, that so many of our ill-educated classes, shepherds, agricultural laborers, and even factory hands, are as little developed, and live a life as little intellectual as savages. Latent in our small hamlets and large cities there is more savagery than many reformers are aware of, and it needs but little experience to discover something of the old barbarity lurking still in minds and hearts under a thin veil of civilization.

Atavism is a word applied to persons; *survival,* an expressive word for which we are indebted to Tylor, has a similar meaning, but is applied to things. Survivals are habits, ideas, or expressions which are senseless and perfectly inexplicable by the light of our present modes of life and thought, but can be explained by reference to similar customs or prejudices which are still to be found among distant tribes, or which are mentioned by ancient writers. The word *survival* corresponds exactly to the Latin word *superstition,* meaning the remainder or residue of bygone ages. But as the use of the word superstition is practically restricted to matters pertaining to religion and magic, a more general word had to be coined. "Survivals," says Tylor, "are milestones on the way of culture." They are intellectual fossils. Just as spear-heads and fragments of ancient pottery are disinterred by the plough in the midst of our fields, so survivals may be picked out in our daily conversation, in our habits and manners, but it requires a trained intelligence to detect them. Their original meaning has been lost, and they have been modified and distorted to serve modern purposes. Survivals may be compared to those muscles or pieces of bone which are retained in the bodies of animals and even in the human frame, as relics of a former construction. But sooner or later they will fall to the ground. Nature closely husbands her means; she may keep for a while forms that are apparently useless; it seems that she has forgotten them, or that she intends to fall back on them in case of failure; but when the new type is firmly settled, everything that is not serviceable disappears.

The scientific exploration of caverns with a view to discovering the remains of ancient men and beasts, as Pengelly has described it in the case of the Kent Cave, may serve as a model to ethnographers. The explorers did not leave an inch of soil untouched; all the mound was dug out yard by yard, and carefully sifted; nothing was taken up, nothing thrown away without good reason; the objects collected were labelled with care, and even the nature and the condition of the refuse recorded. So the main work of the ethnographer consists in scooping the historic or the prehistoric soil, in picking up everything that has lived, or that has been touched by living hands, and not rejecting as valueless anything as long as he is not perfectly cognizant of its nature. Thus he finds precious things and valuable information where the ignorant sees but heaps of offal and scourings. And when he travels, especially in semi-civilized countries, there is no limit to the things he may look and inquire after; the less the people are civilized, the richer the harvest he may gather in. One investigator prefers to study the people themselves, another their institutions. But whatever be the study, the first rule will always be to observe the facts with unprejudiced eyes; to draw a deep line of demarcation between them and all mere conjectures. Besides, all explanations have to be called in question, even those which seem sensible and judicious; the student is in duty bound to distrust every theory and interpretation, especially his own glosses and commentaries. Rushing to conclusions is a fault into which beginners are sure to fall. The unscientific mind resembles the child in many respects, and in none more than this: it is impatient and cannot bear suspense. Ready acquiescence in the assertion of others is dangerous, and easy conviction in one's own ideas is the worst bane to science.

One single fact well observed, well authenticated, is a positive gain, and may turn out to be of the highest value in future studies. But a single fact proves too much or too little; as long as it stands alone, nobody can know whether it demonstrates a general law, or only an exception, as we see by the controversies still held on the famous skull of Neanderthal. Laws are obtained by grouping analogous facts in series. In nature, as in history, a series may be termed the development of an idea. Therefore, when the ethnographer does not restrict himself to the simple description of a single subject, of a single locality, of a single custom, he will have to search for analogous facts, that he may give the reader a scale of comparison. For he would expose himself and his readers to gross errors if he were to conclude from a single trait to the whole institution, or from a single institution to the whole national organization. Such primitive populations as the Aleutians or the Todas it would be easy to represent as living either in a moral paradise or in a moral hell, according as one chose to regard only the attractive or only the repulsive side of their character. A fine ethnographical portrait, which is an abstract representation, will be always difficult to draw. In the sketch of that collective individual, a nation, the features must be impressed with the many lines and furrows which the wear and tear of existence have left on the original. In describing an institution, which is a collective fact, the numerous and contradictory feelings must be indicated which it stirred up in the many minds and hearts on which it acted, and which reacted on it. But masters only know how to blend light and shade—how with some few colors to express a multitude of things.

Ethnology, having entered on the scientific stage of development, requires to be treated as a science. The fields of anthropology and ethnology are no longer the tilting-yard for fancies against opinions, for hypotheses against guesses; they are now the place where facts well authenticated are stored up and gathered into orderly groups. Ethnology has become a science of observation, a branch of natural history. It was born the last of all sciences, not because it is the most difficult, but, on the contrary, because, being easy enough, people have dealt with it too lightly. Everybody thought himself able to judge, and his sentences expressed his biases or dislikes. Now, ethnology requires of its adepts that they be as unprejudiced as mathematicians, that they discard all preconceived judgments as much as do the chemists and physicists. Ethnographers must be exact observers and faithful recorders. Science and virtue alike begin and prosper by the same means—by sincerity and by effort.

IV. *Material Development.*—Any inquiry into the material progress of man bears upon a multitude of details. Briefly stated, the most important are Food, its nature and its preparation; Weapons, Tools, and Implements; Shelter and Clothing; Domestic and Public Fires; Barter and Trade.

Food.—Man has been defined as a digestive tube. He is happily something else as soon as his most imperious physical wants are satisfied, but it must be confessed that, until the cravings of his hunger or thirst are allayed, he is little better than a ravenous brute. For the statesman and the economist there is scarcely any question of more gravity than that of subsistence, even in the face of our enormous accumulation of wealth, in spite of our gigantic means of communication. There are four great phases through which nations pass, or have passed,—hunting and fishing, sheep and cattle tending, agriculture, and industry; and these are nothing else than a succession of improvements in the means of raising food. All the results of manifold culture converge towards a grand total,—more food for more men, better food for every man, and consequently lives longer and more numerous. A simple calculation shows how much modern industry increases the amount of disposable food. From the United States census, showing the extent of land occupied by the Redskins in 1825, it was calculated that the hunting tribes, although they raised some maize, required 1·75 square miles per head. At that rate, all Europe, including Russia, could feed two millions of Indians and no more; but, thanks to its agriculture and to its industry, it supports three hundred millions of inhabitants. It would be hazardous to estimate how many more Indians the North American prairies might feed, if those Indians had taken to bison breeding instead of bison hunting. According as the chief produce of the herd is to be milk or meat, the calculations would vary by large amounts. Nor ought the yield of our improved breeds to be taken as the measure. But, to proceed, it is reckoned that an area under wheat affords from ten to twelve times more human food than it would give under grass for cattle or sheep. That ratio, ten or twelve to one, may express in human lives the progress which was realized when husbandmen succeeded to nomad communities. With the introduction of steam as our great mechanical agent, we are entering the period of large cities. Human anthills of one million souls and more exist already in many parts of the world; they increase constantly both in absolute numbers and relatively to the population at large. It is already necessary that the supply of food to these immense agglomerations of "digestive tubes" be as regular as clockwork.

For the chief information we have on the subject of human food in prehistoric times, we are indebted to Professor Rütimeyer, who examined the fauna of the lake dwellings in Switzerland, and to Steenstrup and Thomsen, who dug up the shell mounds of Denmark. They have displayed in their researches an amount of science and sagacity which is an honor to our century.

The quality of food is calculated to exert a great influence upon the temperament, the health, the vigor, and the intelligence of men. There is thus some truth in Buckle's statement that the history of the most civilized nations may be explained by the chemical constituents of their food; but until the action of aliments on bodily and intellectual organisms is better known, the discussion would be premature. Besides, the subject belongs to anthropology, and if ethnologists mooted it, they would trespass upon their neighbors' preserves. Were primitive men a set of cannibals? Plausible reasons may be given for and against such a view. As men can feed on men but exceptionally, the question would be better discussed in the chapters relating to religious sacrifices and to the progress of morality and intelligence.

Weapons, Tools, and Implements.—Ethnology centres in this study, and by far the greatest number of ethnologists have made it the chief subject of their researches. They go everywhere, beating about all corners, looking for potsherds, bones, teeth, chirts, nephrites, flints, and everywhere their search is more or less successful. *Ex ungue leonem* is their motto. As the tool, so the work and so the workman; as the arrow-point, so the archer. And they are right. Man is a tool-using—or, as Franklin defined him, a tool-making—animal. These weapons, these implements were subservient to the tyrannic necessity of obtaining food. The better the weapons, the more regular the supply of nourishment, and as the food changed, the tools had to be changed. Wood, bones, and rough stones were first used, then polished stones, afterwards bronze, and lastly iron,—each marking a new era. Strong doubts, however, begin to be entertained in many quarters about the separation in two periods each of the stone and of the metallurgic ages: it is objected, first, that polished stones were used as articles of luxury, or where flints could not be had, and, secondly, that the finding of bronze implements much older than any of iron does not prove that bronze was invented before iron, because bronze keeps in a tolerable state of preservation when iron, which oxidizes readily, has long disappeared; and, moreover, it is asserted by technologists that iron or steel tools are indispensable in the fabrication of bronze. Be that as it may, every invention was more than a simple addition to the old stock; it was an advance in quality and variety as much as in quantity; it marked a new progress in intelligence. Tylor says—

> "The ethnographer's business is to classify such details with a view to making out their distribution in geography and history, and the relations which exist among them. To the ethnographer, the bow and arrow is a species, the habit of flattening children's skulls is a species, the practice of reckoning numbers by ten is a species. The geographical distribution of these things, and their transmission from region to region, have to be studied as the naturalist studies the geography of his botanical and zoological species. Just as certain plants and animals are peculiar to certain districts, so it is with such instruments as the Australian boomerang, the Polynesian stick-and-groove for fire-making, the tiny bow and arrow used as a lancet or phleme by tribes about the Isthmus of Panama; and in like manner with many an art, myth, or custom found isolated in a peculiar field. Just as the catalogue of all the species of plants and animals of a district represents its flora and fauna, so the list of all the items of the general life of a people represents that whole which we call its culture. And just as distant regions so often produce vegetables and animals which are analogous, though by no means identical, so it is with the details of the civilization of their inhabitants. How good a working analogy there really is between the diffusion of plants and animals and the diffusion of civilization comes well into view when we notice how far the same causes have produced both at once. In district after district, the same causes which have introduced the cultivated plants and domesticated animals of civilization have brought in with them a corresponding art and knowledge. The course of events which carried horses and wheat to America carried with them the use of the gun and the iron hatchet, while in return the Old World received not only maize, potatoes, and turkeys, but the habit of smoking and the sailor's hammock."

House and Shelter.—Previous to the recent scientific movement to which we owe ethnology under its present form, architects had already divined and applied to their art ethnological principles. They had understood that the most superb temples and palaces, the most splendid monuments, when they have a national character, reproduce on a large scale the modest abodes of the country people. A greater care is bestowed on the construction of a princely hall, its materials are more costly, the proportions more stately; but in most cases it is a poor man's cottage magnified. So a church may be but the enlargement of a sepulchre. If the homesteads of the earlier inhabitants were caves or some piled-up slabs, if they were tents or log cabins, the primitive physiognomy will be still detected in the disposition of the magnificent buildings, and even in the costly furniture. For one sees in the Egyptian temples that their columns were imitations of Nile reeds tied in a bundle, that their walls were an imitation of plaited mats. What is called the architectural style is the character of the nation and of the epoch expressed in wood, stone, or brick.

Fire.—After some discussion, it appears now to be the general belief that there has not been within historical times any race of men ignorant of fire. There is certainly a wide chasm between civilized and uncivilized men, but none so deep as would imply the absence of fire, the use of fire being the great practical distinction between man and brute. We have to avoid the double danger of supposing uncivilized tribes to be either too intelligent or too stupid. Indeed, if it had not been for fire, mankind could not possibly have become what it is. It is a theory amongst architects, to whose relations towards ethnology we have just adverted, that the first buildings of men, inhabitants of caves, holes, or trees, were not dwellings for themselves, but simple hearth-places protected by reed walls and some thatching against wind and rain. They believe that on this model of a prytaneum, or abode of the fire-god, the abode of his priest, and then of the kings and the chiefs of noble families, were successively erected, and that it is only in later times that all families obtained a fire-place of their own.

We have spoken of tools and weapons; their history and that of modern industry are inseparable from the history of fire. Everywhere the stone celts and arrows were alleged imitations of thunderbolts, and are still believed by many villagers to have been once hurled down from the skies. Fire is mixed up with whatever men had to tell about things of the earth, of heaven, or of hell. Fire-lore is a science by itself.

Commerce and Industry.—Slaves have been, perhaps, the first commodity purchased by the pastoral from the hunting and warlike tribes. Lindenschmidt and Peschel have reacted against the current belief that the tools and implements of bronze and steel had been manufactured in the countries where they have been found. They note that commerce already existed in the earliest ages of which we have any notice. It must have been by barter that the cave dwellers of Perigord, in the reindeer period, obtained rock crystals, Atlantic shells, and the horns of the Polish saiga antelope. The Phœnicians, and their descendants the Carthaginians, were attracted to and retained in Spain by the quarrying of silver ore. Tin has promoted civilization even more than silver, for without tin bronze cannot be produced. The Celts may have had some skill in metallurgy, as they taught the Romans the art of tinning utensils, and were taught by them the fabrication of coins. Important mines were worked in the Scilly Islands and in Cornwall. If Carthaginian or Phœnician vessels ever reached the west coast of France or entered the Channel, they must have been in quest of tin, and probably too of *débouchés* for their manufactured bronze. At all events there was intercourse between the northern countries and the Mediterranean by land. That such land traffic existed is proved by the early foundation and prosperity of Marseilles; moreover, the lumps of tin ore which have been found among the Swiss relics of the bronze age must have reached Helvetia by inland commerce. It was owing to the presence of tin that the Celts of Gaul and Britain were of far higher social development than the Teutons of the time of Cæsar. The possession of an article of export so indispensable, and the fact that tin was in such great request in the age of bronze, was in itself the means of promoting civilization, for commerce at a very early period brought the Britons into contact with the Mediterranean nations, and especially with the Etruscans, the great bronzesmiths of antiquity. The inhabitants of the coast of the North Sea, and still more of the Baltic, possessed an analogous property in amber. It is doubtless to this coveted substance that the numerous "finds" on the shores of the Baltic are due, where Greek and Roman coins, as well as bronze instruments, were brought, some by way of the Euxine and Pannonia, along the Danube, some along the Rhone and the Rhine, and even some few across the huge barrier of the Alps.

The obsidian blades which are occasionally met with in ancient graves to the east of the Mississippi must have reached by barter the places where they are now discovered. We must not imagine that the Redskins had no intercourse but that of murderous feuds. Merchant boats passed along the great rivers, and transit-dues were taken by the chiefs. In South America, curare, the arrow-poison, the preparation of which was understood only by a few hordes, formed a valuable article of commerce among the Indians of the Amazon, so that people living near the Napo were obliged to make canoe voyages of three months' duration in order to procure it. Even where bands of hawkers and peddlers did not wander through the country, goods, such as nephrit hatchets, salt, curious shells, coloring stuffs, were bartered between horde and horde; and thus a system of intercourse might have extended throughout an entire quarter of the world. English wares, deposited at Mombas on the eastern side of South Africa, have been recognized at Mogador, on the west coast of Northern Africa. From these circumstances we assume that commerce has existed in remote ages and among most inhabitants of the world. And we must not lose sight of the fact that if we find trade and emporiums in one place, some corresponding industries and manufactures must exist elsewhere in connection with them.

V. *Family Development.*—To say that of all institutions the family is the oldest and most sacred, that from it all social rights and duties are derived, like branches from the parent stem, would be considered a truism. Nothing looks more plausible than the universal traditions, apparently well founded on historical records, according to which the founder of the nation, the ancestor, as he is called, had sons, who founded families, which increasing at every generation, became so many tribes, which coalesced as time went on. Historians and moralists have not been slow to credit the poets whose idyls described in glorious colors these primitive families. It was the belief that, notwithstanding the expulsion of man from paradise, and the murder of Abel by his brother Cain, the progenies of our first parents led a gladsome life, scarcely less innocent than it was when lambs and lions frolicked together on the banks of the Gihon and the Pison. Directly after the deluge the so-called patriarchal family is thought to have arisen. Perhaps even then it was a little tainted with polygamy and some other minor defects, but on the whole it was a model of virtue, worthy to be set as an example to a degenerate posterity. Modern research flatly contradicts this common-place romance, denies these self-evident propositions which have become historical axioms. Science is no longer of opinion that tribes and nations have been evolved from the family; on the contrary, it holds that the family has been evolved from tribes and hordes. It is not denied that the first step in the path of material and moral progress began with the rearing of a family, and that family cares have been the most powerful agents of civilization, but it is denied that the family has existed in a perfect state from the beginning. The family had to grow like everything else. As we see it now, it is an institution of a comparatively recent date.

In the same manner the belief, conscious or unconscious, has prevailed in most minds that monogamy was the first law of marriage, and that polygamy and polyandry have been wilful departures from a known rule. The reverse appears now to be the fact. In a book which was published as far back as 1861 Professor Bachofen of Basel propounded a theory, deduced from a careful study of classical literature, that true marriage, unknown to the hunting, the fishing, and the nomadic tribes, arose with the spreading of agriculture, the husbandman wedding the wife at the same time that he wedded the soil. Previous to "husbandry" in both senses of the word, previous to any regulation in the matter, the females and the children, he contends, were the common property of all the males of the tribe. In some legends this state of things was symbolized by the spontaneous vegetation of the marshes, rushes and wild asparagus. But the woman, spoil of the victors, passed or knocked about from man to man, and even from tribe to tribe, yearned after a better regulated state of things. Under her influence, the rudiments of the family grew into shape. Paternity was an idea which did not and could not have a place in such societies. A child had a hundred fathers or none, but he had one mother; he knew the breasts which had given him suck. In this state of human relations, descent was traced exclusively through mothers. The first kinship was between the offspring of a common female ancestor. To trace descent through the male is an idea of far later date. By this discovery (for it deserves to be ranked as a discovery) a flood of light was thrown on a whole region of the obscure past. It is assumed that under the influence of the then recent idea of motherhood diverse religions arose, all having as principle the worship of Mother Earth, Demeter. And starting from the supposition that religions have been always the expression of the deepest thought and the loftiest aspirations of their worshippers, that practice was the exact counterpart of philosophy, Professor Bachofen inferred that, the Divine Mother having been recognized as the fountain of existence and the source of all right, the human mother was likewise the fountain of authority; and that in some places, and for a certain period at least, woman as such had exercised political power, and had enjoyed a certain degree of social supremacy,—a startling conclusion, which the stories and traditions respecting Oriental queens did not sufficiently justify.

In originating the theory of *gynæcocracy* so-called, the limit of valid deduction had been overstepped, but the great law of maternal filiation has proved sound. Meanwhile, in his *Essay on Primitive Marriage*, M'Lennan had come to the same conclusions as the author of *Mutterrecht*, about the system of kinship through females only. He made the system clear, not by abstract and far-fetched considerations, or on scanty testimony transmitted by Herodotus, Hesiod, or Æschylus, but by the unmistakable instances which ethnography most abundantly supplies. It is now admitted as a fact that maternal kinship was anterior to the paternal, or, as Sir John Lubbock puts it, "children were not in the earliest times regarded as related equally to their father and their mother; but the natural progress of ideas is, first, that a child is related to his tribe generally; secondly, to his mother, and not to his father; thirdly, to his father, and not to his mother; lastly, and lastly only, that he is related to both." M'Lennan had been led to formulate the principle by a careful study of that old Roman legend, the Rape of the Sabines. He demonstrated that the legend was in accordance, not only with the practice still prevalent in many savage countries of capturing wives by violence, but with the sham fights and mock scuffles which, even in our days and in Europe, take place between the bridegroom's party, pretending to carry off the bride, and the bride's party, pretending to ward off the bridegroom's attack. He showed that the symbol implied something more than the mere lawlessness of savages, and proved the fact that at one time wives were systematically obtained by theft or force. And as real capture could not have been practised by peaceful neighbors in the midst of the same community, it was necessary to infer that wives were captured from other tribes, whence the distinction between *exogamous* tribes, marrying outside the pale of their community, and *endogamous* tribes, marrying within it. He supposes that the origin of exogamy is to be connected with the practice in early times of female infanticide, which, rendering women scarce, led at once to polyandry within the tribe, and the capturing of women from without. To tribes surrounded with enemies, struggling against the difficulties of existence, sons were a source of strength, both for defence and in the quest for food; daughters a source of weakness,—they ate and did not hunt. They weakened their mothers when young, and when grown up were a temptation to surrounding tribes. Hence the cruel custom which made the primitive human hordes prey upon one another for wives.

Tylor, who has also called attention to exogamy, regards it as mainly due, not to infanticide, but to the beneficial effect of marrying out-and-out, and to the physiological evils of marrying in-and-in. This theory is favored by established maxims, breeding in-and-in being perhaps held by public opinion as more noxious to the human species than professional breeders think it for animal stock. As an exogamous tribe increased and enlarged its territory, it may have become endogamous for practical reasons. Sir John Lubbock suggests another motive. "Endogamy seems to have arisen from a feeling of race pride, and a disdain of surrounding tribes, which were either really or presumably in a lower condition." Sir Henry Maine is very suggestive:—"The barbarous Aryan is not generally monogamous, but exogamous. He has a most prodigious table of prohibited degrees. The Mussulman, however, is not only polygamous, but endogamous; his law permits comparatively near relatives to intermarry. The comparative liberty of intermarriage is a part of the secret of Mohametanism's success in India."

Lewis Morgan, an American who had studied by personal intercourse the organization of the family among the Seneca Indians, into whose tribe he was adopted, says, in his *Ancient Society*, that exogamy and endogamy are not as antagonistic and contradictory to each other as they are supposed to be. According to him, the community at large is often practically endogamous, while the *gentes*, or set of families, which constitute it are rigorously exogamous. The lineage is in most cases through descent in the female line, and the males are obliged to marry into other gentes.

Family institutions are in themselves an interesting object of study, and they have besides a wide practical bearing, as they are everywhere inseparably connected with the rules of property and inheritance. They may be conveniently discussed under the following heads:—

Marriages communal and free to all members of the tribe—Hetærism or Promiscuity—Woman Capture—Female Infanticide—Marriages communal, but restricted to certain sets of persons—Endogamy—Exogamy—Adelphogamy—Levirate—Polygamy—Polyandry—Marriages by Pairs—Monogamy—Courtships—Bridals—Marriage by trial—Nuptial customs—Divorce—Widowhood—Re-marriage—Birth Ceremonies—The *Couvade* (a custom which was held to be the quintessence of absurdity, until it was shown to be a symbol by which the father acknowledged the child, and especially the son, to be his)—Ceremonies observed at the giving of the name, at the cutting of the first tooth, and upon arrival at puberty or nubility—Old age and infirmities—Parents killed by their children through filial piety, or from poverty—Funeral rites, few of which, if any, can be explained unless they are looked at in the light of religious ceremonies.

VI. *Social Development.*—Sociology narrates how men became grouped in political communities, how they constituted authority and property, how they originated castes and guilds, and by degrees separated into high and low, rich and poor. Of all the fields in ethnology, none is at present cultivated with more care and intelligence than that which deals with the history of society, and none perhaps with a greater prospect of fruitful results.

Grouping in Hordes, Tribes, or Nations.—Man is a gregarious animal. Society develops intelligence, comfort, the sentiments of justice and equality, of fraternity, goodwill, and cheerfulness to a degree which would have been unattainable in a severe and prolonged solitude. The first hordes were scattered over vast areas, and were each very small. It is probable that they were recruited not only from within by births, but from without by capture of women and children, and by the voluntary or forced accession of their neighbors to their ranks. We draw a distinction between the human horde, which we hold to be superior only in degree to a herd of brutes, and the tribe, in which we recognize the first buddings of culture. The love of the mother for the young is an impulse to intelligence and devotion among all higher animals. The certainty of parturition at a period fixed for every species induces precaution and forethought. The rudiments of true humanity we conjecture therefore to have been the acknowledgment of motherhood by the tribe, and the first regular provision for the care of the expected infant. As it has been said already, the family had its origin in the gathering of children round their mother. These children became to one another brothers and sisters by the remembrance of the care they had enjoyed in common. They kept together; so did their children and their children's children; and the *gens* took shape and life.

Probably the original horde was by degrees remodelled into tribes by the gentes which had taken birth in it. The word gens, equivalent to clan, sept, or totem, being the best known of all, may be used in a general sense to denote all kindred institutions. The tribe became an organization of gentes. An Indian tribe, according to Lewis Morgan, is composed of several gentes, developed from two or more, all the members of which are intermingled by marriage, and all of whom speak the same dialect. To a stranger the tribe is visible, and not the gens. It is highly convenient for a tribe to contain at least two gentes, which, if they choose to intermarry, would find wives at their own door. A fundamental law of the gens prohibited marriage between gentiles, or members of the same gens. For most communities were deeply averse to consanguineous marriages, which they branded with the infamous name of incest, though some others held them to be highly commendable. The original rule was that all descendants by the same mother were to be regarded as brothers and sisters, and they were soon forbidden to contract matrimonial unions. As there was no relationship by the father's side, the patriarch Abraham could in all propriety take his sister, or rather his half-sister, as a wife. And such a tribe, consisting of two gentes only, intermarrying constantly, might be composed of first cousins only, and be strictly endogamous nevertheless.

Further rights and duties of the gentiles were the reciprocal obligations of help, defence, and redress of injuries against any one from without. They had the same religious rites, and a common burial place. The archaic gens inherited the property of its members, as they were taken away by death, and redistributed it every year, or at stated periods. All children of earth return by death to her bosom, and all the gentiles were brought to rest in a common burial place. The gens was primarily a great motherhood, and the gentiles, all of them, were supposed to be brothers and sisters, and to live in their mother's home.

As in the course of time the gentes increased, they segregated to a certain extent, but maintained their association for certain common objects; the enlarged association was called a *phratria* or brotherhood. Each of the four tribes of the Athenians was organized in three phratrias, each composed of thirty gentes. The Roman *curia* was the analogue of the Grecian and the Iroquois phratrias.

In the normal course of events the tribes increased and segregated as the gentes had formerly done. And "as the gentes had recoalesced in phratrias, so did the tribes reunite in confederacies." Where one Indian tribe had divided into several, and the subdivisions occupied independent but adjacent territories, the confederacy reintegrated them in a higher organization, on the basis of the common gentes which they possessed, and of the affiliated dialects which they spoke. The confederacy had the gentes for its basis, and the mother language as the measure of its extent. Its formation required the highest skill. The Iroquois ascribed the origin of theirs to divine inspiration; they considered it to be "the masterpiece of wisdom." To bring many tribes together, to conciliate the conflicting interests in a superior organization, and make it work, requires an intelligence much superior to that which is required for gaining victories in the battlefield. Therefore confederacies have been always rare achievements. The common course of events has been rather that tribes have become nations, not by peaceful and voluntary aggregation, but by the bloody work of war and conquest, by constant encroachments on the territory of neighbors, by killing part of them, and enslaving the rest.

Authority.—When not actually engaged in a war or in a hunting expedition, wild tribes are often without recognized chiefs. In case of need, in dangerous emergencies, natural superiority soon asserts itself, and the boldest, strongest, most intelligent, or most experienced steps forward as leader. With the children of nature authority is of a more transient and less definite character than with us. Their aggregations are, as a rule, very small. In order to understand the most ancient condition of human society, says Sir Henry Maine, all distances must be reduced, and we must look at mankind, so to speak, through the wrong end of the historical telescope. Many anthropologists are of opinion that civilization has increased the differences in the anatomy of man and woman, in the stature of giants and dwarfs. There is stronger evidence that it has increased intellectual differences. The oscillations on either side of the average line of learning and intellect are widest in our populous and complicated communities, where the talented are more talented, and the stupid more stupid than elsewhere. In small bodies politic there is not the same necessity for strict discipline as in the large ones. And the larger they grow, *totis paribus*, the more despotic they become. History has shown it to be the case with all great monarchies, which in times ancient and modern have been synonymous with despotisms. When conquering Rome overstepped the limits of the Italian territory, she ceased to be a republic, and despite the desperate efforts of her best citizens she became an empire. The larger the territory, the greater are the inequalities between the inhabitants, and the greater the danger of despotism. To our eyes kingdoms like those of Dahomey, of Ashantee, or of Uganda, may not appear very large, but to negroes, whose minds are unable to grasp anything very complex, they seem immense. In fact, some savage rulers believe themselves to be real gods,—believe without a shadow of doubt that their ancestor created heaven and earth; they are persuaded that the limits of the habitable world are not far beyond the boundaries of their petty dominions. We are expressly told by travellers that their subjects hold them in greater reverence than divinities. The innumerable varieties of governments are perplexing to ethnologists, who find often the most heterogeneous forms side by side, and see intelligent and courageous nations submit to a tyranny which would often appear intolerable to their neighbors. Forces are constantly in operation, of which some tend to increase the liberty of the citizen, and some to increase the authority of government. If we are believers in the general principle that self-government is the best, then we shall be astonished to find how often it has been obtained by nations which we deem much inferior to ourselves. So-called savages possess a degree of freedom and enjoy an absence of restraint which well may kindle the enthusiasm of the youthful readers of Fenimore Cooper, and provoke melancholy reflections in many people who feel over-governed and ruled down, who complain that the price which we pay for the blessings of civilization is too high.

For the men who exercise power it is dangerous not to have an eye open, if not to the general benefit, at least to the interest of some powerful class. This fact is often disregarded; historians easily overlook the circumstance that a ruler, however violent, rash, and headstrong, is in most cases but the tool, conscious or unconscious, of a party. Because orders are given in his name alone, it is not remembered that in reality he acts not in his personal capacity, but as the general manager of a joint-stock company with numerous shareholders. If we revert to the historic origin of authority, it is highly probable that the gens, to which is attributed the interior organization of the tribe, has been also the most efficacious constituent of political power. The most powerful gens taking the lead of the other gentes, the head of that gens became easily the regular chief of the tribe. Such a government might as easily become republican as monarchical or oligarchic. To the Commoners of the English Parliament corresponds the assembly of the people,—that is, of all the gentiles; to the senate, or Lords, corresponds the council of the elders and chiefs of gentes. Either the council, or the assembly, or both together, entrusted the executive power to one pre-eminent official, who may have exercised at once the functions of priest, general, and chief justice,—for in early times the cumulation of offices was the rule, and the division of labor was the exception. In his interesting book, *La Cité Antique*, which depicts society under the posterior gentile organization, M. Fustel de Coulanges represents the *paterfamilias* as being at once a tiller of the soil, a warrior, a judge in his own household—invested with the power of life and death over his wife, his children, and his slaves,—a priest and an offerer of sacrifice when officiating before his sacred hearth. The *rex* or *basileus*, acting on behalf of the whole city, was the representative paterfamilias, acting in the name and on behalf of all his brethren.

Property is an institution which stands second in importance to none. Property went on increasing in amount from the hunting and fishing period to the pastoral, and from the pastoral to the agricultural—not to stop there. Riches increased in proportion to the intelligence and to the amount of work done. As riches accumulated, so increased not only the greed but, what is an apparent contradiction, the need for them. The men in authority, the strong, took more than their share, the weak growing constantly weaker, the poorer becoming either paupers or slaves. When riches were made fairly abundant by agriculture, the pristine gens with maternal kinship had to give way to the gens with paternal kinship; for it was contrary to logic that the privileges of riches and power should be still bestowed by enslaved women when the circumstances of family life established a sufficient certitude of paternity. Thus internal revolutions modified totally the character of the gens in the course of time. It had begun by being feminine in character, it ended in being exclusively masculine. Originally property was held in common by all gentiles; by degrees its ownership became restricted to constantly diminishing circles of relations, and finally an end was made of collective property; the principle of private ownership obtained the victory, and reigned supreme as it does now.

And when, in the leading states, the principle of collective property which underlay the gens had lost its vital force, the gens fell or was overthrown and crumbled to dust. This mighty fabric, the most considerable perhaps of all human institutions, has broken down everywhere, but it has not been totally destroyed. Its *débris* lie broadcast over the earth, from Rajputana to Scotland and Ireland, and thence to America. In the still existing *House or Village Communities in the East and West*, as described by Sir Henry Maine, we see living remnants of that institution in which formerly all ideas of peace, industry, justice, and progress had centred. Once the gens was all, and it was believed that it would remain all to all time. At that period, the gens was a political and a religious no less than a family institution; each gens was a complete state in itself. Where the gentes absorbed all the members of the tribe, leaving nobody out of its pale, and giving a fair share to all, the institution was perfectly compatible with progress, at least for a long time. But it happened otherwise in many instances, and especially among the gentes which are the best known to us, those of Greece and Rome. There the gentes took advantage of the fact that they were the first organized body to arrogate all power, and most obstinately they kept it, making themselves a privileged class, ruling a mob of paupers, exiles, fugitives, runaway slaves, and their progeny the *proletariate*. Theoretically the gens might have endured for ever, if it had consented to take up outsiders. But collective bodies lack generosity, especially when they are powerful. The gentiles went on increasing the number of non-gentiles by their raids and wars, conquering and enslaving other free men, until the privileged ones were outnumbered, outwitted, and finally ousted from power by the multitude of the non-possessors. And thus sovereignty, which for long ages rested upon the family system, rests now upon the territorial system.

VII. *Intellectual Development, Language, Literature, and Arts.*—To no other auxiliary science is ethnology so much indebted as to philology. Not long ago the two sciences were confounded with each other, and purely linguistic disquisitions went under the name of "ethnographic researches," as in the *Atlas* of Balbi, where the word "ethnography" occurs perhaps for the first time (in 1826).

Formerly the words "nations" and "languages" were synonymous. In Genesis the confusion of the tongues is said to have caused the separation of mankind into nations. A language is to be considered as the collective brain of a nation; the vocabulary shows the richness of its ideas, the syntax how it works them. While our lexicographers count their words by the ten thousands, we are assured that the savage is scarcely able to use more than twelve hundred words, and that many English rustics have not more than four or five hundred words at their disposal. A nation's language is the sum of its developed intellect, the record of its previous intellectual efforts. From that store of accumulated ideas and feelings our children draw the best part of their information, the most of their morals. Our mother tongue is our intellectual motherland.

For a long time, the element of race had been considered to be the greatest of all ethnological factors. Some even drew between Aryans and non-Aryans a line which would have been scarcely sharper if it had been between men and brutes. But after all, affinity of blood seems to have much less influence on men than the affinity of religions, and the affinity of religions less than the affinity of languages, at least in modern times,—for this reason, that language is the sum, and religion a part only of our thoughts. A curious example of the power of language is observed in Roumania. Its inhabitants claim descent from Italian colonists, an obscure and certainly very mixed stock. For a time they were thought to have disappeared among the Slavs, whose Greek religion had already conquered them, and already acted powerfully on their language. But the language which had been brought to the plains of Moldo-Wallachia by poor soldiers and ignorant peasants stubbornly resisted extinction, and at last obtained the advantage over its invader, because as a vehicle of thought it brought with it the ideas and memories which are preserved in the pages of Virgil and Cicero, and finally the Roumanians elected to enter into the fellowship of Latin nations. It is the English language which in the United States has welded into one nation the motley crowd of immigrants landing from so many countries and professing so many religions.

Ethnologists, as such, are not concerned to inquire into the difficult problem of the origin of languages, which is to be worked out by the professed philologists. The solutions, however, which seem self-evident to linguists on mere philologic grounds, if they do not tally with ethnological experience, will have their acceptance postponed by ethnologists until further examination. For example, some authors will have it that nations must be considered as belonging to different races, and descended from ancestors of totally inconsonant minds, if one uses as a prefix what another would use as a suffix, or if one puts the attribute after the substantive when another puts it before. Between the *isolating*, the *agglutinative*, and the *inflexional* languages they have drawn the same distinctions as those established by the botanists between acotyledonous, monocotyledonous, and dicotyledonous plants; and they want the ethnologists to classify nations accordingly,—the last of the three, *i.e.*, the inflexional, being supposed to have a preponderance as great as that of the vertebrates over the invertebrates. And, furthermore, considering that the inflexional languages are less sonorous and abundant in forms than they were in their earlier stages, philologists took much to heart what they regarded as a linguistic deterioration. From that degeneration theory there is an easy transition to the belief that language is a divine revelation, or at least a sudden and spontaneous birth in the soul of every race (Renan). This theory, which presupposes the plurality of races, may be very acceptable to philologists, but is one with which most ethnologists do not agree. Where philologists see a difference in nature, ethnologists see rather a difference in degree; they object that "it must not be by any means supposed that complexity in language implies excellence or even completeness."

What mere philologists call debasement, philologists who are also philosophers call improvement. Mere artists or calligraphers may deplore the deterioration of hieroglyphics with elaborate drawings into a cursive, demotic writing, which has led to the adoption of our unpicturesque alphabets. "The phonic alteration," says an able linguist, Mr. Michel Bréal, "helped the emancipation of thought; it furthered the first steps of man in the path of abstract thought; it gave to the human mind the same assistance as algebra gives to the mathematician, when it substituted signs more abstract still." Mr. Sweet (*Language and Thought*), considering it an amelioration that English has cast off "an effete inflexional system," does not lament that "English is to be compared in part with agglutinating in part with isolating languages, such as Chinese."

These reservations are made not because ethnologists think little of philology applied to ethnologic research, but rather because they know that alliance to be a vital necessity, and hope by concerted action to increase its usefulness. Philology, like history, was long limited to a study of the Greek and Latin languages, until it was made a totally new science by the discovery of Sanskrit, and by the vocabularies which travellers collected from all parts of the globe. In the hand of modern observers, such as Bopp, Schleicher, Fick, Max Müller, Friedrich Müller, Curtius, Pictet, philology has become a sort of telescope by which human sight penetrates the night of centuries long past. "By marvellous efforts of sagacity it has reconstituted the social state, the uses, the ideas, the beliefs of the ancient Aryas, whose moral history is now better known to us than some periods of Roman history. It has discovered bonds of parentage between nations which, as the Greeks and Persians did, reproached each other with being barbarians, and it has descried a diversity of origin between nations which, as the Greeks and Egyptians, thought themselves to be closely allied" (Bréal). How the sagacity of the philologists adds to the achievements of ethnology is shown by Peschel, who thus sums up the results of their labors for finding out where was the cradle of our Indo-European ancestors:—

> "When the ancient vocabulary of the primordial Aryan age is restored by collecting the roots common to all the members, we at the same time obtain an outline of the social condition of these nations in the most ancient period. We thus learn that they already tilled the ground, ploughed it with oxen, used carriages with wheels, kept cattle for the production of milk, and ventured on a neighboring sea in rowing boats, but did not use sails. It is more than doubtful whether they smelted metals, especially as the name for bellows is not derived from the primordial place of abode. As they were not acquainted there with the ass and the cat, both ancient domestic animals in Africa, they had not as yet interchanged any of the treasures of civilization with the Egyptians. As they had the same terms for snow and winter, and the other seasons afterwards received different names, we may be certain that in ancient Arya there was an alternation of hot and cold months. In these primitive abodes dwelt bears, wolves, and otters, but there were neither lions nor tigers. It lay eastward of Nestus in Macedonia, which in the time of Xerxes was the limit of the European lion. It was also further north than Chuzistan, Irak-Arabi, and even than Assyria, where lions are still to be met with. It cannot have included the high lands of west Iran and the southern shores of the Caspian Sea, for tigers still wander in search of prey as far as those districts. Hence every geographer will probably agree that the Indo-Europeans occupied both slopes of the Caucasus, as well as the remarkable gorge of Dariel, and were in the habit of visiting either the Euxine or the Caspian Sea, perhaps both."

Mr. Hyde Clarke shows that the original names of some African weapons are still names of stones,—an interesting circumstance, as the belief gains ground in some quarters that the despised Negro invented the smelting and the working of iron, a discovery which ranks second to none, and to which are mainly due the wonders of our modern civilization in this, the true Iron Age. Geiger claims to have proved that, as recently as the Homeric period, men had a very imperfect and even deficient perception of colors. Bolder still is Herr Fick, who has construed some hundreds of proper names by which the "Proethnians," supposed ancestors of the Celts, Germans, and Zends, may have been called before Sanskrit was yet born. Many other proofs might be given that philologists, who quite recently dared not, as it were, lose sight of the Mediterranean coasts, now navigate the most distant seas, far beyond the Ultima Thule of yore.

Language is the highest work of a nation, a work of art, and often a nation's only one. The study of languages leads to the study of popular poetry, of songs, of dances, and of music, all subjects upon which we possess a mass of information, but little knowledge. The details are ready, collected from all parts of the world, but the synthesis has not yet been made.

It is a curious fact that very accurate and even artistic etchings made on bone or horn, with the point of a flint, are found in the remains of the early stone age, but are wanting not only in the later part of the stone age, but also throughout the so-called bronze period. The ornamentation of pottery was very rude and scanty, progressing very slowly, but in the age following it seems to have taken a start—imitations of plants and animals being assayed. The Eskimo are fair draughtsmen. The Indians draw like children. Polynesians do not draw, but carve and paint. The Bushmen and Kaffirs have no idea of perspective, the Chinese very little. Drawing on a flat surface requires a certain degree of thought, and encountered probably much prejudice, because it was supposed to catch the shadow, or the soul of the objects. Carvings and mouldings in clay were easier, not to execute, but to attempt. It is beyond question that personal ornament was the beginning of art. Savages are passionately fond of adorning their persons with painting (probably the hunters of Cro-Magnon, Schussenried, and Thayingen bedaubed themselves with the ochre found near their bones), with tattooing, with all sorts of necklaces, bracelets, necklets, armlets, leggings, breast-plates, and stomachers, with fantastic head-gear, and quills, pearls, shells, and rings through the nose, ears, and lips. Even the front teeth have been inlaid with shining knobs, as among the Dyaks. We are, in this department, encumbered by a mass of details, which require to be systematically arranged, examined, and compared, in order that they may become part of a science, or even a science by itself.

VIII. *Religious Development, Myths and Legends, Magic and Superstition.*—Controversies have been waged upon this question—"Do any tribes exist which have no kind of religion?" What made the dispute interminable, and of little profit, is the fact that the disputants attached different meanings to the same word. Reports of missionaries were quoted, some affirming, some denying. Thus facts have been brought forward to prove either that the Russian peasants are very religious or very irreligious. The truth is that the religion of these simple-minded people is so mixed up with superstition that rigorous critics who maintain that superstition is the reverse of religion, as much as of morals, have no difficulty in proving that many of these country folks practise real Shamanism under the cloak of Greek Christianity. But ethnologists are not expected to be either severe or indulgent; they have to give a definition covering the ground occupied by all religions, be they true or false. Their definition of the word, although a philosophic one, falls in with that which many theologians have formulated. "Religion is the feeling which falls upon man in the presence of the unknown." Man fears and must fear the unknown, because the unknown may be dangerous and terrible, because the infinite is hidden in the unknown. Man personifies the Unknown; when his mind is strongly excited, he cannot do otherwise. And that personification he seeks to propitiate.

As regards superstitions, while moralists and social reformers consider them to be baneful weeds which it is their duty to dig out and destroy, ethnologists consider them as wrecks of former beliefs, over which the waves of many centuries have washed. The symbol has remained, but its significance is gone; the comprehension, never more than superficial, became lost, but the reverence was great, and survived. Thus, paganism underlies Christianity still, especially among ignorant rustics, a fact which the word pagan itself illustrates (*pagani*, country folk).

Classic paganism, the product of a late idealism, was in its theory too philosophic to be understood except by the few; it propounded the worship of the sun and æther as male principles and sources of light, heat, and life. It had succeeded to the so-called chthonic religions, of which Professor Bachofen (*Mutterrecht*) and M. Jules Baissac (*Les Origines de la Religion*) have been the exponents. The Earth Mother was then the centre of stellar, solar, and lunar deities, lunar deities especially, the moon being often considered as of the male sex. From internal evidence, it may be supposed that these religions were devised under the influence of agricultural practices, when the idea of paternal filiation began to be slowly evolved from the maternal. And the chthonic religions were themselves in their origin an innovation upon animal worship, which corresponded to the rise of Totemism (M'Lennan, Spencer) upon Shamanism, and the still ruder Fetichism. The lowest religions are characterized by their containing the greatest proportion of magic and the least of science and morality. In that stage, the invisible powers of witchcraft and sorcery are made to explain whatever is not understood,—even the fact of natural death, the explanation of which one would have thought to be the first to loom on these dark intelligences. But seeing around them so many violent deaths, among men as well as among brutes, they believed that all deaths, and even all diseases, were owing to magic.

Magic has been analyzed. Its essence is the belief in the action of spirits or souls of dead men. That belief is called ANIMISM (*q.v.*) by Tylor, whose researches on the subject constitute one of the most important results of English ethnology. He says—

> "Animism characterizes tribes very low in the scale of humanity, and thence ascends, deeply modified in its transmission, but from first to last preserving an unbroken continuity, into the midst of high culture. Animism is the groundwork of the philosophy of religion, from that of the savages up to that of civilized men; but although it may at first seem to afford but a meagre and bare definition of a minimum of religion, it will be found practically sufficient; for where the roots are, the branches will generally be produced. The theory of animism divides into two great dogmas, forming parts of one consistent doctrine; first, concerning souls of individual creatures, capable of continued existence after death: second, concerning other spirits, upward to the rank of powerful deities. Spiritual beings are held to affect or control the events of the material world, and man's life here and hereafter; and it being considered that they hold intercourse with men and receive pleasure or displeasure from human actions, the belief in their existence leads naturally, sooner or later, to active reverence and propitiation."

Indications are not wanting that prehistoric men were addicted to magic. In the Swiss lake-dwellings, crescent-shaped implements in baked earth have been found, which are supposed by some to be amulets, and related to moon worship; and the absence of all bones of hares in the kitchen middens is generally explained by a superstitious avoidance of that animal's flesh.

Superstition or prehistoric religion still survives even in the heart of civilized Europe, where many of its bizarre and grotesque practices are to be found similar to those prevailing in China, and in the dark corners of Africa and Australia. How is this universal prevalence to be explained? Does it prove that the communications between distant members of the human family were more active than it is commonly supposed that they were? Does it prove that we did all come from the same stock? Or is the true explanation this, that the similarity of effects results from the similarity of causes, and that men evolved analogous beliefs because they have analogous minds? Mr. Herbert Spencer (*Animal Worship*) is of opinion that, considering the sum of knowledge which primitive men possessed, and the imperfection of their signs of language and thought, the conclusions which they arrived at were after all the most reasonable. Till recently sensible men did but shrug their shoulders when they heard of superstitions. They had little thought of collecting them with care, and still less of studying them in earnest as subjects of scientific inquiry, and precious as embodying the oldest accessible thoughts of mankind. Some beginning has been made. Brandes, Henderson, and Wright in England, Wuttke in Germany, Kreutzwald in Esthonia, Grohmann in Bohemia, Dennys and Doolittle in China, and many others have collected precious documents. A mass of material lies scattered about, especially in books of travels. Explorers in this field of inquiry ought not to be repelled by the amount of nonsense they encounter; the more absurd the text, the more ancient and genuine it probably is. Most things would be inexplicable if they stood alone, but one explains another. Here, as in natural history, the value and signification of the individual object is best perceived when it is examined in the series to which it belongs.

Fairy tales and popular legends find little favor with many enlightened people. Of course if these tales were to be taken literally, they would be pronounced pure nonsense, but their meaning, like that of poetry, is an ideal one; they are intended to please and invigorate the imagination of children. In ancient times, when their primitive form and meaning were less altered, they had a higher purpose. Those mixed up with animal stories of a certain character appear to have been Buddhist parables intended to teach fairness and goodness towards "the weaker brethren." But although twenty centuries old and more, they belong to the later creations in the development of human thought. The oldest stories are scraps of prehistoric myths, cosmologies, and epics. Although they have been patched up a thousand times, they have still kept enough of their original traits to be still recognizable.

And it is not only popular tales and proverbs which are to be regarded as records of ancient lore, but also children's plays, nursery rhymes, and infantine dances, as has been pointed out by Tylor and by Rochholz (*Kinderlied und Kinderspiel*). Among Kirghiz, Chinese, Redskins, and Bantu negroes, counterparts have been found to the *Iliad* and the *Odyssey*, to the grand myths of Hercules and Prometheus, to the traditions of the Argonauts, of Danae, Andromede, Proserpine, not to forget the most charming romance of Psyche. During the Middle Ages many of those tales were bedaubed with theological additions, and transformed into hagiologies and "Golden Legends." As such they had a separate existence, but fortunately they did not obliterate the recollection of the originals from which they sprang. Struck with a happy idea, and wishing to prove that the moderns were as good as the ancients, Charles Perrault put his *Contes* into writing, which he little suspected to be as old, and even of the same covey as those of the Greeks. His narrations were gems of elegant simplicity, and their success caused them to be followed by many similar productions, which were enjoyed as light literature, their scientific import being little suspected, until the brothers Grimm collected the *Deutsche Hausmärchen*, one of the most popular books published in this century. These savants opened a most fertile field of investigation by their discovery that many German popular tales had for their substratum German mythology. Adalbert Kühne's *Herabkunft des Feuers* marked a new step. He showed most clearly that our tales have the same relation with the old Vedan mythology as our languages with the Sanskrit. Benfey proved by other considerations the same thesis. Following them, M. Bréal gave in his *Mythe de Cacus* a model of science made clear and pleasant. A host of diligent searchers, mostly Germans, for the Germans have taken the lead in this department, devoted themselves to collecting, translating, commenting upon popular tales, songs, and mythology. Folk-lore now constitutes quite a special literature. We have already legends from all five parts of the world, legends from nearly every important country, and in some countries from almost every province. The immense task of sifting and reconstructing prehistoric mythology has next to be commenced.

IX. *Justice and Morals.*—Law is anterior to justice. The lower races, says Lubbock, are deficient in any idea of right, though quite familiar with that of law. In fact, civil law, in its origin, is a custom and nothing else,—a custom meeting some particular want. Therefore laws will not last if they be arbitrary, if they be founded on the caprice of a legislator, and do not subserve the interests of the majority. True laws are the expression of the people's will; legislature and magistracy are delegations of the people's authority. In primitive communities such delegation is often uncalled for; the community acts directly as judge and law-giver, its resolutions being guided not by abstract principles of justice, but by self-interest and a desire for self-preservation,—seldom, if ever, by unselfish considerations. "*Salus populi suprema lex.*" As the community enlarges this feeling widens and becomes generalized; by degrees the idea of justice is evolved out of common convenience. Absorbed by their petty local interests, early tribes could scarcely realize the idea of absolute justice, which is inseparable from the idea of mankind at large. Both ideas are of a recent origin; they seem contemporaneous with the rise of the Roman empire, when it strove to take possession of the whole world, and when the positive principles of jurisprudence were set forth with a logic, a vigor, and a lucidity not surpassed, not even equalled since. Our civilized countries have enriched themselves with a ponderous apparatus of written laws, which are, or are affirmed to be, the outgrowth of customary laws, and an accepted fiction sets forth that every citizen knows and understands perfectly that immense miscellany of rules and statutes.

Criminal law has a similar origin; it is the part of justice evolved out of vengeance, which, from being with some animals and the lowest tribes a boundless passion, was by degrees restrained, acquired a definite form, and became the law of *retaliation*,—"an eye for an eye and a tooth for a tooth." From that principle men were sure to infer, "Do not to others what thou wouldst not like to be done to thyself,"—the negative side of a principle which was far sooner understood than its positive side, "Do unto others as ye would that men should do unto you." The abandonment of *vendetta* is one of the steps which lead from semi-civilization towards civilization. But its adoption by primitive communities had in its time heralded an improved state of things. Its principle is that all the members of a gens are bound to avenge the death or the hurt of any individual member. Thereby the gentiles were involved in continual troubles. By degrees they came to find out that the surest way to minimize the troubles arising out of vendetta was to avoid its causes. This led to the softening of manners. The next step was for the gens to impose upon its affiliates the obligation to resort directly to its tribunal in case of offences. Thus by degrees redress came to be substituted for revenge, and justice taken at one's own hand to be regarded as fit only for barbarians.

Like the tribe, the gens was for its members an enlarged self, and its motto was—One for all, all for one,—an ideal motto among brothers in a brotherhood, but one fit also to promote strifes of brotherhood against brotherhood. Friendship, honesty, justice, and even self-sacrifice within the circle of kinship; cunning, violence, murder, ruthless brutality outside. The gentile stood by the gentile for weal or woe, for wrong or right. Men's minds and hearts are now so far enlarged that they can embrace the idea of a whole country, their own. But have we gone really much further?

X. *Progress.*—Ethnology, in its actual state, centres upon the theory of progress. It has not only to prove the existence of progress, it has to demonstrate how it operates, and to measure the amount of its work in the different periods. Progress, put in question in all the branches of human development, is nowhere more fiercely discussed than in its relation to justice and morals. This is the most important, the most interesting, and also the most perplexing theme. It is the easiest to discourse upon, as there are no external standards by which to measure internal phenomena, no fixed canon by which to compute the ever-shifting correlations between the two great principles of social order and individual liberty—custom and progress, which, far from working harmoniously together, clash so often one against the other. This question is not merely a theoretical one; it has very practical bearings, now that our civilization is about to take possession of all the world,—now that representatives of our culture invade in so many places the soil occupied by less advanced communities. Before the last remainders of ancient ages be destroyed, it is certainly worth while to pause and to consider, Are we right in doing away with them, and will the world at large be a gainer by it? The United States, the colonial administrations, are constantly called on to deal with native reserves, native wars, and, alas! with native extermination. We cannot forget that the landing of Columbus at Guanahani cost the lives of many millions of American and African aborigines, and that the last Tasmanian, the last Guancho, the last Beothus, have been "improved" off the face of earth. We can hardly regard with unmixed feelings the prospect that the whole of the African continent will soon be open to "European enterprise."

We will give an epitome of the debates which are carried on, striking off many arguments for the sake of brevity. It will be but fair to give the first word to a friend of the attacked and (must we say?) the doomed races.

> Mr. Wallace, after having given a charming picture of some Malay communities which he had visited, tells us: . . . "Each man scrupulously respects the rights of his fellow, and any infraction of these rights rarely or never takes place. In such community all are nearly equal. There are none of these wide distinctions of education and ignorance, wealth and poverty, master and servant, which, while they increase wealth, produce also conflicting interests; there is not that severe competition and struggle for existence or for wealth which the population of civilized countries inevitably creates. . . . It is very remarkable that among people in a very low stage of civilization we find some approach to a perfect social state. It is not too much to say that the most of our populations have not at all advanced

beyond the savage code of morals, and have in many cases sunk below it."

Such pictures as that drawn by Mr. Wallace are not unfrequent, and we might have transcribed many pleasant descriptions of the peace, concord, and fraternity reigning among the Todas, Aleutians, and some other primitive communities.

Now comes the indictment by Lubbock, Tylor, and others. It is a heavy one.

> "The Veddahs of Ceylon are of opinion that it signifies little whether they do right or wrong" (Davies). "To Australians the words good and bad had reference to taste or bodily comfort, and did not convey any idea of right or wrong. . . . The whole tendency of their system is to give everything to the strong, to the prejudice of the young, and more particularly to the detriment of women" (Lang). . . . "To believe," says Sir George Grey, "that man in a savage state is endowed with freedom, either of thought or action, is erroneous in the highest degree. . . . Offences, in Fijian estimation, are light or grave according to the rank of the offender. . . . In Tahiti the missionaries considered that no less than two-thirds of the children were murdered by their parents." . . . "Conscience does not exist in Eastern Africa. Repentance expresses regret for missed opportunities of mortal crime. Robbery constitutes an honorable man. Murder—the more atrocious the midnight crime the better—makes the hero" (Burton).
>
> And is civilization anything else? reply the others. Is it not the same struggle for existence, but here on a gigantic scale? Is not our incessant battle for life little short of wholesale murder? Is it not accompanied with the same envy, with the same remorseless hatred, but under a thicker veil of perfidy and hypocrisy? The Anthropological Society in London was told by the late Winwood Reade that among the savages of Africa he had not seen anything as bad as the pauperism, as the mass of misery and degradation, to be found in our large cities. The Anthropological Society of Paris was told by Mr. Coudereau that in our modern Europe the moral and intellectual development of the multitude is not superior to that of the Dahomians. It was said by Mr. Lavrof: "Between our peasants and the primitive savages there is little difference. The religions and the most advanced philosophies, which hold so large a place in the history of mankind, have never been taken up in reality except by a minority numerically insignificant. Were they profitless to the majority? No, they enriched it with new amulets, new magical signs, new forms of divination. And when practical results of science, such as the electric telegraph, enter into common use, their real signification is as little understood by our country folks as it would be by the Marquesas Islanders."

Although there may have been some exaggeration in the expression, the facts which have been alleged on both sides are true; none are to be explained or trifled away.

Thus it is evident that among civilized men all is not satisfactory, while among uncivilized all is not unsatisfactory. We are led to infer that civilization amplifies and intensifies its elements. We had already occasion to note that among ourselves the extremes are wider apart than among the barbarians. We can say that we are at once materially much better and much worse off, and morally much better and much worse, than savages. And as to man himself it can be said that of all ferocious brutes he is the most cruel, and of all gentle animals the most affectionate.

Can material progress be disputed? An increased production of food has enabled greater numbers of men to live; their daily ration of eatables and drinkables has been increased; the quality of their vestments has been improved; most people do not dwell in damp holes dug in the earth; they do not any longer roost in the branches of trees. Not to speak of other comforts, the inventions of lucifer matches and of candles have been splendid achievements in their day. That the intellectual progress has been prodigious from the time when our forefathers were unable to count their own fingers, even of one hand, as Spix and Martius tell of the Brazilian Wood Indians, to the transformation of mathematics into a powerful scientific engine, to the calculations of Newton and Laplace, to the wonders of spectral analysis, is a position nobody dares to impugn.

Material and intellectual development being satisfactorily settled, we touch upon the vexed question of moral progress. Mr. Wallace says—"While civilized communities have increased vastly beyond the savage state in intellectual achievements, we have not advanced equally in morals." It may be said with equal truth that this progress has been immense, and that it has been ridiculously small,—immense, if we consider that there is an infinite distance between nothing and something; very small indeed, if we gauge the precise amount of that something. But that actual something will appear larger if we trace it to its original state, of which we do not find the like among the present savages. Their abject condition, abject as it has been depicted, is yet vastly superior to that of the supposed primeval man. Everything tends to prove that mankind, far from being born with a vivid sense of right and wrong, as the common doctrine will have it, had to evolve a moral sense by a long process. Through ages man must have collected sensations of a peculiar sort, which at first were slightly perceptible, and which, when accumulated, became that positive perception, the most to be cared for of our inherited abilities. "The world is very young," said Mrs. Mill, "and has only just begun to cast off injustice." And we hold to be survivals of antecedent ages the instances which show among civilized and uncivilized an utter absence of morality, the lack of all fairness and generosity. But in our times these instances are exceptions. On the average, we know better than the Bechwana, who, being asked what it meant "to be good," was much puzzled, but finally answered, "To be good it is to possess a wife and cows, and to steal one neighbor's wife and cows;" or than the Pawnee, who said, "He is a good man who is a hunter sly, crafty as a fox, daring and strong as a wolf."

A last question arises—If moral progress be a positive fact, how could it be denied by intelligent observers? First, progress is far from being always evident. Its course runs not incessantly onwards in a straight line at a uniform speed; it proceeds by irregular motions and sometimes by curved, by broken, or even by spiral lines. Then we are apt to underrate a progress which has become a habit. The pleasure which an improvement gives us does not last longer than its novelty. Very soon we become used to it—and then we become conscious that some evil, which we had till then borne patiently, has grown insufferable, and must be quickly done away with. We feel to the quick injustices and iniquities which ages ago we would have submitted to without complaint,—of which we would have been participants. Till mankind reaches some goal yet unknown to us, its motto seems to be, Never to rest, never to be thankful.

Thus ethnology may be considered as the science which builds up the history of material and intellectual progress, which retraces the evolution of that attribute, precious and delicate, of which Dr. Maudsley has finely said, "Morality, the last acquired faculty of man, is the first which he is liable to lose."

XI. The *Bibliography* of ethnology may be regarded either as very extensive or unimportant, according as we include all books in which ethnological subjects are treated, or as we exclude all books which have not ethnology for their primary object. Although possessed of immense territories in copartnership with the sister sciences, ethnology holds but a limited province of its own. This remark disposes of the largest mass of ethnographical bibliography, in a work which contains bibliographies of other sciences.

Works which take up the new science as a whole, and bring its various problems together, cannot as yet be very numerous, especially if the demarcation between ethnology and anthropology is maintained. In the preceding pages the titles of most current books which are acknowledged as authoritative have been mentioned, and for brevity's sake will not be repeated. One of the most important publications, the object of which is to set the science on a solid foundation, is in progress. The *Descriptive Sociology* commenced in 1867 by Mr. Herbert Spencer, devised, classified, and arranged by him, is compiled and abstracted by Messrs. James Collier, Richard Scheppig, and David Duncan. "The digests of materials, thus brought together, will supply the student of social science with data, standing towards his conclusions in a relation like that of which accounts of the structures and functions of different types of animals stand to the conclusion of the biologist. Until there had been such systematic descriptions of different kinds of organisms as made it possible to compare the connections and forms and actions and modes of origin of their parts, the science of life could make no progress; and in like manner, before there can be reached in sociology generalizations worthy to be called scientific, there must be definite accounts of the institutions and activities of societies, of various types and in various stages of evolution, so arranged as to furnish the means of ascertaining what social phenomena are habitually associated."

In the three volumes of Adolf Bastian, *Der Mensch in der*

Geschichte, we have already a kind of ethnological encyclopædia, a mine of interesting facts, collected from the most various sources. The author is a man of great reading, and has himself travelled over the known world. But in 1860, when the book was written, ethnology had not come of age, and instead of allowing the facts to speak for themselves, he marshalled them in ungainly array to make them support metaphysical theses.

Amongst other important books relating to general ethnology are to be named—Klemn's *Allgemeine Culturgeschichte der Menschheit;* Caspari's *Urgeschichte der Menschheit;* Fr. von Hellwald's *Culturgeschichte;* Waitz's *Anthropologie der Naturvölker;* Fr. Müller's *Allgemeine Ethnographie;* Gerland's *Anthropologische Beiträge;* Baer und Schaafhausen, *Der vorgeschichtliche Mensch;* Huxley's *Methods and Results of Ethnology;* Brace's *Manual of Ethnology;* Von Martius, *Ethnographie.* Mr. H. Bancroft's *Native Races of America* and Meinike's *Polynesia* cover only parts of our ground, but deserve exceptional record here, from the amount of information which they afford.

Ethnographical maps have been published by Berghaus, Schafarik, Fuchs, Czoernig, Waitz, and others. In Germany, Denmark, and Sweden "maps of the finds" are in progress. Dupont has given out important *Synoptic Tables.*

An ethnological feat, accomplished with the resources of a national budget, that of Austria, is the *Novara Expedition,* which continues the series of the great scientific travels, such as those of the "Beagle" and the "Astrolabe," and those accomplished by Cook, Forster, and Bougainville. The relations given by travellers of what they have seen in foreign parts compose an immense collection, which ethnographers have now to classify, and to sift carefully in order to extract from it all that is useful. Modern descriptions have their peculiar merits, but the value of earlier writers increases in proportion as civilization, which is gradually imported everywhere, destroys the old order of things, and gives a uniform tinge to the intellects and the institutions of all races. Narrations of the mediæval travellers, such as Marco Polo and Ibn Batutah, were never found so interesting as they are now. We peruse again the stories of the *Conquistadores*, the barbarous heroes of modern culture, and those of their twin brothers, the *Conquerors of Faith,* the missionaries of the third Christian period, Franciscans, Dominicans, Jesuits, whose work among the Indians of North and South America, among the races of Africa, the Chinese, and the Japanese, is related in the celebrated collection of the *Lettres Édifiantes.* Acosta, Lafitau, Charlevoix, Duhalde, Dobrizhoffer, have given to the world much information, as have also the modern missionaries, chiefly Protestants, among whom we may cite Williams, Ellis, Isenberg, Krapf, Moffat, Callaway, Casalis, Huc, Eitel, Metz, and, above all, Livingstone.

Although ethnology be a new science, it must not be considered as a new invention. Thirty years ago not a few books were written in France and Germany, which, expounding the "philosophy of history" then in vogue, would now-a-days have expounded the "progress of culture." The most antiquated, inspired by the schools of Hegel and Schelling, contain less of history than of so-called philosophy; the best, inspired rather by Herder and Vico, contain more of facts than of metaphysics. Some of their authors were already ethnologists without knowing it,—among them, Buckle, whose *Civilization in England* may be considered as one of the works which open the new period of history, as modified by ethnology.

The bibliography of a science giving its history in a condensed form, it must be said that the corner-stones of any ethnographer's library are the works of the great historians Herodotus and Tacitus, and that the first expounder of the modern principles of ethnology is the poet Lucretius.

In contrast with the paucity of the publications which profess to give the synthesis of ethnology, one may notice the superabundance of books, memoirs, essays, and lesser works which discuss all kinds of ethnologic matters and points of detail. Ethnology being in great favor with the public, there appear in reviews and magazines, and even in the weekly and daily press, articles which an ethnographer should diligently collect. A list of these various publications appears every year in the Brunswick *Archiv für Anthropologie.* It is not, and could not be, complete, but, such as it is, it meets most wants.

The learned societies scattered throughout the civilized world act in scientific matters as the lakes and reservoirs of the high lands do in the hydrographic system; they collect and purify the waters of torrents and rivulets, they regulate their outlet. In all European capitals, and in some other cities, as Washington, Toronto, Rio Janeiro, Calcutta, Yeddo, Tiflis, Melbourne, Cairo, savants and scientists meet in Academies, and, in the *Transactions* of their diverse sections ethnology comes in for a part of their attention. Societies of anthropology and ethnology have constituted themselves as separate bodies in London, Paris, Rome, Florence, Madrid, Vienna, Berlin, Dantzig, Leipsic, Dresden, Munich, and Stuttgart.

From their influence and the date of their foundation, the societies of London and Paris are to be ranked first. To the impulse given by the Société Anthropologique are often ascribed the great strides recently made by anthropology. This association was founded by men who mostly went to work with a precision which originated in the methods of anatomy, physiology, archæology, palæontology, and philology, the lights from which they projected simultaneously on their favorite science. The vastness of Great Britain's colonial empire, the diversity of its climes, races, and creeds, the magnitude of England's commercial navy, which has become the general carrier of the world, the facility with which Englishmen emigrate or travel abroad, have given to ethnographic matters in this country an interest and an importance which they have not elsewhere. Hence the directness and the variety of the communications which are transmitted to the Anthropological Institute in London. The character of the two societies reflects itself in their publications; the *Revue d'Anthropologie,* as edited by Dr. Paul Broca, has a preference for biology, and the *Journal of the Institute,* as edited by Mr. John Evans and Major-General Lane Fox—the best authorities on flints and on primitive weapons and implements—has a marked preference for archæology and the domestic arts. In almost every considerable town of Germany there is some society affiliated to the large Deutsche Gesellschaft für Anthropologie, Ethnologie, und Urgeschichte, which numbers about 2000 members, and issues the *Archiv für Anthropologie* already named, edited by Dr. Virchow, Eck, Lindenschmidt, with many collaborateurs, mostly physicians and naturalists.

Another publication, more ethnological in character, is the *Zeitschrift für Ethnologie,* edited by the great traveller and most learned man, Adolf Bastian. In the Scandinavian countries, and in Hungary, patriotism fosters the prehistoric studies by the hope of throwing some light on the misty figures of gigantic ancestors. Since the discovery of the lake-dwellings, by which a sudden interest was awakened in archæological pursuits, ethnology has been a favorite study in Switzerland. Italy, which also had lake-dwellings as well as terramare, whole cities buried in the soil, etc., and which teems with precious remains of Roman, Greek, Etruscan, and Oriental origin, addicts herself with some zeal to these researches, the results being given forth especially in the *Archivio dell' Antropologia e Etnologia* and the *Paleo-etnologia Italiana.*

Not to be omitted are the *Tour du Monde,* which has been translated perhaps in every civilized language, and even into Japanese; the *Globus* of Herr Karl Andrée; the *Ausland* of Fr. von Hellwald; the *Matériaux pour servir à l'histoire primitive et naturelle de l'homme* of Cartailhac and Fontdouce. Many publications which give occasionally valuable ethnographic information, but which bestow on geography, history, and philology the largest share of their attention, must be passed over. (E. RE.)

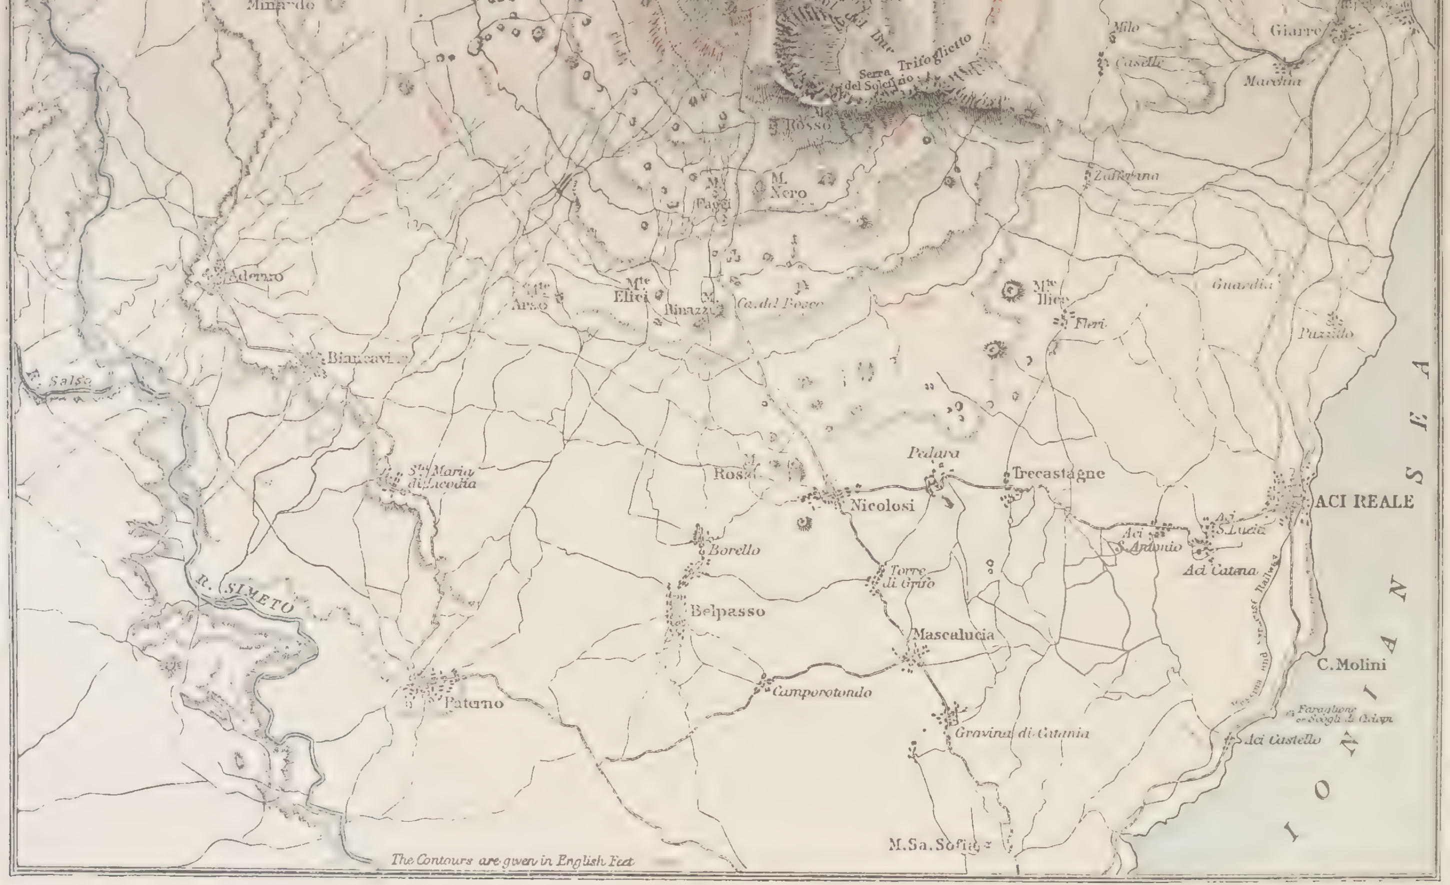
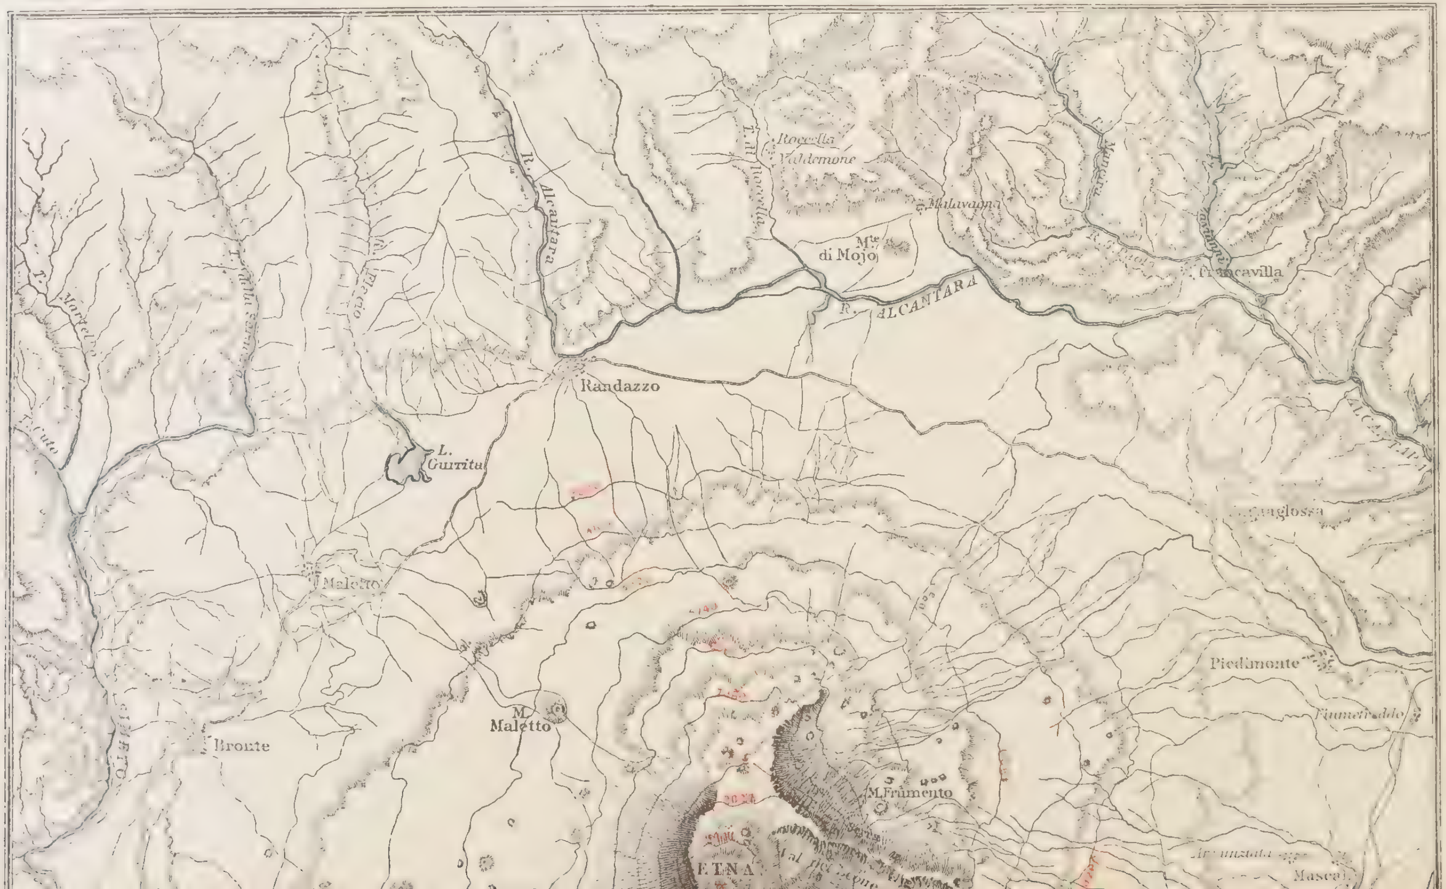
Plate VII. **ETNA.** Mount Etna, one of the most celebrated volcanoes in the world, is situated on the eastern sea-board of Sicily. Its position was first accurately determined in 1814 by Captain Smyth, who found the longitude of the highest bifid peak of the great crater to be 15° east of Greenwich, and the latitude 37° 43′ 31″ N. These results have been very generally accepted by later writers.



The Contours are given in English Feet

ETNA

Scale of 0 1 2 3 4 5 English Miles



There can be no doubt that the name of Etna—*Αἴτνα*—is derived from ἀιθω, to burn. This name was known to Hesiod. The more modern name *Mongibello*, by which the mountain is still commonly known to the Sicilians, is a combination of the Italian *monte* and the Arabic *gibel*. During the Saracenic occupation of Sicily (827–1090), Etna was called *Gibel Uttamat*, the mountain of fire; and the second portion of *Mongibello* is a relic of the Arabic name.

Historical References and Descriptions.—Etna is often alluded to by classical writers. By the poets it was feigned to be the prison of the giant Enceladus or Typhon, by others the forge of Hephæstus. The flames proceeded from the breath of Enceladus, the thunderous noises of the mountain were his groans, and when he turned upon his side, earthquakes shook the island. Pindar (522–442 B.C.), in his first Pythian Ode, for Hiero of Ætna, winner in the chariot race in 474 B.C., exclaims:—"He (Typhon) is fast bound by a pillar of the sky, even by snowy Etna, nursing the whole year's length her dazzling snow. Whereout pure springs of unapproachable fire are vomited from the inmost depth: in the day-time the lava streams pour forth a lurid rush of smoke, but in the darkness a red rolling flame sweepeth rocks with uproar to the wide deep sea." Æschylus (525–456 B.C.) speaks also of the "mighty Typhon" (*Prom. Vinctus*). Thucydides (471–402 B.C.) alludes in the last lines of his third book to three early eruptions of the mountain. Many other early writers speak of Etna, among them Theocritus, Virgil, Ovid, Livy, Seneca, Lucan, Petronius, Dion Cassius, Strabo, Diodorus Siculus, and Lucilius junior. While the poets on the one hand had invested Etna with various supernatural attributes, and had made it the prison of a chained giant, and the workshop of a swart god, Lucretius and others endeavored to show that the eruptions and other phenomena of the mountain could be explained by the ordinary operations of nature. These ideas were developed by Lucilius junior (the friend of Seneca, to whom he addressed his *Quæstiones Naturales*) in a poem consisting of 640 Latin hexameters, entitled *Etna*. Many of the myths developed by the earlier poets had their home upon the very sides of Etna:—Demeter, torch in hand, seeking Persephone; Acis and Galatea; Polyphemus and the Cyclops.

If we pass to more modern times we find mention of Etna by Dante, Petrarch, Cardinal Bembo, and other Middle Age writers. In 1541 Fazzello made an ascent of the mountain, which he briefly describes in the fourth chapter (entitled "De Ætna Monte et ejus ignibus") of his work *De Rebus Siculis*. He also gives a brief history of the mountain. In 1591 Antonio Filoteo, who was born on Etna, published a work in Venice, entitled *Ætnæ Topographia, Incendiorum Ætnæorum Historia*, in which he describes an eruption which he witnessed in 1536. He asserts that the mountain was then (as now) divided into three "regions"—the first very arid, rugged, uneven, and full of broken rocks; the second covered with forests; and the third cultivated in the ordinary manner. Of the height he says, "Ascensum triginta circiter millia passuum ad plus habet."

The great eruption of 1669 was described at length by the naturalist Borelli in the year of its occurrence. It also formed the subject of a paper in the *Philosophical Transactions;* and a brief account of it was given by the earl of Winchelsea, English ambassador at Constantinople, who was returning home by way of the Straits of Messina at the time. As the eruption of 1669 was the most considerable eruption of modern times, it attracted a good deal of attention, and was described by several eye-witnesses. A map in the *Bibliothêque Nationale* in Paris gives an imaginary view of the mountain during this eruption. It is the earliest map of the mountain which the library possesses, and is entitled "Plan du Mont Etna, communement dit Mont Gibel, en l'Isle de Scicille, et de t'jncēdie arrive par un trēblement de terre, le 8^{me} Mars dernier 1669." Further, in the sacristy of the cathedral of Catania there is a curious wall-painting, which represents broad red streams of lava descending from the Monti Rossi and overwhelming the city. Towards the middle of the next century the mountain was ascended and described by Count D'Orville (1727), by the German Riedesel in 1767, and by Sir William Hamilton, the English ambassador at Naples, in 1769. During the twenty succeeding years it was described by Borch, Swinbourne, Denon, Spallanzani, Faugas de Saint-Fond, and Houel. The last, in his *Voyage pittoresque dans les Deux Siciles*, 1782–1786, has given a capital account of the mountain, accompanied by some excellent engravings. In 1776, a clever Irishman named Patrick Brydone published two volumes of a *Tour in Sicily and Malta*, in which he describes at some length his ascent of Etna, and he further states as many facts concerning the history of the mountain as he could collect from the Canon Recupero and others. His account is more complete than any which had appeared in English up to that time, and he is frequently quoted in every account of the mountain with which we have met.

It was reserved, however, for the Abate Francesco Ferrara, professor of physical science in the university of Catania, to write the first history of Etna which has any claim to completeness. It is entitled *Descrizione dell' Etna, con la storia delle eruzioni e il catalogo dei prodotti*. The first edition appeared in 1793, and a second was struck off at Palermo in 1818. It is illustrated by a map, and by some rather rough engravings. The author was born upon the mountain, and was witness to some of its grandest phenomena. His work has evidently been to a great extent a labor of love. It is full of personal observations, while it embodies the principal results of other observers, and furnishes the foundation of all that has since been written about Etna. During 1814–16 Captain Smyth, acting under the direction of the lords of the Admiralty, made a survey of the coast of Sicily, and carefully determined the latitude and longitude of Etna; he also accurately measured the height and examined the surroundings of the mountain. His results were published in 1824, and are still often quoted as the most accurate which exist. In 1824 Dr. Giuseppe Gemellaro, who lived all his life upon Etna, and made it his constant study, published an "Historical and Topographical Map of the Eruptions of Etna from the Era of the Sicani to the year 1824." In it he shows the extent of the three regions, *Coltivata*, *Selvosa*, and *Deserta;* he lays down the places of the minor cones to the number of seventy-four; and he traces the course of the various lava streams which have flowed from them and from the great crater. About 1847 Baron Sartorius von Waltershausen commenced a minute survey, and a complete examination of the mountain, both geologically and otherwise. He was assisted by a brother professor, and by two Sicilians, and their labors resulted in the production of a fine atlas of Etna, which even in its incomplete form costs £12. Owing to the death of Von Waltershausen, the work was never quite completed, but, as it is, it supplies the most exhaustive history of any one mountain on the face of the earth. Sir Charles Lyell visited Etna three times (in 1824, 1857, 1858), and he has embodied the results of his researches in a paper communicated to the Royal Society, and in a lengthy chapter in his *Principles of Geology*. His investigations have contributed much to our knowledge of the geological characteristics of the mountain.

The most important recent contribution to our knowledge of Etna has been the fine map of the Stato Maggiore constructed by order of the Italian Government between 1864 and 1868. It embraces the whole of Sicily, and is laid down on the unusually large scale of 1 in 50,000, or 1·266 inch to the mile. The portion relating to Etna and its immediate surroundings occupies four sheets. Plate VII. is a reproduction of this map on a smaller scale. All the small roads, paths, and rivulets are introduced; the minor cones and monticules are placed in their proper positions; and the elevation of the ground is given at short intervals of space over the map. A careful examination of this map shows us that it represents the first accurate survey of the entire mountain. It shows us that distances, areas, and heights have been repeatedly misstated, the minor cones misplaced, and the trend of the coast-line misrepresented.

Height.—The height has been often determined. The earlier writers had very exaggerated notions on the subject, and a height of three and even four miles has been assigned. Brydone, Saussure, Shuckburgh, and others obtained approximations to the present height; it must be borne in mind, however, that the cone of a volcano is liable to variations in height at different periods, and a diminution of more than 300 feet has occurred during the course of a single eruption of Etna, owing to the falling of the cone of cinders into the crater. During the last sixty years, however, the height of the mountain has been practically constant. In 1815 Captain Smyth determined it to be 10,874 feet. In 1826 Sir John Herschel, who was unacquainted with Smyth's results, estimated it at 10,871½ feet. The new map of the Stato Maggiore gives 3312·61 meteres = 10,867·94 feet. The radius of vision from the summit is very variously stated. Smyth gives it as 150·7 miles, and this we are inclined to adopt as the nearest approach to the truth, because he was an accurate observer, and he made careful corrections both for error of instruments and for refraction. This radius gives an horizon 946·4 miles in circumference, and an included area of 39,900 square miles,—an area larger than that of Ireland.

Boundaries.—The road which surrounds the mountain is carried along its lower slopes, and is 87 miles in length. By reference to the map it will be seen that it passes through the towns of Paternò, Biancavilla, Adernò, Bronte, Randazzo, Linguaglossa, Giarre, and Aci Reale. By some writers it is considered to define the base of the mountain, which is hence said, most erroneously, to have a circumference of 87 miles; but the road frequently passes over high beds of lava, and it winds considerably. It is about 10 miles from the crater on the north, west, and east sides of the mountain, increasing to 16 miles at Paternò (S.W.). The elevation on the north and west flanks of the mountain is nearly 2500 feet, rising at its maximum elevation to 3852 feet, while on the south it falls to 1500 feet, and on the east to within 50 feet of the level of the sea. It is quite clear, therefore, that this road cannot be taken as the limit of the base. The natural boundaries of Etna are the rivers Alcantara and Simeto on the north, west, and south, and the sea on the east to the extent of 23 miles of coast, along which lava streams have been traced, sometimes forming headlands several hundred feet in height. The base of the mountain, as defined by these boundaries, is said to have a circumference of "at least 120 miles;" an examination of the new map, however, proves that this is overestimated. If we take the sea as the eastern boundary, the river Alcantara (immediately beyond which Monte di Mojo, the most northerly minor cone of Etna, is situated) as the northern boundary, and the river Simeto as the boundary on the east and south, we obtain an approximate circumference of 91 miles for the base of the mountain. In this estimate the small sinuosities of the rivers have been neglected, and the southern circuit has been completed by drawing a line from near Paternò to Catania, because the Simeto runs for the last few miles of its course through the plain of Catania, quite beyond the most southerly lava stream.

Area.—The area of the region inclosed by these boundaries is approximately 480 square miles. Reclus gives the area of the mountain as 1200 square kilometres = 461 square miles (*Nouvelle Geographie Universelle*, 1875).

Population.—There are 2 cities, Catania and Aci Reale, and 63 towns or villages on Mount Etna. It is far more thickly populated than any other part of Sicily or Italy; for while the population of Italy per square kilometre is 90, and of Sicily 88, that of the habitable zone of Etna is 550. No less than 300,000 persons live on the mountain. Thus, with an area rather larger than that of Bedfordshire (462 square miles), it has more than double the population; and with an area equal to about one-third that of Wiltshire, the population of the mountain is greater by nearly 50,000.

General Aspect.—The general aspect of Etna is that of a pretty regular cone with very gentle slopes covered with vegetation, except near the summit. The regularity is broken on the east side by a slightly oval valley, four or five miles in diameter, called the Val del Bue. It commences about two miles from the summit, and is bounded on three sides by nearly vertical precipices from 3000 to 4000 feet in height. The bottom of the valley is covered with lavas of various dates, and several minor craters have from time to time been upraised from it. Many eruptions have commenced in the immediate neighborhood of the Val del Bue, and Lyell believes that there once existed a crater of permanent eruption in the valley. Mount Vesuvius might be almost hidden away in the Val del Bue.

Regions.—The Val del Bue is altogether sterile, having been the frequent scene of both fire and flood, but the mountain at the same level, as its middle and lower portions, is on its other sides clothed with forests. The surface of the mountain has been divided into three zones or regions—the *Piedemontana* or *Coltivata*, the *Selvosa* or *Nemorosa*, and the *Deserta* or *Discoperta*.

The lowest of these, the *Cultivated Region*, yields in abundance all the ordinary Sicilian products. The surface soil, which consists of decomposed lavas, is extremely fertile, although of course large tracts of land are covered by recent lavas, or by those which decompose but slowly. In this region the vine flourishes, and abundance of corn, olives, pistachio nuts, mulberries, oranges, lemons, figs, and other fruit trees. The breadth of the *Coltivata* varies; it terminates at an approximate height of 2000 feet. A circle drawn with a radius of ten miles from the crater roughly defines the upward limit of this region. The elevation of points on the circumference of such a circle is 2310 feet on the north near Randazzo, 2145 feet on the south near Nicolosi, 600 feet on the east near Mascali, and 1145 feet on the west near Bronte. The breadth of the cultivated zone is about two miles on the north, east, and west, and nine or ten miles on the south, if we take for the base of the mountain the limits proposed above.

The *Woody Region* commences where the Cultivated Region ends, and it extends as a belt of varying width to an approximate height of 6300 feet. It is terminated above by a circle having a radius of about a mile and a half from the great crater. There are fourteen separate forests in this region,—some abounding with oak, beech, pine, and poplar, others with the chestnut, ilex, and cork tree. The celebrated *Castagno di Cento Cavalli*, one of the largest and oldest trees in the world, is in the forest of Carpinetto, on the east side of the mountain, five miles above Giarre. The breadth of the Regione Selvosa varies considerably: in the direction of the Val del Bue it is very narrow, while elsewhere it often has a breadth of from six to eight miles.

The Desert Region is embraced between the limit of 6300 feet and the summit. It occupies an area of about ten square miles, and consists of a dreary waste of black sand, scoriæ, ashes, and masses of ejected lava. In autumn, winter, and spring it remains permanently covered with snow, and even in the height of summer snow may be found in certain rifts near the summit.

Minor Cones.—A remarkable feature of Etna is the large number of minor cones which are scattered over its sides. They look small in comparison with the great mass of the mountain, but in reality some of them are of large dimensions. Monte Minardo, near Bronte, the largest of the minor cones, is still 750 feet in height, although its base has been raised by modern lava streams which have flowed around it. There are 80 of the more conspicuous of the minor cones, but Von Waltershausen has mapped no less than 200, within a ten-mile radius of the crater, neglecting many monticules of ashes. According to Reclus, there are 700 minor cones, while Jukes asserts that there are 600; these statements undoubtedly include the most insignificant monticules, and also the *bocche* and *boccarelle*, from which lava or fire has issued. If these be included, no doubt the above numbers are not exaggerations. The only large and important minor cone which has been raised during the historical period is the double mountain known as Monti Rossi, from the red color of the cinders which compose it. This was raised from the plain of Nicolosi during the eruption of 1669; it is 450 feet high, and two miles in circumference at the base. In a line between the Monti Rossi and the great crater 33 of the more important minor cones may be counted, and Captain Smyth was able to discern 50 from an elevated position on the mountain. Many of them are covered with vegetation, as the names Monte Faggi, Monte Ilice, Monte Zappini, indicate. In many instances the names have not been happily chosen, and several cones in different parts of the mountain bear the same name: Monte Arso, Monte Nero, Monte Rosso, Monte Frumento, are the most common of these duplicates.

Ascent of the Mountain.—The best period for making the ascent of Etna is between June and September, after the melting of the winter snows, and before the falling of the autumnal rains. In winter there are frequently nine or ten miles of snow stretching from the summit downwards, the paths are obliterated, and the guides sometimes refuse to accompany travellers. Moreover violent storms often rage in the upper regions of the mountain, and the wind acquires a force which it is difficult to withstand, and is at the same time piercingly cold. The writer of this article made the ascent of the mountain in the month of August, 1877, accompanied by a courier and a guide. The weather was fine and bright, and there had been no rain for more than three months. The temperature in the shade at Catania, and generally along the eastern coast of Sicily, was a mean of 82° Fahr. The party left Catania soon after mid-day, and drove to Nicolosi, 12 miles distant, and 2288 feet above the sea. The road for some distance lay through a very fertile district; on both sides there were corn-fields and vineyards, and gardens of orange and lemon trees, figs and almonds, growing in the decomposed lava. The road passes through several small villages,—Pasquali, Gravina, and Mascalucia—the last a town of 4000 inhabitants. Soon after this the Monti Rossi are seen apparently close at hand, the village of Torre di Grifo is passed, and the road then enters a nearly barren district, covered with the lava of 1537. The only prominent vegetation is a peculiar tall broom (*Genista Etnensis*), which flourishes here. Nicolosi was reached at half-past 4 o'clock, and after dinner in the one room of the very primitive inn, a start was made for the summit at 6 o'clock. For a short distance above Nicolosi stunted vines are seen growing in black ashes, but these soon give way to a large tract covered with lava and ashes, with here and there patches of broom. At half-past eight o'clock P.M. the temperature was 66° Fahr. About 9 o'clock the *Casa del Bosco* (4216 feet) was reached, at the foot of Monte Rinazzi, a small house in which several men live who have charge of the forest. After an hour's rest, the ascent of the higher regions was commenced, a great-coat and a double waistcoat being put on as a protection against the increasing cold. The air was extraordinarily still at this time; the flame of a candle placed near the open door of the Casa del Bosco did not flicker. The ascent from this point led through forests of pollard oaks, in which it was quite impossible to see either a path or any obstacles which might lie in one's way. The guide carried a lantern, and the mules seemed well accustomed to the route. At about 6300 feet above the sea the *Regione Deserta* was entered, a lifeless waste of black sand, ashes, and lava; the ascent now became more steep, and the air was bitterly cold. There was no moon, but the stars shone in extraordinary numbers and with wonderful brilliancy, sparkling like particles of white-hot steel. The Milky Way gleamed like a path of fire, and meteors flashed across the sky in such numbers as to baffle any attempt to count them. The vault of heaven seemed to be much nearer than when seen from the earth, and also more flat, and as if only a short distance overhead, and some of the brighter stars appeared to be hanging down from the sky. The idea of erecting an observatory on Mount Etna was brought forward last year, when Professor Tacchini, the astronomer-royal at Palermo, communicated a paper to the Accademia Gioenia, entitled *Della Convenienza ed utilita di erigere sull' Etna una stazione Astronomico-Meteorologico*, in which he refers to the extraordinary blueness of the sky as seen from the higher regions of Etna, and the appearance of the sun in a telescope, which is "whiter and more tranquil" than when seen from below; moreover the spectroscopic lines are defined with wonderful distinctness.

Toiling along the slopes of the *Regione Deserta*, at length the travellers reach the *Piano del Lago*, or Plain of the Lake, so called because a lake produced by the melting of the snows existed here till 1607, when it was filled up by lava. The air is now excessively cold, and a sharp wind is blowing. Progress is very slow, the soil consists of loose ashes, and the mules frequently stop. The guide maintains that the Casa Inglesi is quite near, but the stoppages become so frequent that it seems a long way off; at length it becomes necessary to dismount, and after a toilsome walk the small lava-built house called the Casa Inglesi is reached (1.30 A.M., temperature 40° Fahr.). It stands at a height of 9652 feet above the sea, near the base of the cone of the great crater. The Casa Inglesi takes its name from the fact that it was erected by the English officers stationed in Sicily in 1811. It has suffered severely from time to time from the pressure of snow, and from earthquakes, but it was thoroughly repaired in 1862, on the occasion of the visit of Prince Humbert, and is now in tolerable preservation. At 3 A.M. the Casa Inglesi is left for the summit of the great crater, 1200 feet above, in order to be in time to witness the sunrise. The road lay for a short distance over the upper portion of the Piano del Lago, and the walking was very difficult. The brighter stars had disappeared, and it was much darker than it had been some hours earlier. The guide led the way with a lantern. The ascent of the cone was a very stiff piece of work. It consists of loose ashes and blocks of lava, and it slopes at an angle of "45° or more," according to one writer, and of 33°, according to another. Probably the slope varies on different sides of the cone; on the side the ascent described was made the 45° certainly seems the more probable. Fortunately there was no strong wind, and no experience of the sickness of which travellers constantly complain in the rarefied air of the summit. The highest point was reached at 4.30 A.M., temperature 47° Fahr. Steam and sulphurous acid issued from the ground, and the cinders were so hot in some places that it was necessary to choose a cool place to sit down on. A thermometer inserted just beneath the soil from which steam issued registered 182° Fahr. Nearly all the stars had now faded away. The vault of heaven was a pale blue, becoming a darker and darker gray towards the west, where it was nearly black. Just before sunrise the sky had the appearance of an enormous arched spectrum extremely extended at the blue end. Above the place where the sun would presently appear there was a brilliant red, shading off in the direction of the zenith to orange and yellow; the latter was succeeded by pale green, this by a long stretch of pale blue, then darker blue, and dark gray, ending opposite to the rising sun with black. This effect was quite distinct; it lasted some minutes, and was very remarkable. It was succeeded by the usual rayed appearance of the rising sun, and at ten minutes to 5 o'clock the upper limb of the sun was seen above the mountains of Calabria. Examined by the spectroscope, the Fraunhofer lines were extremely distinct, particularly two lines near the red end of the spectrum. The top of the mountain was now illuminated, while all below was in comparative darkness, and a light mist floated over the lower regions. The party was so fortunate as to witness a phenomenon which is not always visible, viz., the projection of the shadow of the mountain across the island, a hundred miles away. The shadow appeared to be vertically suspended in space, at or beyond Palermo, and to be resting on a slightly misty atmosphere; it gradually sank until it reached the surface of the island, and as the sun rose, the shadow of course approached nearer and nearer to the base of the mountain. In a short time the flood of light destroyed the fine effects of light and shadow which were at first visible. The mountains of Calabria appeared very close; the east coast of Sicily could be traced until it ended at Cape Passaro and turned to the west, forming the southern boundary of the island, while to the west distant mountains appeared.

The crater was then examined,—a vast abyss nearly 1000 feet in depth, shut in by precipitous sides. Its dimensions vary, but it is now between two and three miles in circumference. Sometimes it is nearly full of lava, at other times it appears to be bottomless. At the present time it is like an inverted cone; its sides are covered with incrustations of sulphur and ammonia salts, and jets of steam perpetually issue from crevices in its sides. Near the summit was found a deposit several inches in thickness of a white substance, apparently lava decomposed by the hot effluent gases. Hydrochloric acid is said to frequently issue from the crater; the most abundant gases appeared to be sulphurous acid and steam. The interior of the crater reminds one in many respects of the Solfatara near Puzzuoli. During the descent from the cone various specimens of ash and cinder were collected—some red, others black and very vesicular, others highly crystalline, some pale pink. The steep slope of the cone was well shown by the fact that although the surface is either extremely rugged owing to the accumulation of masses of lava, or soft and yielding on account of the accumulation of cinders, a large mass of lava, set rolling near the summit, rushes down with increasing velocity until it bounds off to the plain below.

A striking feature presented during the descent from the mountain was the apparent nearness of the minor cones below, and of the villages at the base of the mountain. The latter seemed to be painted on a vertical wall, and although from ten to fifteen miles distant, they appeared almost within a stone's throw. This curious effect, which has often been observed before, is due to atmospheric refraction.

The different specimens of lava were found to present a wonderful similarity of structure and composition. The main constituents are olivine, magnetite, and felspar. The crystals of the latter are much larger in some specimens than in others. Sometimes olivine prevails, sometimes felspar. A specimen of lava of 1535 found near Borello was ground until it was sufficiently transparent to be examined under the microscope by polarized light. It was found to contain good crystals of augite and olivine, and well-striated labradorite and magnetite.

Eruptions.—A list of all the eruptions of Etna from the earliest times, has been given by several writers, notably by Ferrara in his *Descrizione dell' Etna*, and by Gemellaro.

The first eruption within the historical period probably happened in the 7th century B.C.; the second occurred in the time of Pythagoras. The third eruption, which occurred in 477 B.C., is mentioned by Thucydides, and it must be the eruption to which Pindar and Æschylus allude. An eruption mentioned by Thucydides occurred in the year 426 B.C. An outburst of lava took place from Monte di Mojo, the most northerly of the minor cones of Etna, in 396 B.C., and following the course of the river Acesines (now the Alcantara) entered the sea near the site of the Greek colony of Naxos (now Capo di Schiso). We have no record of any further eruption for 256 years, viz., till the year 140 B.C. Six years later an eruption occurred, according to Orosius and Julius Obsequens; and Fulvius Flaccus and the same authorities mention an eruption in the year 126 B.C. Four years later Katana was nearly destroyed by a new eruption, 122 B.C. An eruption, of which we possess no details, occurred during the civil war between Cæsar and Pompey, 49 B.C. Livy speaks of an eruption and earthquake which took place (43 B.C.) shortly before the death of Cæsar, which it was believed to portend. In 38 B.C. and 32 B.C. eruptions occurred. The next eruption of which we hear is that mentioned by Suetonius in his life of Caligula. This was in 40 A.D. An eruption is stated to have occurred in 72 A.D. after which Etna was quiescent for nearly two centuries, but in the year 253, in the reign of the emperor Decius, a violent eruption lasting 9 days occurred. According to Carrera and Photius, an eruption occurred in the year 420. We now find no further record for nearly 400 years. Geoffrey of Viterbo states that an eruption occurred in 812, when Charlemagne was in Messina. After another long interval, in this case of more than three centuries and a half, the mountain again entered into eruption, In February, 1169, one of the most disastrous eruptions on record occurred. A violent earthquake, which was felt as far as Reggio, destroyed Catania in the course of a few minutes, burying 15,000 persons beneath the ruins. It was the vigil of the feast of St. Agatha, and the cathedral of Catania was crowded with people, who were all buried beneath the ruins, together with the bishops and forty-four Benedictine monks. The side of the cone of the great crater towards Taormina, fell into the crater. According to Nicolà Speziale, there was a great eruption from the eastern side of the mountain in 1181. Lava descended from the eastern side of the mountain in 1285; in 1329 Nicolà Speziale was in Catania, and he witnessed a very violent eruption, of which he has left us an account. On the evening of June the 28th, about the hour of vespers, Etna was strongly convulsed, terrible noises were emitted, and flames issued from the south side of the mountain. A new crater, *Monte Lepre*, opened near the Val del Bue, above the rock of Musarra, and emitted large quantities of dense black smoke. Soon afterwards a torrent of lava poured from the crater, and red-hot masses of rock were projected into the air. Four years after the last eruption, it is recorded by Silvaggio that a fresh outburst took place. A manuscript preserved in the archives of the cathedral of Catania mentions an eruption which occurred on the 6th of August, 1371, which caused the destruction of numerous olive groves near the city. An eruption which lasted for twelve days commenced in November, 1408. A violent earthquake in 1444 caused the cone of the mountain to fall into the great crater. An eruption of short duration, of which we have no details, occurred in 1447. After this Etna was quiescent for 89 years. Cardinal Bembo and Fazzello mention an eruption which occurred towards the close of the 15th century. In March, 1536, a quantity of lava issued from the great crater, and several new apertures opened near the summit of the mountain and emitted lava. A year later, in May, 1537, a fresh outburst occurred. A number of new mouths were opened on the south slope of the mountain near La Fontanelle, and a quantity of lava was emitted, which flowed in the direction of Catania, destroying a part of Nicolosi, and St. Antonio. In four days the lava had run fifteen miles. The cone of the great crater suddenly fell in, so as to become level with the Piano del Lago. The height of the mountain was thus diminished by 320 feet. Three new craters opened in November, 1566, on the north-east slope of the mountain. In 1579, 1603, 1607, 1610, 1614, and 1619, unimportant eruptions occurred. In February, 1633, Nicolosi was partially destroyed by a violent earthquake, and in the following December earthquakes became frequent around the mountain. In 1646 a new mouth opened on the north-east side, and five years later several new mouths opened on the west side of the mountain, and poured out vast volumes of lava, which threatened to overwhelm Bronte. We have a more detailed account of the eruption of 1669 than of any previous eruption. It was observed by many men of different nations, and we find accounts of it in the *Philosophical Transactions*, and in several separate narratives in French and Italian. Perhaps the most accurate and complete description is that given by Alfonso Borelli, professor of mathematics in Catania. The eruption was in every respect one of the most terrible on record. On the 8th of March the sun was obscured, and a whirlwind blew over the face of the mountain; at the same time earthquakes were felt, and they continued to increase in violence for three days, at the end of which Nicolosi was converted into a heap of ruins. On the morning of the 11th a fissure nearly 12 miles in length opened in the side of the mountain, and extended from the Piano di St. Leo to Monte Frumento, a mile from the summit. The fissure was only six feet wide, but it seemed to be of unknown depth, and a bright light proceeded from it. Six mouths opened in a line with the principal fissure, and emitted vast volumes of smoke, accompanied by low bellowing, which could be heard 40 miles off. Towards the close of the day a crater opened about a mile below the others, and ejected red-hot stones to a considerable distance, and afterwards sand and ashes, which covered the country for a distance of 60 miles. The new crater soon vomited forth a torrent of lava, which presented a front of 2 miles. It encircled Monpilieri, and afterwards flowed towards Belpasso, a town of 8000 inhabitants, which was speedily destroyed. Seven mouths of fire opened around the new crater, and in three days united with it, forming one large crater 800 feet in diameter. The torrent of lava had continued to flow, and it destroyed the town of Mascalucia on the 23d of March. On the same day the crater cast up great quantities of sand, ashes, and scoriæ, and formed above itself the great double-coned hill called *Monti Rossi*, from the red color of the ashes of which it is mainly composed. On the 25th very violent earthquakes occurred, and the cone of the great central crater was shaken down into the crater, for the fifth time since the first century A.D. The original current of lava had divided into three streams, one of which destroyed San Pietro, the second Camporotondo, and the third the lands about Mascalucia, and afterwards the village of Misterbianco. Fourteen villages were afterwards destroyed, and the lava made its way towards Catania. At Albanello, two miles from the city, it undermined a hill covered with corn fields, and carried it forward a considerable distance; a vineyard was also seen to be floating on its fiery surface. When the lava reached the walls of Catania it accumulated without progression, until it rose to the top of the wall, 60 feet in height, and it then fell over in a fiery cascade, and overwhelmed a part of the city. Another portion of the same stream threw down 120 feet of the wall, and flowed through the city. On the 23d of April the lava reached the sea, which it entered as a stream 600 yards broad and 40 feet deep. The stream had moved at the rate of 13 miles in twenty days, but as it cooled it moved less quickly, and during the last 23 days of its course it only moved two miles. On reaching the sea the water of course began to boil violently, and clouds of steam arose, carrying with them particles of scoriæ. The volume of lava emitted during this eruption amounted to many millions of cubic feet. Ferrara considers that the length of the stream was at least 15 miles, while its average width was between 2 and 3 miles, so that it covered at least 40 square miles of surface.

For a few years after this terrible eruption Etna was quiescent, but in 1682 a new mouth opened on the east side of the mountain, and lava issued from it and rushed down the precipices of the Val del Bue. In 1688 a torrent of lava burst from an opening in the great cone, and in the following year lava was emitted from a mouth in the Val del Bue. Early in January, 1693, clouds of black smoke were poured from the great crater, and loud noises, resembling the discharge of artillery, were heard. A violent earthquake succeeded, and Catania was shaken to the ground, burying 18,000 of its inhabitants. It is said that in all fifty cities and towns were destroyed in Sicily, together with from 60,000 to 100,000 inhabitants. Lava was emitted from the crater, the cone of which was lowered by the eruption. In the following year Etna again entered into eruption. In March, 1702, three mouths opened in the Contrada del Trifoglietto, near the head of the Val del Bue. In 1723, 1732, 1735, 1744, and 1747 slight eruptions occurred. Early in the year 1755 Etna began to show signs of disturbance; a great column of black smoke issued from the crater, from which forked lightning was frequently emitted. Loud detonations were heard, and two streams of lava issued from the crater. A new mouth opened near Rocca di Musarra in the Val del Bue, four miles from the summit, and a quantity of lava was ejected from it. An extraordinary flood of water descended from the Val del Bue, carrying all before it, and strewing its path with large blocks. Recupero estimated the volume of water at 16,000,000 cubic feet, probably a greater amount than could be furnished by the sudden melting of all the winter's snow on the mountain. It formed a channel 2 miles broad, and in some places thirty-four feet deep, and it flowed at the rate of a mile in a minute and a half during the first twelve miles of its course. Lyell considers that the flood was probably produced by the melting not only of the winter's snow, but also of older layers of ice, which were suddenly liquefied by the permeation of hot steam and lava, and which had been previously preserved from melting by a deposit of sand and ashes, as in the case of the ancient glacier found near the summit of the mountain in 1828. In November, 1758, a smart shock of earthquake caused the cone of the great crater to fall in, but no eruption occurred at the time. In 1759, 1763, 1766, and 1780 eruptions occurred, and on the 18th of May in 1780 a fissure opened on the south-west side of the mountain, and extended from the base of the great crater for seven miles, terminating in a new mouth, from which a stream of lava emanated. This encountered the cone of Palmintelli in its course, and separated into two branches, each of which was about 4000 feet wide. Other mouths opened later in the year, and emitted larger quantities of lava, while in 1781 and 1787 there were slight eruptions. Five years afterwards a fresh outburst occurred; earthquakes were prevalent, and vast volumes of smoke were carried out to sea, seeming to form a gigantic bridge between Sicily and Africa. A torrent of lava flowed towards Adernò, and a second flowed into the Val del Bue as far as Zuccolaro. A pit called *La Cisterna*, forty feet in diameter, opened in the Piano del Lago near the great cone, and ejected smoke and masses of old lava saturated with water. Several mouths opened below the crater, and the country round about Zaffarana was desolated. In 1797, 1798, 1799, 1800, 1802, 1805, and 1808 slight eruptions occurred. In March, 1809, no less than twenty-one mouths of fire opened between the summit of the mountain and Castiglione, and two years afterwards more than thirty mouths opened in a line running eastwards from the summit for five miles. They ejected jets of fire, accompanied by much smoke. In 1819 five new mouths of fire opened near the scene of the eruption of 1811; three of these united into one large crater, and poured forth a quantity of lava into the Val del Bue. The lava flowed until it reached a nearly perpendicular precipice at the head of the valley of Calanna, over which it fell in a cascade, and being hardened by its descent, it was forced against the sides of the tufaceous rock at the bottom, so as to produce an extraordinary amount of abrasion, accompanied by clouds of dust, worn off by the friction. Mr. Scrope observed that the lava flowed at the rate of about a yard an hour nine months after its emission. Eruptions occurred in 1831, 1832, 1838, and 1842. Near the end of the following year, fifteen mouths of fire opened near the crater of 1832, at a height of 7000 feet above the sea. They began by discharging scoriæ and sand, and afterwards lava, which divided into three streams, the two outer of which soon came to a standstill, while the central stream continued to flow at the rapid rate of 180 feet a minute, the descent being an angle of 25°. The heat at a distance of 120 feet from the current was 90° F. A new crater opened just above Bronte, and discharged lava which threatened the town, but it fortunately encountered Monte Vittoria, and was diverted into another course. While a number of the inhabitants of Bronte were watching the progress of the lava, the front of the stream was suddenly blown out as by an explosion of gunpowder. In an instant red-hot masses were hurled in every direction, and a cloud of vapor enveloped everything. Thirty-six persons were killed on the spot, and twenty survived but a few hours. The great crater showed signs of disturbance, by emitting dense volumes of smoke, and loud bellowings, also quantities of volcanic dust saturated with hydrochloric acid, which destroyed the vegetation wherever it fell. A very violent eruption, which lasted more than nine months, commenced on the 26th of August, 1852. It was first witnessed by a party of six English tourists, who were ascending the mountain from Nicolosi in order to witness the sunrise from the summit. As they approached the Casa Inglesi, the crater commenced to give forth ashes and flames of fire. In a narrow defile they were met by a violent hurricane, which overthrew both the mules and the riders, and urged them toward the precipices of Val del Bue. They sheltered themselves beneath some masses of lava, when suddenly an earthquake shook the mountain, and the mules in terror fled away. They returned on foot towards daylight to Nicolosi, fortunately without having sustained injury. In the course of the night, many *bocche del fuoco* opened in that part of the Val del Bue called the Balzo di Trifoglietto, and a great fissure opened at the base of Giannicola Grande, and a crater was thrown up, from which for seventeen days showers of sand and scoriæ were ejected. During the next day a quantity of lava flowed down into the Val del Bue, branching off so that one stream flowed to the foot of Monte Finocchio, while the other flowed to Monte Calanna. The eruption continued with abated violence during the early months of 1853, and did not fully cease till May 27th. The entire mass of lava ejected is estimated to be equal to an area six miles long by two miles broad, with an average depth of about twelve feet. In October, 1864, frequent shocks of earthquake were felt by the dwellers on Etna. In January, 1865, clouds of smoke were emitted by the great crater, and roaring sounds were heard. On the night of the 30th a violent shock was felt on the north-east side of the mountain, and a mouth opened below Monte Frumento, from which lava was ejected. It flowed at a rate of about a mile a day, and ultimately divided into two streams. By March 10th the new mouths of fire had increased to seven in number, and they were all situated along a line stretching down from the summit. The three upper craters gave forth loud detonations three or four times a minute. Since 1865 the mountain has been in a quiescent state.

It will be seen from the foregoing account that there is a great similarity in the general character of the eruptions of Etna. Earthquakes presage the outburst; loud explosions are heard; rifts and *bocche del fuoco* open in the sides of the mountain; smoke, sand, ashes, and scoriæ are discharged; the action localizes itself in one or more craters; cinders are thrown out and accumulate around the crater in a conical form; ultimately lava rises through the new cone, frequently breaking down one side of it where there is least resistance, and flowing over the surrounding country. Then the eruption is at an end. Out of the 78 eruptions mentioned above, a comparatively small number have been of extreme violence, while many have been of a slight and harmless character.

According to Lyell, Etna is rather older than Vesuvius,—perhaps of the same geological age as the Norwich Crag. At Trezza, on the eastern base of the mountain, basaltic rocks occur associated with fossiliferous Pliocene clays. The earliest eruptions of Etna are older than the Glacial period in Central and Northern Europe. If all the minor cones and monticules could be stripped from the mountain, the diminution of bulk would be extremely slight. Lyell concludes that, although no approximation can be given of the age of Etna, "its foundations were laid in the sea in the newer Pliocene period." From the slope of the strata from one central point in the Val del Bue he further concludes that there once existed a second great crater of permanent eruption.

Such are the principal facts in the history of a volcano, justly called *famoso, immenso, terribile,* which has excited the wonder of all nations in all ages of the history of the world. (G. F. R.)

ETON, a village in Buckinghamshire, is situated on the left bank of the Thames, 21 miles W.S.W. of London, and is connected with Windsor on the opposite bank of the river by a cast-iron bridge erected in 1824. Eton is chiefly celebrated for its college, founded by Henry VI. in 1441, and endowed mainly from the revenues of the alien priories which were suppressed by Henry V. By Edward IV. its possessions were considerably curtailed; but on account of benefactions and the rise in the value of property, its annual income has gradually increased from £652 in the year 1506 till it now exceeds £20,000. The original foundation consisted of a provost, 10 priests, 4 clerks, 6 choristers, a schoolmaster, 25 poor and indigent scholars, and the same number of poor men or beadsmen. In 1443 the number of scholars was increased to 70, and the number of beadsmen reduced to 13. Until lately the government of the college was in the hands of the provost and fellows; but in 1870 the commissioners authorized by the Act of Parliament of 1868 appointed the "new governing body" of Eton, to consist of the provost of Eton, the provost of King's College, Cambridge, 5 representatives nominated respectively by the university of Oxford, the university of Cambridge, the Royal Society, the lord chief justice, and the masters, and 4 representatives chosen by the rest of the governing body. By this governing body the foundation was in 1872 made to consist of a provost and 10 fellows (not priests, but merely the other members of the governing body other than the provost), a headmaster of the school, and a lower master, at least 70 scholars, and not more than two chaplains or conducts. Originally it was necessary that the scholars should be born in England, of lawfully married parents, and be between eight and sixteen years of age; but according to the statutes of 1872, the scholarships are now open to all boys who are British subjects, and between twelve and fifteen years of age. A number of foundation scholarships for King's College, Cambridge, are open for competition amongst the boys; and there are besides several valuable extra scholarships and exhibitions, most of which are tenable only at Cambridge, some at Oxford, and some at either university. Besides the scholars of the foundation, Eton College is attended by about 850 scholars, who are either boarded with the masters or reside in private houses, and are called "oppidans." The total expenses of a boy educated as an oppidan average £200 a year. At one time the course of instruction was almost wholly classical; and although there were masters for other subjects, these were unconnected with the general business of the school, and were attended at extra hours. But in 1851 mathematics was incorporated into the curriculum of the school, and in 1869 physical science was introduced as a regular subject. The teachers of modern languages, of mathematics, and of physical science have now the same status, in regard to authority in and out of school, as the teachers of Latin and Greek. Among the celebrated men educated at Eton may be mentioned Sir Robert Walpole, Harley earl of Oxford, Lord Bolingbroke, Earl Camden, the famous Earl of Chatham, the Hon. Robert Boyle, Lord Lyttelton, Gray, Shelley, Horace Walpole, West, Waller, Fox, Canning, the marquis of Wellesley, Hallam the historian, the duke of Wellington, Dean Milman, and the earl of Derby. The singular custom termed the *montem*, which was observed here triennially on Whit-Tuesday, has now been abolished. The last celebration of it took place in 1844. It consisted of a procession of the boys in a kind of military order, with flags and music, headed by their "captain," to a small mound called Salt Hill, near the Bath road, where they levied contributions, or "salt," from the passers-by and spectators. The sum collected sometimes exceeded £1000,—the surplus, after deducting certain expenses, becoming the property of the "captain of the school. The building of Eton College was commenced in 1441, and the school was opened in 1442; but the whole original structure was not completed till fifty years afterwards. A new wing was completed in 1846; another block of buildings, containing 15 class-rooms, a music room, and an observatory, was built in 1861; these have been subsequently enlarged, and since the incorporation of physical science into the course of studies, an admirable chemical laboratory has been erected. The older buildings consist of two quadrangles, built partly of freestone but chiefly of brick. The outer quadrangle, or schoolyard, is inclosed by the chapel, schools, dormitories, and masters' chambers, and has in its centre a bronze statue of the royal founder. The buildings inclosing the inner or lesser quadrangle contain the residence of the fellows, the library, hall, and various offices. The chapel, on the south side of the outer court, is a fine Gothic edifice, containing some interesting monuments, among which is one to Sir Henry Wotton, who was long provost of the college; and at the west end of the ante-chapel is a fine marble statue of the founder in his royal robes, by Bacon. The chapel has lately been beautified and decorated, and a number of stained-glass windows have been introduced. The library contains a curious and valuable collection of books, a collection of Oriental and Egyptian manuscripts, and some beautifully illuminated missals. There is also a large library for the use of the boys. From the foundation of Eton College the college chapel was used as the parish church until 1854, when a handsome chapel-of-ease was erected at the cost of £8000. With the secularization of the college, the parish of Eton was in 1875 erected into an independent vicarage with the former chapel-of-ease as its parish church. In 1871 the population of the local board district of Eton (exclusive of the Eton boys) was 2806; of the parish, 3261.

Lyte, M.A. (1875); *Memoirs of Celebrated Etonians*, by J. Heneage Jesse (1875); and *The Eton Portrait Gallery*, by a Barrister of the Inner Temple (1875).

Early inhabitants.

ETRURIA. When or by what road the Rasena (Etrusci) reached their permanent seats in Etruria proper is by no means certain, though from the fact of their principal towns being well inland, from the tradition of their having been previously settled in Umbria, from the survival of their peculiar language down to late times among a people of the Rhætian Alps, and from the discovery of works of art in this district corresponding with the earliest Etruscan remains, there would seem to be considerable probability in the theory of their first settlement in Italy having been about the mouth of the Po, whence their progress would be through Umbria and across the Apennines. At the same time, it is to be remembered that, though "Rasena" was the national name of this people, yet there is strong evidence for supposing that the nationality, as we know it under the classical names of Etrusci or Tyrrheni (Τυῤῥηνοί, Τυρσηνοί), included another race which, if not nearly allied to the Greeks, had a singularly similar disposition towards the arts, such as it is hardly possible the original Rasena could have brought with them directly from the north. It would account for this other race, if we could accept the tradition (Herodotus, i. 94, Strabo, v. 220) of a body of Lydians having landed in Umbria and colonized Etruria, naming it after their leader Tyrsenus. This Lydian origin was accepted by the Etruscans themselves in late times (Tacitus, *Ann.*, i. iv. 55), and many have seen a confirmation of it in the similarity of the tombs and *tumuli* existing in both countries, and in the records of a singular community between them in such matters as music, games, and costume.[1] Yet a native historian of Lydia (Xanthus) said nothing of the emigration from that country, and Dionysius, who cites him, maintained that the language spoken in Etruria had nothing in common with that of Lydia. The legend of Herodotus is an attempt to explain the name of "Tyrrhenia" as applied by the Greeks to Etruria, owing, doubtless, to its being largely inhabited by members of that same Tyrrhenian race which was found on the coast of Asia Minor and in Thrace, which people Thucydides (iv. 109) identifies with the Pelasgians, while Herodotus himself (i. 57) speaks of the Tyrrhenian town of Creston, by which he means Cortona in Etruria accord-

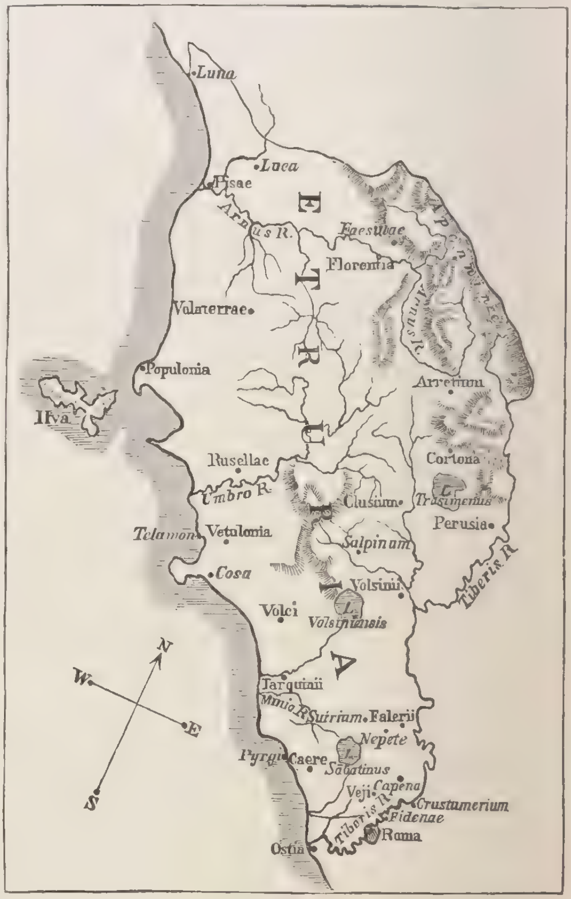


Chart of Etruria.

---

[1] Compare the tomb of Alyattes, still existing, and described by Herodotus (i. 93), with that of Cucumella at Vulci. Tradition said that the Lydian trumpet and the Phrygian double flute had been introduced into Rome from Etruria; that the *prætexta* or official robes, the eagle as a standard, and the game of dice, had been brought from Lydia to Etruria. Livy (iv. 17) tells how Lars Tolumnius determined, by means of dice, the fate of the Roman ambassadors who were sent to him at Veii (*cf.* Plutarch, *Vit. Rom.*, xxxiii.); and Festus (s. v. "Sardi") mentions the custom according to which, on occasions of sacrifice for victory at Rome, an old man dressed in purple was led to the Capitol, attended by a herald, who proclaimed "Sardians to be sold;" and they explain this custom as having survived from the sale of prisoners after the capture of Veii, which prisoners were Sardians, since Etruria had been colonized by Sardians. This custom, however, seems rather to have originated after the taking of Sardinia by Tib. Sempronius Gracchus.

ing to Dionysius, as Pelasgic. Another tradition asserted that Pelasgians from Thessaly had entered Italy from the Adriatic at Spina and founded Cortona. While then the Tyrrhenians and Pelasgians were practically the same people, it will be sufficient to use the former name to designate the apparently foreign element in the nationality of the Rasena. In historical times the chief seat of the Tyrrhenians outside of Etruria was in Thrace, where they worked the rich silver mines, and to judge from their coins (*e.g.*, those of the Edones and Bisaltæ) were gifted with much the same disposition towards fine art which is observed in Etruria. From this position in a northern region, and from the traditions of members of the same race having entered Italy from the north-east, it is not unreasonable to suppose that they may have gradually made their way round by land, and may, in fact, have joined the Rasena while they were yet in their settlements at the mouth of the Po. So complete a blending of two races as appears in the Etrusci could scarcely take place unless the original contact had been during a primitive stage of civilization. No doubt there were other Tyrrhenians besides those of Thrace. There were those who were known chiefly as pirates, or as successful in seafaring, and from the circumstance of Cære, which previously had the Tyrrhenian name of Agylla, having been near the coast, it would seem as if part at least of the Tyrrhenians had entered Etruria by sea on the west coast.

Cities.

It is common enough to find mention of the twelve cities of Etruria, but nowhere are their respective names recorded. The probability is that in process of time this or that city fell out of the league, and was replaced by towns of more recent growth, till in the end there were at least seventeen presumable claimants for the title of one of the twelve. This is the case as regards Etruria proper, but there was a time when similar leagues appear to have existed among the Etruscan cities in the neighborhood of the Po (Etruria Circumpadana), and again among those of Campania. As to the confederation of twelve cities in Etruria proper, and the political principles on which it was founded, nothing is positively known, except that the principles were essentially aristocratic, much as in early Rome under the kings. The kings were elective for life, and were held in check by the *principes* or Lucumos, who represented the real power of each state. In national enterprises one of the kings was chosen for supreme command, having a lictor from each city. The surroundings of official dignity found afterwards in Rome, the purple robe, the prætexta, the twelve lictors and fasces, the apparitores, the curule chair, and triumphal processions, were derived from Etruria, and indicate the nature of her constitution. The representatives met at the temple of Voltumna, the locality of which is not known (Livy, iv. 23), apparently in spring; but it would seem that, in fact, the confederation was far from strictly maintained, at any rate in the matter of external policy. For internal affairs they had certain books (*libri disciplinæ Etruscæ*) in which they were instructed as to the founding and consecration of public or religious buildings, the distribution of the people into tribes, curiæ, and centuriæ, the constitution of armies, and the management of everything pertaining to peace or war (Festus, s. v. "Rituales"). These books were divided into three sections, the third, *libri rituales*, being those to which reference has just been made. The other two were devoted to divination, an art in which the Etruscans surpassed all other nations. The first part was the *libri haruspicini*, containing instructions for divining the will of the gods from abnormal conditions observed in the entrails of animals slain in sacrifice, or from unusual natural phenomena. The second part was the *libri fulgurales*, treating of divination from lightning. By such means the gods were believed to indicate their wishes towards men, and, indeed, had declared so much through the divine seer, Tages, a miraculous dwarf whom a laborer ploughing one day found in his furrow. Though then but a boy, Tages had gray hair, and was wise as if of a great age. His sayings, delivered always in verse, like oracles, were taken down by Tarchon, and formed the books in question. Tarchon was the founder of Tarquinii, and from this town proceeded the other cities and their organization. Such is the legend, and in the early history of Etruria we have, as elsewhere, only legend, known mainly through the annals of Rome, which, when they go back to a period before the introduction of writing (apparently in the 7th century, B.C.) must be largely imaginary, and even long after this, are highly colored.

Veii.

First in importance among the Etruscan cities was *Veii*, the site of which has been identified at Isola Farnese, about 11 miles from Rome, its great rival and ultimate victor. Strong by its natural position on a high cliff, and fortified with massive walls, rich in its own territory, and commanding the assistance of its subject towns, Sabata, Sutrium, Nepete, and Capena, it maintained an almost constant state of war with Rome from the legendary times of Romulus down to its capture by Camillus, 396 B.C., after which, by a decree of the Roman senate, it was forbidden to be inhabited (Livy, v. 6). The spoils then carried away indicated its wealth, and doubtless this, together with other measures then taken, led to the desolation which now reigns on the site. Of the 14 recorded wars with Rome, the most memorable were—the 7th (509 B.C.), in which, to replace Tarquinius Superbus on the throne of that city, Porsena of Clusium marched to its gates, though in a previous battle the Etruscans had been declared vanquished by a mysterious voice in the night, because they had lost one man more than the Romans; the 9th and 10th (482–476 B.C.), in which occurred the treacherous massacre of the Fabii, who, with their clients, to the number, it is said, of 4000, had volunteered to hold Veii in check from their camp on the Cremera; the 12th, in which their king Tolumnius was slain, and the 14th, in which the Romans, to whose gates the Veientes had so often carried terror, laid siege to Veii, and in the tenth year took it, as is said by the stratagem of a cuniculus or mine up through the rock of the citadel. Those who believe this story point out that Camillus may have obtained his idea from the *cuniculus* or outlet of the waters of the Alban lake, which also at this time was made to play a miraculous part. The waters of the lake were observed with alarm to be rising and threatening to overflow. The oracle at Delphi was consulted, and in consequence of its advice this outlet was made by the Romans in the space of a year (Livy, v. 15, 16).

Tarquinii.

Scarcely less important than Veii, and like it also undoubtedly one of the twelve cities, was *Tarquinii*, now Corneto, the queen of the Maremma, towards which Graviscæ seems to have served as the port by which its great trade was carried on. The story runs that among those who preferred exile to the tyranny of Cypselus in Corinth in the early part of the 7th century B.C. was a wealthy merchant, Demaratus, who, accompanied by certain artists with mythical names (Eucheir, Diopus, and Eugrammus), settled in Tarquinii, which it is to be presumed was then sufficiently advanced in civilization to offer prospects of comfort, and to have been known to the traders of Corinth at least. Demaratus married a lady of Tarquinii, and had a son Lucumo or Lucius, who, though rich, suffered from being looked down on as a foreigner, and, to escape this, migrated to Rome, where in time he rose to the highest office of king, under the title of Tarquinius Priscus, and compelled the submission of the whole of Etruria, the token of which was the insignia of the twelve fasces, representing the twelve cities. He was succeeded by Servius Tullius, or Mastarna, as the Etruscans called him, under whose rule Etruria revolted, but without final success. Then came Tarquinius Superbus and his expulsion from Rome, on which occasion Tarquinii and Veii sent an army to endeavor to reinstate him. In the battle which followed, Aruns Tarquinius and Junius Brutus the first consul fell by each other's hands. From this time Tarquinii was quiet for a century, till 397 B.C., when it joined Veii against Rome unsuccessfully, and thus revived a series of wars, in which, though generally worsted with severe loss, she yet maintained her independence down to the defeat at the Vadimonian lake, 283 B.C. Towards the close of the second Punic war, when the Etruscan cities had to furnish Scipio's fleet each with its staple commodity, Tarquinii supplied sail-cloth.

Cære.

Corn and other provisions were supplied by *Cære*, a town which, if less famous in war than the two already described, was better known in the arts of peace. No doubt, in the legendary age, when it was ruled by the cruel Mezentius (*Æneid*, viii. 482), it was sufficiently warlike, but in later times it rarely joined in the struggles against Rome, where, indeed, its people stood in high favor for having sheltered the Roman vestals and the Flamen Quirinalis from the Gauls (389 B.C.).

From the privileges enjoyed by the Cærites in Rome arose, it was said, the word "cærimonia." It is recorded to the honor of Cære that she abstained from the piracy common among coast towns in early times (Strabo, v. 220); and it is a proof both of her advancement in civilization and of her reputation among the Greeks that she had a treasury at Delphi, where it was known as the treasury of Agylla, such having been the original name of the city. How the change of name arose is accounted for (Strabo, v 220) with the ingenuity characteristic of ancient derivations. Agylla had been founded by Pelasgians from Thessaly, but was afterwards captured by the Tyrrhenians from Lydia (cf. *Æneid*, v. 479), who, having inquired the name of the town they were besieging, and having been answered by some one from the walls with a word which they took to be the Greek *χαῖρε*, adopted this as the new name of the city. Herodotus (i. 167) speaks of it as Agylla, and relates how it joined the Carthaginians against the Phocæans of Alalia in Corsica (about 534 B.C.), and, having carried away its share of the booty and of the prisoners, put the latter to death. Upon this followed a plague, as to which the Agyllæans consulted the oracle at Delphi, and were told in reply that the way to appease the Phocæans would be to institute public festivals of athletic games and horse-racing. The sea-port was Pyrgi, celebrated also for the wealth of its temple of Eileithyia, which Dionysius, the tyrant of Syracuse, ransacked (384 B.C.), taking from it 1000 talents, and spoils to the value of 500 talents more. As evidence of the high antiquity of the arts in Cære, there is the statement of Pliny (xxxv. 4–6), that paintings existed there older than the foundation of Rome. It was said to have been the last refuge of the Tarquins, and in confirmation of this is the modern discovery of a large sepulchre belonging to a family of that name, as seen from the numerous inscriptions in it. Little remains except *tumuli* and sepulchres, among which the most famous is that known as the Regulini-Galassi tomb, the masonry of which is Pelasgic in character.

Falerii.

In close political relationship to Veii, and probably reckoned as one of the twelve cities, though its population (the Falisci) was not purely Etruscan, was *Falerii*, originally on a high bare rock, but afterwards under Roman compulsion transferred to the broad plain which stretches to the Tiber, the Æquum Faliscum as it was called, to indicate the plain, not the justice of the people. The very ancient Fescennium seems to have been included in its territory. Trusting in its natural strength, Falerii vainly made light of the Roman siege conducted by Camillus (391 B.C.). It was on this occasion, as told by Livy (v. 27), that an official of Falerii, to whom was entrusted the education of the sons of the better class, led his pupils outside the city for their exercise as in times of peace, and by daily increasing the distance of their walks avoided suspicion, till at last he reached the Roman camp and offered to surrender the boys to Camillus, who, indignant at the treachery of the man, ordered him to be stripped, bound, and handed over to his pupils to be led back and punished. The habit of appointing an official of this kind is spoken of as a Greek one, and, in connection with the legendary foundation of Falerii by Halesus or Haliscus, a son of Agamemnon, together with the fact of its temple of Juno being the counterpart of the temple of that goddess at Argos, is taken as evidence of a strong Greek element in the town. Strabo (v. 226) quotes the opinion of some that the Falisci were not Tyrrhenians, but a distinct nationality.

Volci.

One of the twelve cities also was *Volci* (Vulci) apparently, though the historical notices of it are but few, and leave no impression of any great power. Yet its remains, as discovered in numerous sepulchres, show that it must have been an important city. Of these the tumulus of Cucumella, as it is now called, is remarkable not only for its size (200 feet in diameter, and 40 to 50 feet high still), but also for its general similarity to the tomb of Porsena at Clusium, of which we have only the description as quoted by Pliny (xxxvi. 13, 19), and to the tomb of Alyattes in Lydia. Up to 1830 this tomb at Vulci was encircled round the base with a massive wall, which is now gone. In the heart of the mound were discovered two loosely built towers, one of them square, the other conical, which perhaps may be fairly compared with the pillars in the tomb of Porsena and the *οὖροι* in that of Alyattes. From the other sepulchres of Vulci has been obtained a vast number of antiquities, not a few of which are of the first importance for the history of art in Etruria and will be afterwards referred to.

Volsinii.

Volsinii, called by the Etruscans Felsuna, as appears from its coinage, and now Bolsena, was one of the most powerful and warlike of the Etruscan states. The original site, it has been thought, was at Orvieto, which the Romans after a long and arduous siege destroyed, compelling the Volsinii to settle on the low ground at Bolsena.

Clusium.

Clusium (Chiusi), originally Camars (Livy, x. 25), had been founded by the Umbrians, but became one of the principal cities of Etruria, being apparently at the height of its fame under the rule of its king Porsena, who to reinstate Tarquinius Priscus made that march to Rome (505 B.C.), with which are associated the undying legends of Roman heroism in the persons of Horatius, Scævola, Clœlia, and Publicola (Livy, ii. 11–13). Before this we find Clusium joined with other Etruscan cities on the side of the Latins against Tarquinius Priscus. Afterwards it was the assistance given by Rome to Clusium which drew down the Gauls on the former in 389 B.C. At the close of the second Punic war Clusium furnished corn and fir for ship-building to the Roman fleet. Mention has been made of the tomb of Porsena said to have existed at Clusium. In one place labyrinthine passages have been found among the tombs, such as appear to correspond to one of the features in the description of that sepulchre.

Arretium.

Arretium (Arezzo) was one of the twelve cities, but famous chiefly in comparatively recent times. In 301 B.C. the citizens rose against the tyranny of their great family, the Cilnii, and drove them to exile in Rome, where their cause was taken up with this practical result, that a Roman army defeated the Arretines at Russellæ. Afterwards the city joined in league with the Gauls and Umbrians against Rome, but again was defeated. Next it was besieged by the Gauls. There is no record of its final submission to Rome. In the second Punic war it furnished corn, implements, and material of war for the Roman fleet. During the civil wars it took the side of Marius, and would in consequence have lost all rights but for the intercession of Cicero. The present site does not appear to be that of the ancient town. Of its walls, which were said to have been built of brick, there is no trace.

Cortona.

Conspicuous still for its stupendous walls and towers, commanding a high bare rock, is *Cortona*, where everything that remains is in harmony with the tradition of its extraordinary antiquity. Of other records there are scarcely any.

Perusia.

Like *Perusia* (Perugia) it had once been an Umbrian city, and like it also one of the twelve states of Etruria. Parts of the walls of Perusia remain, and many objects of great interest have been found on its site, none more precious, however, than the "Cippus of Perugia," with its long Etruscan inscription. Perusia comes first into notice arrayed against Fabius, who compelled her to sue for peace. In the following year she was again at war, and shared in the disaster at the Vadimonian lake. Other defeats followed, but not even that in which Fabius slew 4500 of her men, and took 1740 prisoners, was sufficient to reduce her to obedience to Rome, though that event followed not long after. In the second Punic war she supplied corn and fir to the Roman fleet. In the civil wars she took an active part, and when besieged by Octavius Cæsar yielded only to famine. A great fire followed, after which the city was rebuilt by Augustus. Even under the empire it maintained a position of importance.

Volaterræ.

Volaterræ, called Velathri on its coinage, and now Volterra, of which the massive walls from 4 to 5 miles in circuit still stand on a great bare height visible far round, appears to have been one of the twelve cities, notwithstanding the fact of its having taken part with the Latins against Tarquinius Priscus. Almost nothing, however, is known of its history except the record of a defeat (298 B.C.) inflicted by L. Cornelius Scipio (Livy, x. 12), the battle having raged all day till darkness set in. The Etruscans deserted their camp in the night. Though considerably inland, Volaterræ is cited as having supplied tackling and other gear for Scipio's fleet, from which it would appear that she had been maritime, trading probably in the main through the port of Populonia, which is said to have been colonized by her. Possibly also the island of Elba with its rich mines belonged to Volaterræ. Its territory was extensive. During the civil wars it took the side of Marius, and after a siege of two years had to surrender, and only for a time escaped having to receive a military colony through the exertions of Cicero. Besides the walls there remain still several sepulchres of great interest, in particular that of the Cæcinæ family, famous in Roman history, and the ruins of two dome-shaped chambers, resembling in their construction the so-called tomb of Agamemnon at Mycenæ. **Populonia.** *Populonia*, called *Pupluna* on its coins, furnished iron obtained from the mines of Elba for Scipio's fleet. During the civil war it was destroyed by Sulla. Parts of the walls of huge masonry remain. **Russellæ.** *Russellæ* (Roselle) still survives in its walls of colossal masonry, but otherwise is a wilderness. Its history is uneventful, except for the siege by the Romans (294 B.C.), when it lost 2000 as prisoners and as many more slain (Livy, x. 37). It furnished corn and fir for the fleet of Scipio. *Vetulonia* is given as one of the twelve cities, but little is known of it from records, and scarcely anything from remains, if, as appears to be the case, Mr. Dennis is right in identifying its site on the coast near Telamone, which he presumes would have been its port. *Pisæ*, on the coast, was said to have been founded by Tarchon as a barrier against the Ligurians. Luna and Luca were probably included in its territory. Of *Fæsulæ* the huge walls on an impregnable height still remain. In Roman times the inhabitants moved to the lower ground of Florence. At Cosa and Saturnia are remains of massive walls, and at the latter place a peculiar form of tomb, which seems to date from a very early and at any rate a rude age. *Salpenum* and *Aurinia* are mentioned also among the Etruscan cities. Outside of Etruria proper, but still claiming to be Etruscan towns, we have, in Etruria Circumpadana, *Felsini*, afterwards called *Bononia*, said to have been at the head of the league formed by this district, *Melpum, Mantua, Spina, Ravenna, Hatria*, and *Cupra*. In Campania again were the following cities which Etruria was said to have founded or sent colonists to, but without the effect of making them practically Etruscan towns:—*Capua, Nola, Pompeii, Herculaneum, Surrentum, Marcina, Salernum.*

Natural resources. These, then, are the towns of Etruria. In their records and in their ruins they survive as monuments of a life spent in extraordinary activity, and highly honored in death. No country has left such wealth in its tombs. Nowhere have such battlements endured till now. Nature must have largely aided the Etruscans with her fertility, where now she is either exuberant to the degree of being a wilderness or pestilential as in the Maremma. Evidence of its natural products has been seen in the corn, fir wood, and iron, supplied to the Roman fleet. Its rivers and lakes must have assisted agriculture ("sic fortis Etruria crevit," Virg., *Georg.*, ii. 533), on which the country appears to have relied even more than on commerce, since, with a large sea-coast, it had comparatively few ports. The exceeding unhealthiness of the coast district anciently as now may have had much to do with this result. Yet their commerce was such as to place the inhabitants in a position to make treaties with that powerful nation of traders the Carthaginians, as, for instance, in the mutual agreement that the latter should hold Sardinia while the Etruscans retained Corsica. To the Athenian expedition against Sicily in the Peloponnesian war Etruria sent three ships, probably more from enmity to Sicily than from friendship to the Athenians. Their success in piracy was too well known in early times. The greater part of the country is broken up by chains and ridges of hills. The supply of timber was large, and doubtless profitable, as were also the pastures, from which a considerable trade in cattle-rearing and wool-spinning was derived. The numerous lakes—Lacus Ciminius, Sabatinus, Vadimonius, Clusinus, Thrasymenus, and Volsinius with its basalt rocks—afforded extensive occupation in fishing as did the forests for hunting. Wine, largely produced, was nowhere so fine as at Luna. Flax and linen were grown at Falerii and Tarquinii. Besides iron and copper, there was a supply of silver and gold. The variegated marble of Luna was greatly prized. Volaterræ yielded alabaster, Arretium a clay peculiarly adapted for pottery, for which in later times it was celebrated. Tufa or travertine could be obtained in massive blocks from many places. There were numerous warm and sulphurous springs. The country had once been volcanic in many places, the extinct craters serving as basins for lakes. The most fertile and most highly cultivated districts were in the north at the foot of the Apennines, and along the upper valleys of the Arno and Tiber. The chief rivers were the Clanis, the Arnus (Arno), and the Umbro.

Customs. During the early period the natural resources of Etruria must have been severely drained by her wars with Rome. Afterwards, when she sank into dependence, there arose private wealth, and the individual Etruscan became *pinguis et obesus*, an expression which is abundantly verified by the portrait sculptures on their sarcophagi. Their extravagance in diet was a reproach, and in connection with this their habit of reclining at banquets, as constantly seen in their works of art, was remarked on as similar to that of the Greeks; while the presence on these occasions of women who joined in the toasts, contrary to the customs of the Greeks and the Italic nations, was pointed out as consistent with the origin of the Etruscans from Lydia, where no less indulgence was said to have been allowed to women, and where also, as in Etruria, it was very usual to trace descent from the maternal side. Etruscan dancers, who appear to have attended private as well as public ceremonies, were distinguished for the skill with which, without words, and only by action and gesture, they represented a story. Different from this may have been the armed dance, since it recalls that of the Salii in Rome, who accompanied their movements by songs of heroic deeds of old. Athletic contests, such as those of the Roman circus, together with displays of gladiatorial fights, were part of the amusements, and it seems almost certain that the latter form of excitement was derived by Rome from Etruria. The flute, trumpet, and *lituus* were the favorite musical instruments. Their literature consisted mainly of religious verses and national songs, of which, however, nothing is known. To these must be added the form of satyric songs which originated in Fescennium, a place belonging to Etruria. In science, especially in medicine, and in philosophy their knowledge was highly reputed. As regards time, they reckoned by lunar months, and appear to have had some principle of intercalation, to equalize the solar and the lunar year. The lapse of each year was recorded by driving a nail into the door of the temple of Nortia at Volsinii, a habit which passed over to Rome. The month was divided into weeks of eight days, the eighth being set apart for marketing and house affairs; the day began at noon. Next to years they counted by *sæcula*, each representing the longest life of the time, and reaching in some cases to 123 years, but with an average apparently of about 100 years. The Etruscan nation was to endure ten sæcula. The beginning of the 10th was announced in the year 44 B.C. The festivity of the Etruscans was accompanied by excess in personal ornaments and in dress; the toga picta, tunica palmata, the prætexta, the corona Etrusca, and the rich sandals which figured in Rome as insignia of office, had been introduced from Etruria, where also no doubt they served to mark the *principes* or *lucumones* as distinct from the mass of the people, to whose lot it is in the highest degree improbable that such luxury as has been spoken of could have fallen. Their food was pulse, which may have been sweeter at Volsinii from being ground in curiously contrived mills (*molæ versatiles*) of basalt (Pliny, xxxvi. 18, 29). Clientship, developed to the full in Rome, had first been proved practicable in Etruria, as was also the employment of slaves. The division of the people into three *tribus* and twelve *curiæ* at Mantua has been taken as representing the general principle of division, and this would seem to be confirmed by the tradition of the three names of Ramnes, Tities, and Luceres having been adopted for the Roman *tribus* from Etruria. To the books of discipline, by which public and private affairs were regulated, reference has already been made. There appears to have been also a fourth section of these books, *libri fatales*, dealing with common incidents. The interpretation of all these books and the conduct of such ceremonies as they prescribed belonged exclusively to the noble families, some of which had hereditary rights to the priesthood. In each state were always ten boys of such families undergoing instruction for this purpose. But besides the regular societies or colleges of Haruspices to which the Romans sent for aid when perplexed by serious portents, there were apparently others who obtained a vicarious living by ministering to the all-pervading superstition of the people. Instead of an oracle common to the whole nation as the Greeks had at Delphi, each state or city of Etruria had its own complicated machinery for discovering the will of the gods.

(See AUGURS.) Certain deities revealed their will by lightning, others otherwise.

Mythology.

The gods (*æsar*) were of two classes, the *Dii Consentes*, who directly managed the affairs of the world, and certain nameless deities above and controlling them in such a way as Fate is above Zeus in the *Iliad*. At the head of the former was Jupiter (called *Tinia* in Etruscan), with whom were associated Juno (*Uni*) and Minerva (*Menrfa*), forming a supremacy of three for the protection of states, as may be inferred from the legend of Tarquinius having adopted them as the three chief deities of Rome. Their functions, however, were in each case different from those of the corresponding divinities of Rome and Greece, Jupiter being at once ruler of all in peace, god of war, and source of fertility in the earth, while Juno similarly was worshipped as "regina" in Veii, as *curitis*, an armed goddess, at Falerii, and as associated with Vulcan at Perusia, thus taking the place of the Greek Aphrodite and representing fertility. Minerva, again, was winged besides being armed, had the functions of Fortuna or Fate, and from her symbol of the serpent was a deity of the powers of the earth. The Etruscan name of Venus was *Turan*, of Vulcan, *Sethlans*, of Bacchus, *Phuphluns*, of Mercury, *Turms*. Besides the other Greek deities who were in one way or another adopted into the Etruscan system, such as Apollo, Helios, Ares, Poseidon, Heracles, and the Dioscuri, a number of names have been handed down, some of which obviously designate gods of Latin or Sabine origin, while others may be synonyms of one and the same deity obtaining in different localities. The list includes Janus, Silvanus, Inuus, Saturnus, Summanus, Vejovis, Soranus, Mantus, Pales, Nortia, Feronia, Voltumna, Mania, Eileithyia, Horta, Ancharia, Fortuna, Ceres, and others. To these were attached numerous genii of various powers and functions. As ruler of the lower world was the grim god Mantus with his hammer, and his associates Mania, Charun, and the Furiæ. Among the Lares Familiares were included the shades of deceased persons. The Penates watched over household plenty and prosperity. A goddess of Fate who occurs frequently on the monuments is Lasa, probably a feminine derivative from Lar, ruler, as in Lars Porsena. From what combination of early races or from what promiscuous habit of adopting foreign deities, this complicated system arose cannot now be decided.

Architecture.

For these gods temples were necessary, but in no case have they survived. Yet from records it would seem that they differed from those of Greece in no essential particular except in the ground plan, which, instead of being much greater in length than in breadth, was nearly square, to be in conformity with the *templum* or arbitrary division of the heavens prescribed by the sacred books. The theatres have been more fortunate, as at Fiesole, where the massive ruins still show how in this form of construction also the Etruscans had been indebted to the Greeks. Of amphitheatres or circi there are no remains. There is, however, one form of construction in which they are allowed to have been first, that is the arch, as seen among other places best of all in the *Cloaca* of Rome, the building of which tradition regularly assigned to the Etruscans in the time of the Roman kings. How the perfect arch was developed may be seen from the apparent vaulting in the Regulini-Galassi tomb at Cervetri and elsewhere, a system of masonry which the Etruscans had in common with the builders of the so-called Tomb of Agamemnon at Mycenæ. The earliest tombs seem to be those in the form of a well, sunk in the ground and lined with stones, containing a vase with the ashes and burnt remains of the dress and ornaments of the deceased. In this early period cremation appears to have been the rule, if, indeed, it was not always more or less a favorite form of sepulture. Next we have two classes of tombs. First the *tumuli*, consisting of chambers encircled by a massive wall, and covered with a mound of earth corresponding to the tumulus of Alyattes in Lydia and other parts of Asia Minor, as well as to the Nuraghe of Sardinia. Of this general type doubtless was the tomb of Porsena at Clusium, in spite of the probably fantastic description of it already referred to. Its labyrinthine chambers have been identified. The tumulus of Cucumella at Vulci has also been mentioned. Then we have tombs hewn in the rock, sometimes including several chambers connected with each other, and frequently adorned, like those of Lycia, with architectural fronts as of small temples. In these chambers, were placed the sarcophagi and urns, for the most part richly sculptured, in general with subjects of design adapted from the Greeks, and having frequently on the lids reclining figures intended either as portraits or in some other way to represent the deceased, whose name and descent are painted on the front. In many cases the walls of these chambers are richly decorated with paintings, not exclusively but mostly reproducing scenes of festivity. The dead were accompanied in their resting-place by numerous presents of painted vases, armor, and other objects. As a rule a special district or cemetery was set apart for the dead, but how far it was laid out so as to correspond with the quarters of each town cannot now be determined. For the construction of the dwelling-houses and Tuscan architecture generally see ARCHITECTURE, vol. ii. p. 362.

Language.

[LANGUAGE.—By Etruscan is meant the language which was spoken by the Rasena in Etruria more or less during the last thousand years B.C. until it succumbed to the Latin. It was the predominant language of Campania also from 800 to 400 B.C., at which time it yielded to the Oscan. Soon after this, owing to the incursions of the Gauls, it lost its hold on what was apparently its oldest home in Italy, the valley of the Po, but continued to exist in a debased form in the time of Livy (v. 33) among certain peoples of the Alps, in particular among the Rhæti. To the ancients Etruscan sounded barbarous. Dionysius (i. 30) declared it to be related to no other language. Still there was a time when among the better class of Romans Etruscan was taught, just as afterwards was Greek (Livy, ix. 36). Its remains as preserved by writers are few and frequently misrepresented, including about 60 names of places, 28 rivers, several islands, hills, woods, and lakes. Of names of persons there are 7 prænomina, and 50 gentile names and cognomina together, a few names of deities, heroes, and mythical kings, 7 names of months, and about 30 glosses, mostly from Hesychius, Servius, and Festus, and in part very doubtful. Altogether there are a little over 200 words, and of these many are local names, and have obviously originated among peoples of the Ligurian, Umbrian, and Latin races conquered by the Etruscans. The Etruscan inscriptions discovered on antiquities up to the present time will be found in Fabretti's *Corpus Inscriptionum Italicarum*, with "Glossarium Italicum," Turin, 1867; "Primo Supplemento," 1872, "Sec. Suppl." 1874. The total number now reaches to about 5000, and increases yearly at the rate of 100 to 200. Unfortunately they include only 15 bi-linguals (Lat. and Etr.), and these are very short, containing almost nothing but names. Except the "Cippus of Perugia" found in 1822, which has 46 lines, Etruscan inscriptions are all short, there being for instance only five which have more than 20 words. Four-fifths of them are sepulchral, with the mere indication of names or relationship. A few names of towns have been preserved on coins, as also the numerals from 1 to 6, on a pair of ivory dice. Altogether there are about 200 words which appear not to be names.

Lepsius (*Inscript. Umbr. et Oscæ*, Leipsic, 1841) was the first to determine definitely the character of the Etruscan alphabet. Its companion and northern variants were pointed out by Mommsen (*Unteritalische Dialekte*, Leipsic, 1840), and according to those authorities it was derived from a Græco-Chalcidian prototype current on the west coast of Italy. In its common form it has the following 19 letters:—

a, c, e, v, z, h, θ, i, l, m, n, p, s′, r, s, t, u, χ, f.

Of these *c* is a *tenuis*, θ = th, χ = ch, s′ is soft, while the other letters have the usual force. Exceptionally ꓘ = *k* occurs as an archaic form of *c*; Φ = ϕ = ph, mostly in foreign words, and Λ = *m* (Umbrian). The mediæ *b*, *g*, *d*, and the vowel *o*, though they often occur in words handed down by writers as Etruscan, are never found in the inscriptions. (For other peculiarities see Fabretti, "Osservazioni Paleografiche," *Corp. Inscr. Ital. Pr. Suppl.*, pp. 145–252.)

The first who attempted to explain the Etruscan inscriptions was Phil. Buonarroti (*Explic. et Conject. ad Monum. Oper. Dempster*, Flor., 1726). He was followed by Giov. Batt. Passeri (*Paralipomena in Th. Dempster*, Lucca, 1767), who sought to prove them to be in an Italic language,—in fact, a dialect of the Latin. This opinion has maintained its ground with many, and only quite recently we find the great work of Corssen (*Die Sprache der Etrusker*, Leipsic, 1874–75) devoted to the elaboration of a strictly scientific basis for it. On the other hand, Ottfried Müller (*Die Etruscer*, Breslau, 1828) had observed certain distinctly foreign elements in the language, and had pointed them out clearly enough, without, however, venturing upon any conjecture as to their source. His views, though adopted by Niebuhr, Mommsen, and Aufrecht, have not satisfied others less skilled in these inquiries, who have endeavored to trace the Etruscan to a Celtic, Germanic, Slavic, Albanian, Basque, Semitic, and lastly a Turanian origin (Isaac Taylor, *Etruscan Researches*, London, 1874). These attempts have all failed, and Müller's attitude of reserve appears to be decidedly the best under the circumstances. (See W. Deecke, *Corssen und die Sprache der Etruscer*, Stuttgart, 1875; *Etruscische Forschungen*, 1875–76; and the new edition of O. Müller's *Die Etruscer*, Stuttgart, 1877.)

As a specimen of how the Etruscan language sounded may be given the inscription from a tomb at Perugia known as the Torre di San Manno. It is the third longest of existing inscriptions. The single words are separated from each other by two dots and the lines by a vertical stroke. The last part, which is in brackets, cannot be read with certainty:—cehen : suϑi : hinϑiu : ϑues′ : sians′ : etve : ϑaure : lautnes′cle : caresri : aules′ : larϑial : precuϑuras′i : | larϑialisvle : cestnal : clenaras′i : eϑ : fanu : lautn : precus′ : ipa : murzua : cerurum : ein | heczri : tunur : clutiva : zelur [vs : cetiver : apas]. The simple vowels are *a*, *e*, *i*, *u*. Length is rarely indicated except in some doubtful cases by means of repeating the vowel. Modification of the vowels, such as occurs in various forms in the Indo-Germanic, Germanic, Semitic, and Turanian languages, is foreign to the Etruscan. It has no prefixes, and the accent appears to have been always on the first syllable, and in consequence of this arose the habit of alliding vowels in the middle of words to such an extent as to bring about frequently very disagreeable combinations of consonants. An extreme case is that of Elχsntre = Ἀλέξανδρος. Sometimes it may be due to a method of writing, though there is no evidence whatever of vowels being inherent in consonants. The diphthongs are *ai*, *au*, *ei*, *ia*, *ie*, *iu*, *ui*, and *aia*, *aie*, *eia*, *eie*, *uia*, and again *ae*, *ea*, *eu*, *ua*, *ue*, which latter appear not to be original forms. The consonants are *p*, *ϕ* (almost only in foreign words); *c* (*k*), *χ*; *t*, *θ*; *l*, *r*; *m*, *n*; *s* (*s′*), *z*; *v*, *f*, *h*. The aspiration of the tenues is very frequent, sometimes also of the mediæ in foreign words, in which cases *f* and *h* take the place of *φ*, *h* of *χ*. It is doubtful whether *f* and *h* interchange with *θ*; *h* is sometimes allided. The hard *f* is common to the Etruscan and the Italian languages, as is also its interchange with *h*. Assibilation (*e.g.*, in the name *pethnei*, which also occurs as *petsnei*, *pesnei*, *peznei*) is common. Nasal letters often fall out before mutes, and *n* when preceding a labial becomes *m* frequently, *e.g.*, *lanϕe*, *lamϕe*; *s* never changes to *r*, and the interchange of *l* and *r* is doubtful. With regard to the suffixes indicating masculine nouns, which have been wrongly used as an argument for the Italic character of the Etruscan, the most numerous series ends in *a*; the next is that in *e*; endings in *i* and *u* are comparatively rare, in *ie* and *iu* less so, while *ia* occurs only exceptionally. Consonant endings are few. There is no suffix in *p*, *ϕ*, *z*, *v*, *f*, *h*. The greater part of the feminine words, also chiefly names of persons, are derived from the masculine by the suffix *ia*; not seldom *nia*, *ta*, *θa* occur; also the diminutives *za* and *la*. Besides these, however, are a number of feminine words without corresponding masculines. As yet there is no trace of a neuter. Positive traces of declension are few. In the older inscriptions the nom. sin. in masculines ends in *s* (*s′*), which afterwards is dropped. The gen. sing. in masculine words ending in vowels, and in fem. words ending in consonants, is formed by *sa*, occasionally *ssa* = *s′a* = *za*, and shortened to *s*, *s′*, *z*. The connecting vowels *i* and *u* are used after *l* and *r*, *e.g.* *vele*, gen. sing. *velus*(*a*). But in masculines ending in consonants, and feminines ending in vowels, the gen. sing. takes *l*, originally perhaps *la*, or with connecting vowel *al*. But this system in the formation of the genitive seems to have been interrupted at an early period by the more general use of the ending *sa*. A remarkable peculiarity of the Etruscan is the apparently capricious doubling and trebling of the genitive suffix, *e.g.* *sla*. (*s′la*), and *slisa* (*slis′a*) in masculines; *lisa* [*lisa*, *lis′a*, *alisa*, (*alis′a*), *alis′*, contracted to *alsa*, *ls*, *ls′*, *als*, *als′*] and *lisala* (*lisla*, *alisala*, *alisla*, perhaps *lis-v-le*) in masculine and feminine. The dat. sing. is formed by the suffix *si* (*s′i*) attached to the nom., *e.g.*, *clan* (son), dat. *clensi* (with modification of the vowel). An accusative singular is probably to be found in the phrase *arse verse* = averte ignem, as handed down by Festus, in which case it would be similar to the nominative as in plural words. Few other cases in the singular have been traced. Possibly *æsar* is an instance of the nom. pl.; it would correspond to the conjectural acc. pl. of *clenar* from *clan* = son, from which the dat. pl. is *clenaras′i*.

As to conjugation only one form is certain, *i.e.*, the perf. 3 sing. in *ce* (*ke*), as in *turce* (*turuce*, *turke*) = dedit; *lupuce* = mortuus or mortua est; *svalce* = obiit (mortem); *amce* = fuit; *arce* = habuit; *zilaχnuce* = magistratum gessit (?). As to *lupuce*, however, and *zilaχnuce*, there is some doubt. No augment or reduplication is known. It is possible that the phrase *arse verse* contains an imperative; *mi* appears positively to mean "I am." The numerals may be given as follows:—*θu* (*θun*) = 1; *ci* = 2; *maχ* = 3; *zal* (*esal*, *esl*) = 4; *s′a* = 5; *hut* (*huth*) = 6; *semϕ* = 7; *cezp* = 8 (10–2). The tens are formed by *alch*(*a*)*l*, but irregularly, *e.g.*, *cealchl* (*celchl*) = 20; *muvalchl* (*mealchl*) = 30. In mixed numbers the units preceded the tens. Peculiar forms are *ciemzathrm*, probably = 2 and 40, and *θunesi muvalchl*, probably 1 and 30; *s* added to numerals may indicate the genitive. When *z* is added it seems to indicate repetition, *e.g.* *eslz* = 4 times. Pronouns and adverbs appear to be represented by the forms *eca*, *cehen*, *ta*, *eth*, and a few others. *An* is perhaps a preposition. The present writer believes he has discovered with certainty two enclitic conjunctions, *c* (originally perhaps *ce*) and *m* (with vowel) *um*, *em*, both equal to "and," *e.g.*, *puiac* and *puiam* = "and wife."

The following is a list of the words which have been made out from the inscriptions with tolerable certainty:—*nets′ris trutnvt* = haruspex; *fronta* (Greek?) = fulgurator; *avil* = life; *ril* = year; *tiv* = month; *tusurthir* = husband; *puia* = wife; *clan* = son; *sec* (*sech*, *s′ec*, *s′ech*) = daughter; *thura* = grandson; *lautni* = freedman; *lautnita* = freedwoman; *etera* = slave; *eteraia* = female slave; *tusna* = swan; *aefla* = dog; *krankru* = panther; *suti* (*suthi*, *s′uthi*) = tomb; *suthina* = sepulchral object; *sutna* = sarcophagus; *nesl* = grave; *naper* = niche (of tomb); *cela* (Ital.?) = sepulchral chamber; *tular* = tombstone (plural?); *cesu* = coffin; *mulvannice* (*mulenike*, etc.) = sepulchral; *hinthia* = shade, shade of the dead; *farthana* (*harthna*) = monument; *fleres* (*-res′*) = image; *tins′cvil* = dedicated object; *alpan* = work of art; *cape* (*kapi*, Italian?) = cup; *ath*(*u*)*mic* = lamps; *neviku* = earthenware vase; *nipe* = vase; *huins* = fountain; *svalce* = died; *leine* (*line*) = lived; *tur*(*u*)*ce* = gave; *amce* = was; *arce* = had; *zil achnuce* = magistratum gessit; *zilachnthas* = magistratus; *mi* = I am. To these may be added, besides the numerals and particles just cited, the following names of deities:—*Tinia* (*Tina*) = Zeus; *Uni* = Hera; *Sethlands* = Hephæstus; *Turmus* = Hermes; *Fuflunus* = Bacchus; *Turan* = Aphrodite; *Laran* (*Lalan?*) = Ares; *Lala* = Selene; *Thesan* = Eos; *Usil* (Italian?) = Helios; *Menrva* (Italian?) = Minerva; *Maris* = Dioscurus; *Lasa* = a subordinate goddess; and many other deities not yet accurately identified. From ancient writers we know also *Mantus* = Hades, *Nanos* or *Nanas* = the Etruscan Ulysses, and certain names of months:—*Vel*(*c*)*itanus* = March; *Ampiles* = May; *Aclus* = June; *Traneus* = July; *Ermius* = August; *Cælius* = September; *Xoffer* (*Utofer* in Corssen) = October. Lastly, we have the glosses:—*æsar*, *aisar* = deus; *aisoi* = θεοί; *falando* (or *falandum?*) = cœlum; *aukelos* = Ἕως; *andas* = Βορέας; *arimos* = πίθηκος; *damnos* = ἵππος; *antar* = ἀετός; *arakos* = ἱέραξ; *g*(*i*)*nis* = γέρανος; *capys* = falco; *capua* = cui pollices pedum curvi sunt; *burros* = κάνθαρος; *ataison* = ἀναδένδρας (wine); *arse verse* = averte ignem; *agaletora* = παῖδα; *lucumo* = princeps; *druna* = ἀρχή; *lanista* = carnifex; *hista* = mimus; *ludius* = saltator; *subulo* = tibicen; *nepos* = helluo; *gapos* = ὄχημα; *velites* = light-armed; *balteus* = strap of sword; *cassis* = metal helmet; *mantissa* = additamentum ponderis; *Idus* = middle of month; *atrus* = ending of word for the day after a festival. This list could be easily increased by conjectures. (W. DE.)]

Art.

Art.—It appears from a statement of Varro, quoted by Censorinus (*De Die Natali*, xvii. 5 *fol.*), that Etruscan history was divided into ten periods or *sæcula*, and it is known otherwise that the tenth of these periods began in the year 44 B.C. The first four sæcula are given as lasting each 100 years, the fifth 123, the sixth 119, the seventh 119, and allowing for the eighth and ninth each an average of 120 years, we obtain the year 1044 B.C. as the beginning of Etruscan chronology, a date which curiously corresponds with that usually assigned to those great movements of races in Greece with which the Etruscan traditions were associated. The really important point, however, in these figures, as Helbig (*Annali dell' Inst. Arch.* 1876, p. 230) has lately shown, is the circumstance that the first four periods are given in round numbers, and thus justify the inference that the keeping of regular records had not begun till the fifth period, commencing 644 B.C., a date which at the most would not be more than a century after the first introduction of the Greek alphabet into Italy by means of the Greek colonists. Apparently the oldest alphabet as yet discovered on Etruscan remains is that known as the Chalcidian-Greek. It occurs on a vase from the Regulini-Galassi tomb at Cære, and in all probability it had not reached the Etruscans before the end of the 8th century B.C. No doubt everything tends in this early period to connect the Etruscans, not with the Greeks, but with the Carthaginians and the people of Italy and Sicily opposing the then active Greek colonization, which must have seriously threatened their trade. In 537 B.C. they united with the Carthaginians, as has been mentioned, to drive out the Phocæans from Corsica. Such was the influence of Carthage in 509 B.C. that even the Romans accepted a commercial treaty with her; and among the ascertained dates of objects from Etruria may be mentioned 673-527 B.C. as that to which certain porcelain vases with hieroglyphics from Vulci and Cære are definitely assigned,—which vases again point to commerce with a people who understood and could imitate hieroglyphics. We have thus in the 7th and 6th centuries B.C. a picture of activity and frequent contact among the trading and advanced peoples of the Mediterranean which, though it implies a degree of national hostility on the part of the Etruscans towards the Greeks, need not exclude the intercourse of traders, nor a readiness to profit by the industrial and artistic skill of the Greeks. Otherwise it would be impossible to account for the legend which states that in the time of Cypselus, the tyrant of Corinth 660 B.C. (Pliny, xxxv., 12, 43), Demaratus, accompanied by certain artists, Eucheir, Diopus, and Eugrammus, settled in Etruria, and gave the first impulse to plastic art in Italy. These names sound legendary, but it may be taken that they would not have been invented unless to account for a fact which in this case is the very marked resemblance between the early art of Etruria and of Greece, a resemblance which could not have been accidental, or at any rate need not be supposed to have been so when the means of communication were so plentiful. We know, for instance, that the Etruscan silver coinage was struck on the Attic system as arranged by Solon about 590 B.C., having similar designs (*e.g.*, the face of the Gorgon), the same weight, the same nominal, with the stater as its unit and the drachme as its half, and with apparently the same sign of the half as that used at Athens for the hemiobol (Mommsen, *Römisches Münzwesen*, p. 218). Tuscan architecture, essentially Greek, approaches most closely to the early Ionic-Attic style. The general impression, however, has been that it was through Corinth rather than through Athens that Etruria came into contact with Greek art, and this not so much because of the legend just quoted as because both Corinth and Etruria enjoyed the same high reputation in antiquity for unrivalled skill of working in terra-cotta and in bronze. But doubtless there were many different sources of contact.

As regards skill in the execution of artistic designs, it would seem as if all that the Etruscans ever attained in this direction had been learned from the Greeks, and, it will be fair to suppose, from Greeks resident among them. But when we come to the subjects of these designs, it is clear that there is a difference between the early and late works in this respect, that, while in the latter the subjects as well as the style are almost always Greek, in the former there are certain obviously Oriental features. Under the circumstances it could scarcely have been otherwise, since at least from the 4th century B.C. onwards the Greeks ruled supreme in matters of art, whereas in the early period of the 7th and 6th centuries, their artistic productions, though then also doubtless by far the best attainable, had yet to compete against those of the Phœnicians or their kinsmen the Carthaginians, who in fact had been longer in the market. The characteristic of Phœnician art was its mixture and blending of the two elements of design, originally peculiar to Assyria and Egypt, upon which was afterwards engrafted, when the Greek style had developed itself, a distinctly Greek element. That Phœnician productions of the earlier class were imported into Etruria is seen for example in the silver vases from the Regulini-Galassi tomb at Cære (*Mus. Etrusco Vaticano*, i., pl. 63-66), which, always suspected to have been Phœnician, were proved to be such from their identity of style with another silver vase found at Præneste in 1875, and bearing a Phœnician inscription (*Monumenti dell' Inst. Arch. Rom.*, x., pl. 32, fig. 1). This again is artistically identical with the silver pateræ from Cyprus, descriptions of which are collected by Helbig in the *Annali dell' Inst. Arch.*, 1876, pp. 199–204. Further evidence of Phœnician importations is to be found in the porcelain vases with hieroglyphics already mentioned, in the ostrich eggs ornamented with designs from a tomb at Vulci, and now in the British Museum, and in the richly engraved shell of the species *Tridacna squamosa* peculiar to the Red Sea and Indian Ocean, also now in the British Museum. At the same time, even if this importation of works of art had been on a much greater scale than there is as yet reason to suppose it to have been, it is clear that all the artistic influence derivable in this way must have been small compared with that which would naturally have been exercised on the Etruscans by the Greek colonists of Italy, and still more by the Greek artists who had made Etruria their home, as may be inferred from the legend already quoted. (See Mommsen, *History of Rome, Eng. Transl.*, i., p. 248, who says, "The Italians may have bought from the Phœnicians; they learned only from the Greeks;" and again, p. 247, "Italian art developed itself not under Phœnician but exclusively under Hellenic influence.") Besides, the Oriental features of which mention has been made in early Etruscan art were in point of fact common in a high degree to early Greek art also, and it may have been through this channel that they found their way, rather than by direct contact with the Phœnicians or Carthaginians. In dealing with the artistic remains of the Etruscans, it will be more convenient to take them in classes, according to their material or the purpose they served, than in groups of an historical sequence. Strictly speaking there appears to be no historical development in them. There are archaic works, there are very late works, and there are works of a middle stage, but there is no growth from one to the other. The process of change consists of a leap to the next new phase of art developed by the Greeks, who, so to speak, set the fashion. It happens also that certain classes of objects went out of use or came into use with particular periods of art, and with the aid of this circumstance it will be possible to observe something approaching an historical order. We begin with the scarabs.

Scarabs.

Scarabs.—These are gems consisting usually of carnelian or banded agate, cut in the form of beetles (scarabæi), and having a flat face on which a design is engraved in intaglio. They are pierced transversely, and were attached by swivels to rings either to be worn on the finger or to be hung on a chain round the neck. The form of the scarab suggests an origin in Egypt, where, in fact, they have been found in great numbers. But excepting the form there is singularly little in common between the scarabs of Etruria and of Egypt. This is the more remarkable since the Carthaginians, from whom—or from the Phœnicians—it is naturally supposed the Etruscans had obtained the notion of this form of ornament, have left in Sardinia (at Tharros, Sulcis, and Cagliari) considerable numbers of scarabs, the designs of which are for the most part, though not purely Egyptian, yet obviously derived from that source. These Sardinian scarabs are cut in green jasper, the favorite material in Egypt, or occasionally in porcelain or glass, materials equally utilized in that country. Then also there is the fact that as yet only one or two scarabs have been found in Greece, and indeed very few engraved gems of any shape showing a fairly developed art comparable with that of the Etruscan scarabs, so that from both sides it would seem as if the Etruscans must have been dependent for models in this branch of their art on the Phœnicians or Carthaginians. On the other hand, there was a law of Solon's (Diog. Laert., i. 57) forbidding gem-engravers to keep casts or seals of rings engraved by them, and from this it is to be inferred that in his time the art was practised with the success then attending the other arts. This being admitted, the result obtained from an examination of the scarabs becomes clear. The designs, with few exceptions, are purely Greek, and as a rule they indicate the 7th and 6th centuries B.C. as the period of their origin; that is to say, the workmanship on them corresponds to the Greek workmanship of that period. So also the subjects represented. If, for instance, we take either the remains of Greek art or the existing descriptions of works executed at this time but now lost, *e.g.*, the chest of Cypselus (Pausanias, v. 17), the throne of Apollo at Amyclæ (Pausanias, iii. 18), and the paintings of Polygnotus at Delphi (Pausanias, x. 25–31), it will be seen that the chief delight of artists was then in rendering the exploits of heroes, and that figures of deities occur in comparison very rarely. Nor is this remarkable, since it was in this period that the Greeks carried the worship of their heroic but legendary ancestors to its highest point. The same result will be found in the Etruscan scarabs, if we take as fairly representative the collection in the British Museum. Out of 197 specimens, excluding those which are of too rude workmanship to be of interest in the question, 167 have subjects drawn entirely from Greek legends of heroes; of the remainder 10 represent Greek divinities, 18 such fabulous beings as centaurs, gorgons, satyrs, sirens, and harpies, all more or less connected with the heroic legends of Greece. Only two give native Etruscan deities or personifications. (See *Contemporary Review*, 1875, p. 729.) An entirely similar state of things will be found by reference to the lists of scarabs published in the "Impronte Gemmarie" (*Bullet. d. Inst. Arch. Rom*, 1831, p. 105; 1834, p. 116; 1839, p. 99). Of the Greek divinities in the Museum collection, two are represented by heads of Athene obviously copied from an early coin of Corinth, while the two heads of the Gorgon in the list stand in the same relation to a series of silver coins till recently ascribed to Athens, but now by some high authorities ascribed to Attica. Nor are these the only instances in which Greek coins have been used as models to imitate. Still, notwithstanding this, coupled also with the fact that the processes of die-sinking and gem-engraving were almost identical, it is clear in many cases that the Etruscans had not confined themselves to models from this class of objects, but had skill enough to adapt designs from other sources, and especially from statues or figures sculptured in the round as more suitable than reliefs, at least where the gem was translucent, and could be held up to the light to be looked at, as was frequently the case. A certain number of the designs are clearly treated as reliefs, but the majority exhibit a minuteness of anatomical detail and attitudes more appropriate to sculpture in the round, not necessarily, however, always to statues strictly so called, since in many cases the attitude is such that the figure could not have stood unless in one or other of the various positions assigned to figures in the pediments of temples, as for instance among the sculptures from Ægina in Munich, where the same minuteness and exactness of anatomy will be seen in the perfection to which it had attained in Greece at the close of the 6th century B.C. That the Tuscan temples were also decorated with sculptures in the pediments is known, not, however, the extent to which the designs may have been derived from the Greeks, though from the analogy of the rest of Etruscan art the probability is that they were pretty closely copied; and when Pliny (xxxv. 154), on the authority of Varro, speaks of the sculptures in all the temples of Rome previous to 493 B.C. being "Tuscan," it is fair to suppose that his *Tuscanica signa* would correspond both in style and in subject to early Greek art of the period previous to this date. That view of the case would explain why so many of the scarabs come to have subjects best suited to the decoration of temple pediments, and to indicate further at what period this particular process of studying from Greek models took place; it may be added that the oldest statue of a deity in Rome,—that of Diana in the temple on the Aventine, dedicated, according to tradition, between 577 and 534 B.C.—represented the type of the Ephesian Artemis familiar in early Greek and Etruscan art. On the scarabs, draped figures are in a great minority, the preference being, as in early Greek sculpture, for the nude, with a great display of physical structure. In a considerable number of cases the names of the personages represented are inscribed on the gems in Etruscan characters, a habit which prevailed also in early Greek art. Some few scarabs have a figure engraved in relief on the back. With comparatively rare exceptions, the intaglio is surrounded with a cable border, and when gems are found with this border but without being scarabs, it is usual to describe them as scarabs which have been cut down in more recent times for the sake of the stone, not always correctly so, since this border appears to have been occasionally adopted by Roman gem-engravers of later times. It is not impossible also that a number of the scarabs now existing, as to which generally there is little or no information concerning their *provenance*, may have been made in Rome about the time of Augustus, when a taste prevailed for the revival of archaic art. Otherwise the production of scarabs, to judge from their style, must have ceased before the beginning of the 5th century B.C. When it began is a question which depends on when Greek sculpture attained mastery in rendering the human form (probably from the 8th to the 6th centuries B.C), since it is at this stage of the art that the scarabs, so to speak, strike into it. They have none of those grotesquely conceived animals executed on steatite or other soft stones which abound on the earliest Greek gems. From the general considerations already stated, and from the likelihood that the Etruscan period of imitation would not be before the last stage of archaic art in Greece, the 6th century B.C. will be a reasonable *terminus a quo* for its start.

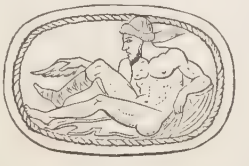

Fig. 1.—Philoctetes wounded in the foot: on a scarab in sardonyx. From *Annali*, 1857, pl. H, fig. 5.

Coins.

Coins.—Considered as works of art, the coins may be classed next to the scarabs, from the similarity of the processes by which they are made, and the limited field which they present for design. It has been already said that the silver coinage of Etruria was struck on the Attic standard as introduced by Solon in the beginning of the 6th century B.C. The gold coinage is according to the Miletus standard, which appears to have been the oldest gold standard in European Greece, including Athens, whence doubtless it was obtained by Etruria along with the silver standard (Mommsen, *Röm. Münzwesen*, p. 28). The majority of the silver and gold, as well as the light copper coins belonging to the same system, are stamped only on one side, in accordance with the early custom, the types being essentially Greek, among them the head of the gorgon (fig. 2) similar to that referred to on the scarabs, and the cuttle-fish such as appears on Greek coins, and very frequently on the early pottery from Ialysus in Rhodes, and the ornaments from Mycenæ and Spata in Attica. Whatever may be the date ultimately assigned to the antiquities just mentioned, it may be taken as certain that the Etruscan coins in question do not go back to an earlier time than that of Solon (about 590 B.C.), and may be half a century later, or even much more in some instances. Others with different types are distinctly late.

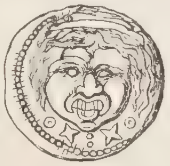

Fig. 2.—Coin of Populonia. Brit. Mus.

Black ware.

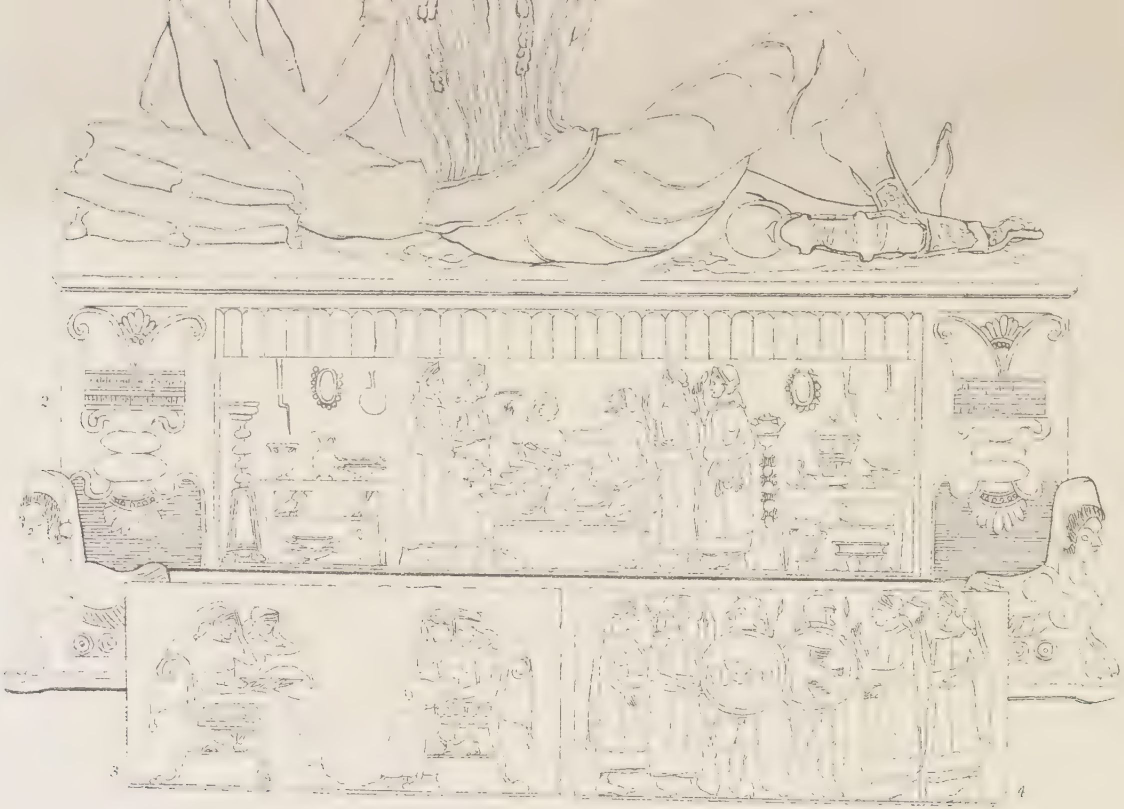
Black Ware.—Connected in a measure with the engraved gems is a series of black terracotta vases, many of which are ornamented with bands of figures in low relief pressed out in the clay when it is soft by means of an engraved cylinder rolled round the vase in such a way that the same design is constantly being repeated each time the cylinder completes a revolution. Frequently the designs are purely Oriental, either Egyptian or Assyrian, as if made directly from imported cylinders. In other cases they consist of rows of animals, the lion, deer, sphinx, and panther, followed by a winged human figure moving at speed, and perhaps representing such a being as the gorgon, altogether presenting precisely the same appearance as those early painted vases found in Greek localities, and attributed to a period of prevailing Oriental influence very justly supposed to have been communicated to the Greeks by the Phœnicians, since on Phœnician silver vases, as that of Curium (Cesnola, *Cyprus*, p. 329), very similar bands of animals occur. The nearer we approach to the main centres of Phœnician industry, as for instance at Camirus in Rhodes, the more frequent are these designs of animals. Among the cases where the design is essentially of Hellenic origin may be mentioned a large circular dish in the British Museum, having the representation of a banquet scene with two couches, and attendants dancing and playing on the flute, constantly repeated in two rows round the lip. Subjects of this kind (see Plate VIII.) abound in early Etruscan art, and, so that there may be no doubt as to whence they were derived, on the early Greek vases found in Etruria. The date of this Greek pottery would then determine that of the Etruscan, and by means of the inscriptions not seldom occurring on the former, we arrive at a period not much if at all before 600 B.C., a result which again brings us to what has already appeared to have been the first great period of contact between the Etruscans and Greeks. It is to be observed also that the earlier system of vase decoration in Greece, by means of geometric patterns, is not found in Etruscan ware. Further, on the black vases in question are to be seen often figures modelled in the round which could not have been derived from Greece before 600 B.C., since it was not till then that sculpture in the round was fairly introduced there, and could not well have been derived from Assyria, since that country appears to have never developed this branch of art, while as regards Egypt it may be answered that the figures are in no way of an Egyptian type. This black ware seems to have been chiefly a local fabric of Clusium. Still at one time it may have been general in Etruria and also in Latium, which as at Albano has yielded from under the lava a series of very ancient vases of this same texture, but without the characteristic ornamentation, which, as has been said, limits the Etruscan pottery to a period not earlier than 600 B.C., and possibly in some cases to at least a century later than this.

Jewelry.

Jewelry.—Their tombs have preserved ample evidence of the passion of the Etruscans for rich dresses and personal ornaments, the former surviving in the wall-paintings, the latter in actual specimens of goldsmith's work, consisting of necklaces, ear-rings, wreaths, bracelets, finger-rings, and fibulæ for fastening the dress. From a comparison of any large collection of these ornaments, such as that of the British Museum or of the Vatican Museum, with the same class of objects from Greece, it will be observed as a rule that where a pattern of any kind has to be produced, the Greek accomplished it skilfully and rapidly by means of fine gold wire soldered down into the required design,—that is, by filigree, as it is called; while the Etruscan preferred to give it by sometimes innumerable and almost imperceptibly minute globules of gold, each separately made, and all soldered down in the necessary order—that is to say, by granulated work. But these characteristics, essentially correct as they are, do not hold in all cases, since, on the one hand, there are numbers of Etruscan specimens where the granulated work is not employed, though it would be difficult to point to any one where the true filigree system takes its place, and since, on the other hand, granulated work is found on the early Greek ornaments from Camirus in Rhodes, now in the British Museum (for a specimen of these ornaments, see the article ARCHÆOLOGY, vol. ii. p. 306). The latter circumstance, exceptional though it is at present, may still serve to show how it may have been through the Greeks that this process of working in gold reached Etruria, in which case it must have happened at a period scarcely later than 600 B.C., the Camirus figures corresponding very markedly with the descriptions of certain figures on the chest of Cypselus. No doubt this process of working may equally well have been obtained through the Phœnicians, if we may judge by the specimens from their settlements in Sardinia, and to some degree in Cyprus, and on the whole it is likely that in this matter of personal ornament the Etruscans were more in sympathy with the Phœnicians and Orientals than with the Greeks. The bracelets, armlets, necklaces, and finger-rings worn by men on the Assyrian sculptures were precisely such as appealed to Etruscan tastes, and were not well to be had through the medium of the Greeks, unless perhaps the Greeks of Cyprus, who worked side by side with the Phœnicians. The three gold necklaces engraved by Cesnola (*Cyprus*, pl. 22–24) might have been obtained from Etruscan tombs, instead of from a treasure chamber in Cyprus, so far as the workmanship is concerned. In any case the original invention of so toilsome a process of that of the granulated work, while it cannot fairly be ascribed to the Greeks, may well have been due to the Phœnicians, whose greatest fame in very early times was for their skill in metal work, and whose products of this nature—for example, the silver pateræ of the Regulini-Galassi tomb at Cære—have been traced to Etruria as well as to Latium (Præneste) and the coast of Italy (Salerno). From the fact that with the loss of their national independence there came rather an increase than otherwise of private wealth among the Etruscans, and a consequent continuation of the demand for jewelry, it happens that there is among their remains material for the study of this branch of their art or industry in its latest as well as its earliest stages. In the earliest specimens there is a preference for figures of animals in rows, as on the early vases, followed by winged figures of deities, the artistic element of form being always very rude and mechanical. In later times the human form is introduced faithfully, true to the Greek type, and representing personages from Greek legend or mythology. Gold was the favorite material, and with it were employed amber, glass, precious stones, occasionally enamel, and seldom silver. The precious stones most in use, either for finger-rings or for necklaces, were the carnelian and agate, cut either as scarabs or as beads. Glass was made into beads. Amber served a variety of purposes, as beads, ornaments of fibulæ, where it is employed with gold, and amulets, of which one specimen in the British Museum is in the form of an ape of a species peculiar to India (*Macacus rhesus*), whence the knowledge of it has been supposed to have been conveyed by the ships of Tarshish which brought apes and peacocks from that quarter. The amber itself was obtained first of all from about the mouth of the Po, and afterwards from the Baltic as now; but whether, as has been lately maintained (Helbig, *Real Accademia dei Lincei*, Rome, 1876–7), the artistic remains in this material can be all grouped into one of two classes, representing a very early and a very late period with no intermediary stage, is a question on which perhaps more remains to be said before it is finally settled.

Bronzes.

Bronzes.—Among the articles still pertaining to personal use is the series of bronze mirrors the extent of which may be conceived from the fact that a considerable number have been found since the publication of Gerhard's work (*Etruskische Spiegel*, 1843–1867), with 430 plates, many of which give from four to six examples. These mirrors are polished on one side, and on the other have a design engraved on the bronze, taken in the majority of cases from Greek legend or mythology, and no less from an artistic point of view founded on Greek models (see fig. 3). But while this is obvious enough, it is remarkable that as yet probably not more than six engraved mirrors have been discovered in Greece itself, and except in one case even these cannot be said to bear any analogy of design to the Etruscan mirrors. Perhaps it deserves to be considered that these few specimens come from Corinth, whence, as tradition said, Greek art was introduced into Etruria. But it is not enough to suppose the first impulse towards work of this kind to have come from Greece. It is necessary to find, if not mirrors, some other classes of objects which could have supplied the Etruscans with the multitude of entirely Greek designs which they have reproduced. No doubt the painted vases were largely drawn up, especially the shallow pateræ, with designs on a circular space in the centre, as may be seen, for example, in the three mirrors in Gerhard (pl. 159, 160), where the group of Peleus carrying off Thetis, familiar on vases, is reproduced with the difference that the attributes of Heracles (bow and club) are given to Peleus. In the mirrors just mentioned the figures are rendered in low, flat relief, but this is very exceptional. In other cases also the groups appear to be taken from the centres of pediment sculptures on temples, the figures, diminishing in scale towards each side, being made to fit into the narrowing circle of the mirror. Artistically they may be arranged in three classes. The first is an archaic style, in which the subjects, drapery, and general treatment of the figures have much of a local Etruscan character, though still on the model of early Greek work; the second a free style, where everything seems Greek of about the 4th century B.C., except the names of the persons inscribed in Etruscan. Mirrors of this style have been found in Latium at Præneste, along with bronze cistæ similarly decorated with engraved designs; occasionally both on the cistæ and the mirrors are inscriptions in early Latin. The finest example of these utensils is that known as the Ficoroni cista, which, but for its bearing the name of a Latin artist, might be regarded as an excellent example of Greek art in the 4th century B.C., at which period it appears to have been largely spread in Latium as well as Etruria (Müller, *Denkmäler*, No. 309, and Brönsted, *Den Ficoroniske Cista*, Copenhagen, 1847). The third is a late and barbarous native style. The range of subjects is wide. Still it will be noticed that the almost exclusive use of mirrors by women has rendered subjects otherwise familiar, such as scenes of war, inappropriate. The labors of Heracles were much admired, as were incidents in the story of Helen, yet neither of them occur



Terracotta Sarcophagus from Cære (Cervetri). In the British Museum.

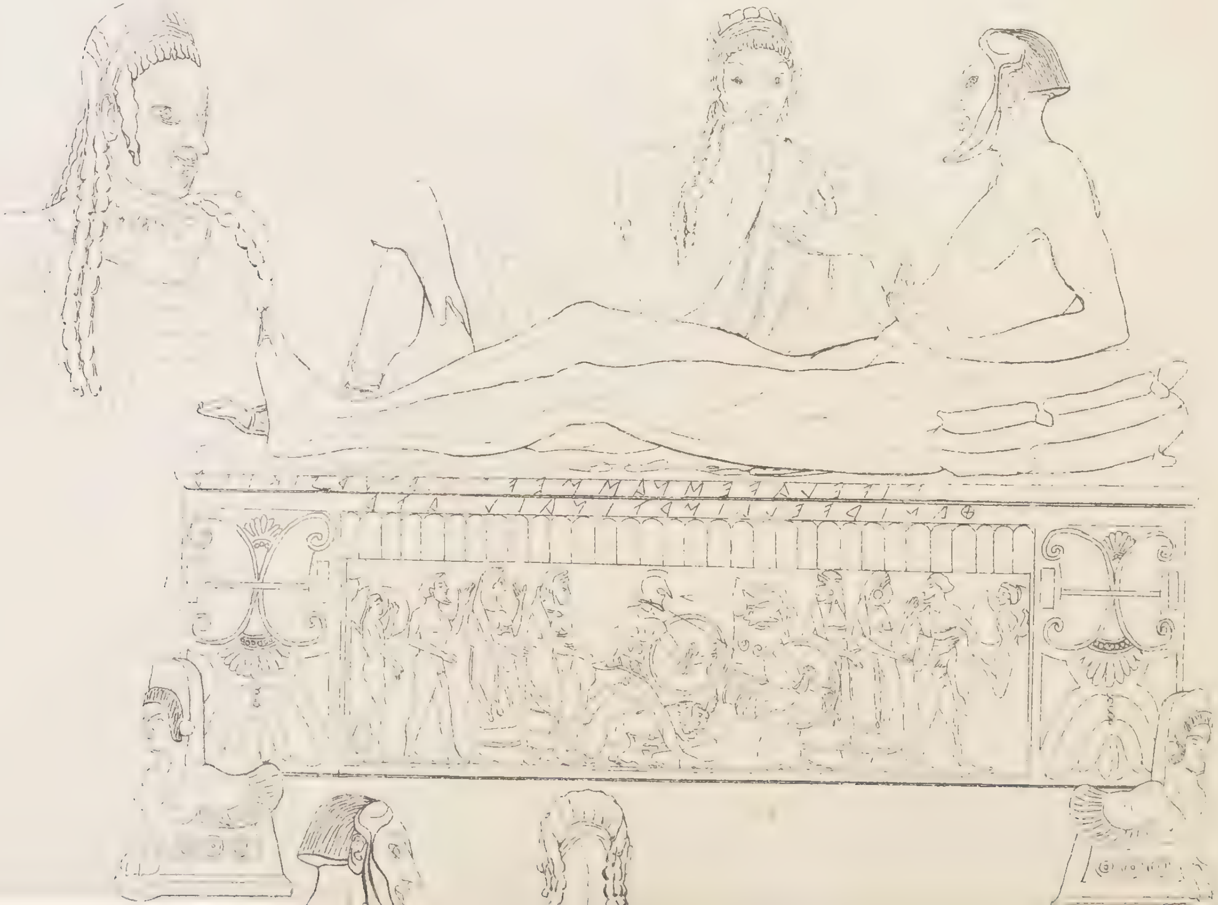
ENCYCLOPÆDIA BRITANNICA NINTH EDITION

ETRURIA



so frequently as scenes between satyrs and mænads, or the common representation of ladies at their toilet. In great numbers, but always on small or poor examples, appear certain figures which have been identified as the Cabiri, and in any case seem to have been household genii. A small number of circular mirror-cases have been found, ornamented with reliefs, of which both the subjects and the execution are in the majority of instances purely Greek, of a comparatively late period.

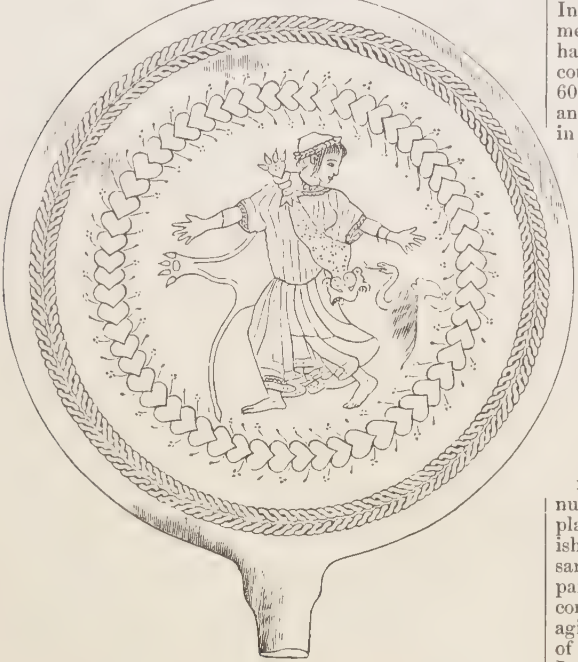


Fig. 3.—Bronze Mirror: Mænad. From Gerhard, pl. 96.

Of skill in bronze casting there is little evidence among the Etruscan remains. In one specimen in the British Museum from Sessa on the Volturno (see Costume, vol. vi. p. 403, fig. 6), a core of iron has been employed, which by expanding has burst the figure down the side; and again in another specimen in the national collection a female bust from the Polledrara tomb (Grotto of Isis) at Vulci, it will be seen that the art of casting was unknown when it was executed. It is made of a number of thin pieces of bronze plate beaten out into the form of parts of the bust, and all fastened together, sometimes with fine nails, but apparently also in places with some sort of solder. On the other hand, to judge from the vases found in this tomb, which are made of pieces riveted together with nails, it would seem as if solder could hardly have been known. The same process of uniting parts together occurs in the very ancient silver relief from Perugia (Millingen, *Uned. Mon.*, pt. ii. pl. 14). The bust from Vulci, and the vases and other antiquities discovered with it, are engraved in Micali (*Mon. Ined.*, pl. vi.–viii.). It will be seen from the porcelain vases and scarabs among them bearing hieroglyphics, and from the ostrich eggs with designs resembling those of the early Corinthian vases, that the origin of the contents of this tomb properly belongs, not only to a period of intercourse with Egypt, but to a period when that intercourse was conducted by the Phœnicians, who alone knew how to adapt designs from the Greeks on the one hand, as well as from the Egyptians on the other. Indeed, one of the scarabs bears the cartouche of Psammetichus, whose date is 666 B. C.; and though it might have been made considerably after this time, it obviously could not have come into existence before. On the whole, 600 B.C., may be set down as probably the date of these antiquities. As regards the mass of existing statuettes cast in the round, they bear generally except in the matter of dress, distinct evidence of Greek origin, not only in the style and execution, but also in the subjects (see fig. 4). Still it is noticeable, especially among the later specimens, that a very marked spirit of realism is blended with the original idealism of the Greek prototypes. This realism of the Etruscans comes out very strikingly in the portrait sculpture of their sarcophagi, and probably was a phase of artistic capacity which they shared with the Romans. The purpose of these bronze statuettes was to surmount vases and candelabra, or to serve as handles of mirrors.

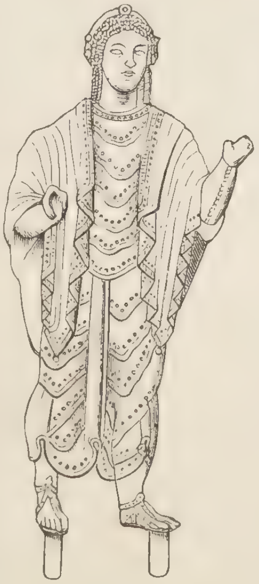

Fig. 4.—Bronze statuette. Brit. Mus. From Micali, pl. xiii. fig. 1.

Terra-cottas.
Plate VIII.

Terra-cottas.—The skilful modelling of terra-cotta, for which the Etruscans were celebrated, was, it appears, chiefly directed to the production of ornamental tiles, sarcophagi, and statues, rather than those small and mostly graceful statuettes which are found in large numbers in Greek localities. The statues which were placed on the pediments of temples have naturally perished. Specimens of the tiles and a large number of sarcophagi, however, remain, the latter being for the most part of a late period, and executed under the influence of a completely developed Greek art. Fortunately two sarcophagi of the greatest interest for the study of the early art of Etruria have been found at Cære. The one, now in the Louvre (engraved, *Mon. d. Inst. Arch. Rom.*, vi. pl. 59; cf. *Annali*, 1861, p. 402), has a male and female figure of about life size reclining on the lid. The other (for engraving of which see Plate VIII.) is now in the British Museum, and while having a similar group of figures of about life size on the lid, is besides richly decorated with bas-reliefs round the four sides. In both sarcophagi colors are freely employed, which originally must have been slightly staring, and increase the effect of realism, which in the figures on the lids is all the more conspicuous by comparison with the reliefs, where the true early Greek spirit, as seen on the vases, is strictly maintained. The reason of this difference may partly lie in the fact that Greek models for the reliefs were easily enough obtained, while on the other hand Greek figures approaching in resemblance those on the lid here must at least have been very scarce. At the same time it is also to be remembered that owing to the impossibility of counting on the places where the terra-cotta might shrink, or to what extent this might go, no other treatment would be suitable except that of a bold, rough realism, the effect of which could not easily be destroyed. With the reliefs there was no such danger. The type of face shown in these figures is not to be taken as that of the early Etruscans, for this reason that their essential peculiarities, the sloping forehead, and eyes and the corners of the mouth turned upwards, are obviously mannered exaggerations of the early Greek style of rendering these features, for which undoubtedly there may have been some small grounds in the actual features of the people. Besides on the reliefs there is very little of this exaggeration. The attitude of the figures on the lid is that of a man and wife at a banquet scene, probably here intended to indicate the eternal banquet which appears to have been considered the lot of the happy in the next world. The sarcophagus, to judge from the inscription painted on it, was that of a lady named Thania Velai Matinai Unata. Another inscription painted along the lid reads *Mi vela vesnas me vepe tursi kipa*, which, according to the interpretation of Corssen (i. p. 784), is the dedication of the monument. From the character of the letters it has been thought that this sarcophagus need not be earlier than the end of the 6th century B.C., a period which would not be unsuitable to the workmanship, if we allow that it may have retained many traditions from an earlier time, which in Greece generally had by then been abandoned. The relief on the front represents a combat of two armed men, of whom the one has received a mortal blow and is falling. From the wound his soul has escaped, and is seen in the shape of a winged figure bounding away on the extreme right. The soul of the victorious warrior comes tripping in on the extreme left. This manner of representing the soul recalls in some degree the sepulchral vases of the Athenians, where it appears as a small winged figure, and recalls also the *psychostasia* of very early times, in which the souls of two combatants were supposed to be placed in a balance and weighed against each other while the fight was proceeding. It will be seen also that the wounded warrior is already being devoured by the dog of the battle-field, thus giving an instance of what is called *prolepsis*, and is not unfamiliar in early art. That is to say, the artist has attempted to realize two separate moments of the action,—first, the actual wounding, and secondly the consequence of it, viz.,—that the body of the vanquished is left to be devoured by dogs and kites, a fate which the heroes of the *Iliad* often promise their opponents in battle.[1] That the combatants here are Achilles and Memnon is not improbable, and in this case the principal female figures will be respectively their mothers Thetis and Eos, each with an attendant; the male attendant on each side perhaps was attached to the warriors themselves. The story begins on one of the ends of the sarcophagus with the two warriors parting for battle; in the front is the combat; on the other end the mourning, and on the back the eternal banquet. The feet are formed by four sirens in their capacity as daughters of the earth sent by Persephone to assist mourners to wail for the dead (Euripides, *Helena*, 167). In other cases the sirens were thought of as carrying away the souls of the dead, as on the Harpy monument from Xanthus in Lycia. The later urns and sarcophagi will be found collected in Brunn's *Rilievi delle Urne Etrusche*, Rome, 1870.

Vases.

Vase Painting.—It has been proved that the great mass of painted vases found in Etruria, and familiarly called Etruscan, are productions of Greek workmen. The subjects, the style, and the inscriptions are all Greek. But side by side with them are certain undoubtedly Etruscan vases, the very small number of which would suggest that in this direction at least the Greek models defied imitation if indeed the attempts in question did not clearly show this. At the same time it must be admitted that between the early Corinthian vases of about the 7th century B.C., discovered in Etruria, and the probably contemporary specimens of native work there is no very great difference. It was the later development which the Etruscans could not follow. Specimens of early imitation found at Cære will be seen engraved in the *Monumenti d. Inst. Arch. Rom.*, vi. pls. 14, 15, 33, 36; vi.–vii., pl. 73, the peculiarities of which, such as in costume, type of face, disproportion between figures of men and of animals, are pointed out in detail by Helbig, *Annali d. Inst. Arch. Rom.*, xxxv., p. 210, fol. The style of the originals, including the correct degree of subordination in the design to the vase which it adorns, is lost, and in its place stands out a certain gross reality in conflict with the form of the vase. It does not follow that these imitations were made contemporary with the originals (about the end of the 7th century B.C.), but a strong argument in favor of such a view might be found in a vase from the Polledrara tomb at Vulci, the antiquities of which have been shown to belong to this period. The vase in question like the others has a design purely Greek in its subject and general treatment—Theseus struggling with the Minotaur, while Ariadne holds the clue, a chorus, chariots, and centaurs with human forelegs. But it differs in this respect, that the outlines of the figures are drawn with a crude red color upon the varnished surface of the vase, not as in other cases on spaces left unvarnished. From that circumstance, and from the general effect of these Cæretan vases as compared with the reliefs on the large sarcophagus, just described, from the same locality, it will be seen that the skilled workman of Etruria turned more readily to modelling in terra-cotta than to the complicated and difficult process of vase-painting. As regards the few attempts made in late times it may be said that they also fail in the direction of grossness. See, for example, the vase in the British Museum with Ajax falling on his sword and Actæon defending himself from his hounds. Mention, however, should be made of one specimen in the Museum collection where all the technical skill of a Greek potter is displayed, and its Etruscan origin revealed only by the subject and by certain details familiar in the mirrors. The composition of the scenes is in some respects like that of a picture with perspective, which, while it is not a feature of Greek vases, can neither be called Etruscan on the ground of any known analogy.

Mural painting.

Mural Painting.—The mural paintings of the Etruscans are known only from their tombs, the inner walls of which it was not unusual to decorate in this manner, the work being executed on a prepared ground of white stucco, and with a considerable variety of colors, red, brown, yellow, carnation, blue, green, and black, to indicate flesh, hair, dress, armor, and other adjuncts. The principal localities in which these paintings have been discovered are Veii, Chiusi, Vulci, Cære, and Tarquinii. The most important of them will be found engraved in the *Monumenti d. Inst. Arch. Rom.*, those of Tarquinii in vol. i., pls. 32–3; vi., pl. 79; viii., pl. 36, and ix., pls. 13–15*e*; from Cære, vi., pl. 30; from Vulci vi., pls. 31–2; from Chiusi, v., pls. 16, 17, 33, 34; from Veii, Micali, *Mon. Ined.*, pl. 58, figs. 1–3. For the state of opinion concerning the antiquity of this art in Etruria, see Helbig in the *Annali d. Inst. Arch. Rom.*, 1863, p. 336, and again *Annali*, 1870, p. 5–74, in reply to Brunn who had criticised his theory in the mean time in the *Annali*, 1866, p. 442. Both wrote from personal inspection, and from an acquaintance with Etruscan remains such as no other writers possess. If they differ as to whether this or that painting is older than another, they yet appear to be agreed on the main points that, taken altogether, these paintings represent three successive stages of the art, the oldest stage being characterized as Tuscan, and as exhibiting little of Greek influence, the second as strongly marked by the features of Greek painting in the phase in which it was left by Polygnotus, and the third as completely under the domination of Greek art as it existed in the Hellenistic age. It is not meant that this oldest or Tuscan school was an original creation, but only that with perhaps no better models than Greek vases, the Etruscans then developed a system of mural painting which may be called their own, the more so since its spirit of localizing its subjects by giving the figures native dress and types of face is seen at times surviving in the later stage. The tomb at Veii is assigned by Helbig to the first period, and in any case it must be ranked as early, since that town was destroyed in 396 B.C. Obviously very early are also the pictures from Cære (*Monumenti*, vi., pl. 30), where a female is being brought to an altar to be sacrificed. In the scene is an ancient statue (xoanon), a curious figure of a soul in the air, two warriors and two figures sitting face to face. It is, however, in the paintings of the second period, especially those of Tarquinii (see fig. 5), that the Etruscans show to the best advantage, as having the delicacy and refinement of drawing combined with nobility of figure ascribed by tradition to Polygnotus, and still traceable on the earlier examples of the Greek vases with red figures, wearing thin

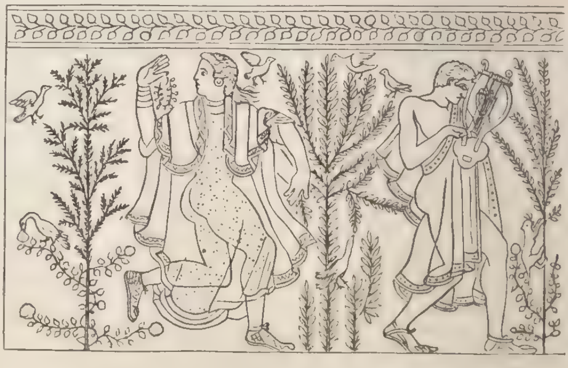

Fig. 5.—Scene from Mural Painting at Tarquinii. From the *Monumenti d. Inst. Arch.*, i., pl. 32.

---

[1] A similar instance of *prolepsis* is when Perseus is figured cutting off the head of Medusa, and already holds at his side Pegasus, the winged horse, which did not spring from her until her head was entirely off.

transparent draperies which do not conceal the forms and movements of the limbs. Here the Etruscan artist has a complete command of skill, and is obviously conscious of it from the precision with which he carries out his finest lines. The types of his figures are of pure Greek beauty, and their movement such as that on the best vases. No doubt these particular paintings are exceptional among those that remain now, but in what relation they had stood to the general run at the time when they were executed is another question. The others sin more or less in the direction already pointed out as characteristic of the Etruscans, a certain gross realism under which there probably lay artistic strength of some kind. As regards the latest stage it has little to distinguish it from Greek work except the occasional presence of peculiarly Etruscan dæmons, Etruscan inscriptions explaining the subjects, and again frequently the native realism carried sometimes to the extent of being nearly grotesque. In the early specimens the subjects consist mostly of banquet scenes attended by dances to music apparently in groves, perhaps those of Elysium, and games such as accompanied funeral obsequies in Greece, and probably also in Etruria. Doubtless these representations in the interiors of tombs were intended to realize the future life of the deceased. (A. S. M.)

ETTLINGEN, the chief town of a district in the circle of Carlsruhe, Baden, Germany, is situated at the entrance of the valley of the Alb, on the railway from Manheim to Basel, 4½ miles south of Carlsruhe. Agriculture, the rearing of cattle, and the cultivation of madder and various kinds of fruits employ a portion of the population; but they are chiefly engaged in manufactures, paper-making, cotton-spinning, weaving, cloth-dressing, and starch-making. Ettlingen possesses an old castle built on the site of a Roman fortress. This castle was burnt by the French in 1689, but was rebuilt at the beginning of the 18th century. The first notice of Ettlingen dates from the beginning of the 12th century. It was a free town till 1234, when it was presented by the emperor Frederick II. to the margrave of Baden. In 1644 it was conquered by the Weimar troops under Taupadel, and near the town Moreau was defeated by the archduke Charles 9th and 10th July, 1796. In and around Ettlingen a large number of Roman antiquities have been found. The population in 1875 was 5286.

ETTMULLER, Ernst Moriz Ludwig (1802–1877), an able and erudite philogist, who has contributed largely to the critical literature of the Germanic tongues. He was born at Gersdorf near Löbau, in Saxony, October 5, 1802, was privately educated by his father, the Protestant pastor of the village, entered the gymnasium at Zittau in 1816, and studied from 1823 to 1826 at the university of Leipsic. After a period of about two years, during which he was partly abroad and partly at Gersdorf, he proceeded to Jena, where in 1830 he delivered, under the auspices of the university, a course of lectures on the old Norse poets. Three years later he was called to occupy the mastership of German language and literature at the Zurich gymnasium; and in 1863 he left the gymnasium for the university, with which he had been partially connected twenty years before. His death took place at Zurich, 1877. To the study of English Ettmüller contributed by an alliterative translation of Beowulf, Zurich, 1840, an Anglo-Saxon chrestomathy entitled *Engla and Seaxna scopas and boceras*, Quedlinburg, 1850, and a well-known *Lexicon Anglo-Saxonicum*, Qued., 1851, in which the explanations and comments are given in Latin, but the words unfortunately are arranged according to their etymological affinity, and the letters according to phonetic relations. He edited a large number of High and Low German texts:—*Kunech Laurin*, Jena, 1829; *Wartburgkrieg*, Jena, 1830; *Sant Oswaldes Leben*, Zur. 1835; *Ortnides mervart unde tôt*, Zur. 1838; *Hadloubes Lieder unde Sprüche*, Zur. 1840; *Heinrich's von Meissen des Frauenlobes Leiche, Sprüche, Streitgedichte und Lieder*, Qued. 1843; *Frowen Helchen Süne*, Zur. 1846; *Heinrich's von Veldecke Eneide*, Leipsic, 1852; *Theophilus*, Qued. 1849; *Dat Spil van der upstandinge*, Qued. 1850; *Wizlawes IV. Lieder und Sprüche*, Qued. 1852; and to the study of the Scandinavian literatures he contributed an edition of the *Völuspa*, Leipsic, 1831, a translation of the *Lieder der Edda von den Nibelungen*, Zur. 1837, and an old Norse reading book and vocabulary. He is also the author of a *Handbuch der Deutschen Literaturgeschichte*, 1847, which includes the treatment of the Anglo-Saxon, the Old Scandinavian, and the Low German branches; and he popularized a great deal of literary information in his *Herbstabende und Winternächte: Gespräche über Dichtungen und Dichter*, 3 vols., Stuttgart, 1865–1867. The alliterative versification which he admired in the old German poems he himself employed in his *Deutsche Stammkönige*, Zur. 1844, and *Das verhängnissvolle Zahnweh, oder Karl der Grosse und der Heiliger Goar* Zur. 1852.

ETTMÜLLER, Michael (1644–1683), a German physician, born at Leipsic, May 26, 1644. After having studied languages, mathematics, and philosophy at his native town, he went to Wittenberg, and, returning to Leipsic, obtained a medical diploma there in 1666. He travelled in Italy, France, and England, and then retired to Leyden, where he had intended to spend some time in study; but he was suddenly recalled to Leipsic in 1668, and received the degree of doctor immediately after his arrival. He was admitted a member of the faculty of medicine in 1676. About the same time the university of Leipsic confided to him the chair of botany, and appointed him extraordinary professor of surgery, the duties of which he discharged with distinction. He died on the 9th March, 1683. Although Ettmüller only wrote short dissertations and mere *opuscula*, he enjoyed an immense reputation. He had the art of interesting and fixing the attention by a ready elocution, and by arguments sometimes much more specious than solid.

The following is a list of his works:—*De Singularibus*, a thesis defended by Ettmüller in 1663; *Medicina Hippocratis Chimica*, Leipsic, 1670; *Vis Opii diaphoretica*, Leipsic, 1679; *Chimia Rationalis ac Experimentalis curiosa*, Leyden, 1684; *Medicus Theoria et Praxi generali instructus*, Frankfort and Leipsic, 1685. Various editions of his collected works have been published, but the best is that of his son, who was also a physician of some eminence, entitled *Opera Medica theoretica-practica per filium Michælem Ernestum, etc.*, Frankfort, 1708, 3 vols. fol. There is no complete translation of the works of Ettmüller, but there are numerous German, English, and French translations of the different treatises.

ETTY, William, R.A. (1787–1849), one of the most eminent of British painters, was born at York, 10th March, 1787. His father had been in early life a miller, but had finally established himself in the city of York as a baker of spice-bread. He showed from his earliest years a talent for drawing, and used to make sketches whenever he could find opportunity. After some scanty instruction of the most elementary kind, the future painter, at the age of eleven and a half, left the paternal roof, and was bound apprentice in the printing-office of the *Hull Packet*. Amid many trials and discouragements he completed his term of seven years' servitude, and having in that period come by practice, at first surreptitious, though afterwards allowed by his master "in lawful hours," to know his own powers, he removed at the close of it to London. The kindness of an elder brother and a wealthy uncle, William Etty, himself an artist, stood him in good stead during his long and noble struggle against the trials and difficulties that beset the career of nearly every person who adopts the profession of art for its own sake. He commenced his training by copying without instruction from nature, models, prints, etc.,—his first academy, as he himself says, being a plaster-cast shop in Cock Lane, Smithfield. Here he made a copy from an ancient cast of Cupid and Psyche, which was shown to Opie, and led to his being enrolled in 1807 as student of the Academy, whose schools were at that time conducted in Somerset House. Among his fellow-scholars at this period of his career were some who in after years rose to eminence in their art, such as Wilkie, Haydon, Collins, Constable. His uncle generously paid the necessary fee of one hundred guineas, and in the summer of 1807 he was admitted to be a private pupil of Sir Thomas Lawrence, who was now at the very acme of his fame. Etty himself always looked on this privilege as one of incalculable value, and till his latest day regarded Lawrence as one of the chief ornaments of British art. For some years after he quitted Sir Thomas's studio, even as late as 1816, the influence of his preceptor was traceable in the mannerism of his works; but his later pictures prove that he had completely outlived it. Though he had by this time made great progress in his art, his career was still one of almost continual failure, hardly cheered by even a passing ray of success. In 1811, after repeated rejections, he had the satisfaction of seeing his Telemachus rescuing Antiope on the walls of the Academy's exhibition-room. It was badly hung, however, and attracted little notice. For the next five years he persevered with quiet and constant energy in overcoming the disadvantages of his early training with yearly growing success, and he was even beginning to establish something like a name when in 1816 he resolved to improve his knowledge of art by a journey to Italy. After an absence of three months, however, he was compelled to return home without having penetrated farther south than Florence. Struggles and vexations still continued to harass him, but he bore up against them with a patient endurance and force of will which ultimately enabled him to rise superior to them all. In 1820 his Coral-finders, exhibited at the Royal Academy, attracted much attention, and its success was more than equalled by that of Cleopatra's arrival in Cilicia, shown in the following year. In 1822 he again set out on a tour to Italy, taking Paris on his way, and astonishing his fellow-students at the Louvre by the rapidity and fidelity with which he copied from the old masters in that gallery. On arriving at Rome he immediately resumed his studies of the old masters, and elicited many expressions of wonder from his Italian fellow-artists for the same qualities which had gained the admiration of the French. Though Etty was duly impressed by the grand *chefs d'œuvres* of Raphael and Michelangelo at Rome, he was not sorry to exchange that city for Venice, which he always regarded as the true home of art in Italy. His own style as that of the most distinguished English colorist of any period held much more of the Venetian than of any other Italian school, and he admired his prototypes with a zeal and exclusiveness that sometimes bordered on extravagance. Early in 1824 he returned home to find that honors long unjustly withheld were awaiting him. In that year he was made an associate of the Royal Academy, and in 1828 he was promoted to the full dignity of an Academician. In the interval between these dates he had produced the Combat (Woman interceding for the Vanquished), and the first of the series of three pictures on the subject of Judith, both of which ultimately came into the possession of the Scottish Academy, which body, to their credit be it told, were the first to discern and publicly appreciate the genius of Etty, and the value of his contributions to art. Etty's career was from this time one of slow but uninterrupted success. His works were not now as formerly allowed to remain upon his hands unsold; and though the prices which they fetched were almost incredibly small in comparison with the value now attached to them, yet they satisfied the artist's requirements, and even tempted him to persevere in the dangerous career of high art. In 1830 Etty again crossed the Channel with the view to another art tour through the Continent; but he was overtaken in Paris by the insurrection of the Three Days, and was so much shocked by the sights he was compelled to witness in that time that he returned home with all convenient speed. During the next ten years of his life the zeal and unabated assiduity of his studies were not at all diminished, and he continued with marvellous regularity his various routine duties in connection with the academy, though his health was far from robust, and his circumstances were now such as to put it in his power to dispense with the multifarious drudgery which the fulfilment of these duties demanded. He was a constant attendant at the Life School, where he used to work regularly along with the students, notwithstanding the remonstrances of some of his fellow-Academicians, who thought the practice undignified. The course of his studies was only interrupted by occasional visits to his native city, and to Scotland, where he was welcomed, with the utmost enthusiasm, and *fêted* with the most gratifying heartiness by his brother-artists at Edinburgh. On the occasion of one of these visits he gave the finishing touches to the trio of Judiths, which form not the least interesting or valuable feature in the collection of the Scottish Academy. In 1840, and again in 1841, Etty undertook a pilgrimage to the Low Countries, to seek and examine for himself the masterpieces of Rubens which exist in many of the churches and public galleries there. Two years later he once more visited France with a view to collecting materials for what he called "his last epic," his famous picture of Joan of Arc. This subject, which would have tasked to the full even his great powers in the prime and vigor of manhood, proved almost too serious an undertaking for him in his old age. It exhibits, at least, amid great excellences, undeniable proofs of decay on the part of the painter; yet it brought a higher price than any of his earlier and more perfect works, viz., £2500. In 1848, after completing this work, he retired to York, having realized a comfortable independence. Even his advanced years and increasing infirmities were as yet unable wholly to quench his artistic enthusiasm, for when his health allowed, he worked as assiduously as in his younger days. One wish alone remained for him now to gratify; he desired to see a "gathering" of his pictures. With much difficulty and exertion he was enabled to assemble the great majority of them from various parts of the British islands; and so numerous were they that the walls of the large hall he engaged in London for their exhibition were nearly covered. This took place in the summer of 1849; on the 13th November of that same year Etty died. He received the honors of a public funeral in his native city, where he was highly respected.

Etty holds a secure place among English artists, though it is neither the place assigned to him during the early part of his career nor that to which he attained during the last thirty years of his life. Unjust neglect was followed in his case, as in that of some others, by undue and indiscriminate eulogy. His unflinching perseverance in the face of unusual difficulties and discouragements is beyond all praise. His drawing was frequently incorrect, but in feeling and skill as a colorist he has scarcely been equalled by any other English artist. His most conspicuous defects as a painter were the result of insufficient general culture and narrowness of sympathy.

See Etty's autobiography, published in the *Art Journal* for 1849, and the *Life of William Etty, R.A.*, by Gilchrist, 2 vols. 1855.

EU, a town of France in the department of Seine-Inférieure, arrondissement of Dieppe, is situated on the railway from Longpré to Tréport, and on the river Bresle 2 miles from its mouth at Tréport, and is 17 miles E.N.E. of Dieppe. It has manufactories of lace, waxcloth and sailcloth, hemp, linen, and oil, and a considerable trade in fish, corn, and wood. It is the seat of a tribunal of commerce and of a communal college, and has three ancient buildings of importance:—the beautiful Gothic church built in the 12th century, whose crypt contains the monuments of the counts of Eu; the college church, in which are the tombs of Henry of Guise and of his wife Katherine of Cleves; and the Château d'Eu.

The countship of Eu dates from the 11th century, and is descended from a side branch of the Norman kings. After the dying out of this branch it came finally into the possession of the St. Pols. In 1475 the town and castle were destroyed by Louis XI. to prevent them falling into the hands of the English; but when through marriage the countship passed into the possession of Henry, duke of Guise, he rebuilt the castle in 1581. When the house of Guise was extinguished in 1675, Eu was purchased by the princess of Montpensier, and came thus into the possession of the duke of Maine, whence it passed into that of the duke of Penthièvre, grandfather by the mother's side of Louis Philippe. In 1795 the château was converted into a military hospital, but Louis Philippe commenced its restoration in 1821, and made it his principal summer residence. Here he received Queen Victoria in 1843. It contained a large picture gallery of historical portraits, but in 1852 these were removed to England. From 1852 till the last French revolution the château belonged to Napoleon III. The population of Eu in 1872 was 3835.

EUBŒA (pronounced *Evvia* in the modern language), the largest island after Crete in the Ægean Sea, is separated from the coasts of Attica, Bœotia, Locris, and Thessaly by the Euboic Sea, which, at its narrowest part between Chalcis and the Bœotian shore, is called the Euripus. The length of the island, whose general outline is long and narrow, is about 90 miles; its breadth varies considerably,—at the broadest part it measures about 30 miles, at the narrowest not more than four. Its general direction is from N.W. to S.E., and it is traversed throughout its entire length by a mountain range, which forms part of the chain that bounds Thessaly on the E. under the names of Ossa and Pelion, and is further continued beyond the extremity of Eubœa in the lofty islands of Andros, Tenos, and Myconos. The principal peaks of this range, some of which attain a great elevation, group themselves into three knots, in the north, the centre, and the south of the island, which they thus divide with some completeness into three portions. Towards the north, opposite the Locrian territory, the highest peaks are Mounts Macistus (Kandili) and Telethrius, the former 3967 and the latter 3186 feet above the sea. Mount Telethrius was famed in ancient times for its medicinal plants, and at its foot are the celebrated hot springs, near the town of Ædepsus, called the Baths of Hercules, which were used, we are told, by the dictator Sulla, and have now been converted into an extensive bathing establishment, though the arrangements are of a rude description. These sources, which are strongly sulphurous, rise a short distance inland at several points, and at last pour themselves steaming over the rocks, which they have yellowed with their deposit, into the Euboic Sea. Opposite the entrance of the Maliac Gulf is the promontory of Cenæum, the highest point behind which, rising to an elevation of 2221 feet, is now called Lithada, the name being a corruption of Lichades, as the islands were called that lie off the extremity of the headland. Here again we meet with the legends of Hercules, for this cape, together with the neighboring coast of Trachis, was the scene of the events connected with the death of that hero, as described by Sophocles in his *Trachiniæ*. Near the N.E. extremity of the island, and almost facing the entrance of the Gulf of Pagasæ, is the promontory of Artemisium, celebrated for the great naval victory gained by the Greeks over the Persians, 480 B.C. Towards the centre, to the N.E. of Chalcis, rises the highest of its mountains, Dirphys or Dirphe, now Mount Delphi, 5725 feet above the sea, the bare summit of which is not entirely free from snow till the end of May, while its sides are clothed with pines and firs, and lower down with chestnuts and planes. It is one of the most conspicuous summits of eastern Greece, and from its flanks the promontory of Chersonesus projects into the Ægean. At the southern extremity the highest mountain is Oche, now called St. Elias, rising to the height of 4606 feet. The south-western promontory was named Geræstus, the south-eastern Caphareus; the latter of these was ill-famed on account of its dangers to navigation, for, being an exposed point, it attracts the storms, which rush between it and the neighboring cliffs of Andros as through a funnel. The whole of the eastern coast was rocky and destitute of harbors, especially the part called Cœla, or "the Hollows," where part of the Persian fleet was wrecked, which probably lay between the headlands of Chersonesus and Caphareus. So greatly was this dreaded by sailors, that the principal line of traffic from the north of the Ægean to Athens used to pass by Chalcis and the Euboic Sea.

Eubœa was believed to have originally formed part of the mainland, and to have been separated from it by an earthquake. This is the less improbable because it lies in the neighborhood of a line of earthquake movement, and both from Thucydides and Strabo we hear of the northern part of the island being shaken at different periods, and the latter writer speaks of a fountain at Chalcis being dried up by a similar cause, and a mud volcano formed in the neighboring plain. Evidences of volcanic action are also traceable in the legends connected with Hercules at Ædepsus and Cenæum, which here, as at Lemnos and elsewhere in Greece, have that origin. Its northern extremity is separated from the Thessalian coast by a strait, which at one point is not more than a mile and a half in width. From the promontory of Cenæum southwards for about fifteen miles the depth of the channel is so great that half a mile from the shore no bottom has been found with 220 fathoms of line; the water, however, gradually shoals from this point to Chalcis. In the neighborhood of that town, both to the north and south, the bays are so confined as readily to explain the story of Agamemnon's fleet having been detained there by contrary winds. At Chalcis itself the strait, assuming the name of Euripus, contracts to a breadth of not more than 120 feet, and is divided in the middle by a rock, on which now stands a castle. The channel towards Bœotia is spanned by a stone bridge, that towards Chalcis by one of wood; the latter is by far the deeper channel. The extraordinary changes of tide which take place in this passage have been a subject of wonder from classical times to the present day, and are not yet explained. As you stand on the bridge you will see the current running like a river in one direction, and shortly afterwards it will be running with equal velocity in the other. Strabo speaks of them as varying seven times in the day, but it is more accurate to say, with Livy, that they are irregular. They are referred to in several passages of the Attic tragedians. A bridge was first constructed here in the twenty-first year of the Peloponnesian war, when Eubœa revolted from Athens; and thus the Bœotians, whose work it was, contrived to make that country "an island to every one but themselves." Hence Ephorus remarked that nature might almost be said to have made that island part of Bœotia. The Bœotians by this means secured a powerful weapon of offence against Athens, being able to impede their supplies of gold and corn from Thrace, of timber from Macedonia, and of horses from Thessaly, for, as has been already said, their traffic from the north used to pass by this way. The name Euripus was corrupted during the Middle Ages into Evripo and Egripo, and in this latter form transferred to the whole island, whence the Venetians, when they occupied the district, altered it to Negroponte, with reference to the bridge which connected it with the mainland.

The rivers of Eubœa are few in number and scanty in volume, as is natural in a rocky island, where they have so short a distance to run. In the north-eastern portion the Budorus flows into the Ægean, being formed by two streams which unite their waters in a small plain, and were perhaps the Cereus and Neleus concerning which the story was told that sheep drinking the water of the one became white, of the other black. On the north coast, near Histiæa, is the Callas; and on the western side the Lelantus, near Chalcis, flowing through the plain of the same name. This plain, which intervenes between Chalcis and Eretria, and was a fruitful source of contention to those cities, is the most considerable of the few and small spaces of level ground in the island, and was fertile in corn. Aristotle, when speaking of the aristocratic character of the horse, as requiring fertile soil for its support, and consequently being associated with wealth, instances its use among the Chalcidians and Eretrians, and in the former of those two states we find a class of nobles called Hippobotæ. This rich district was afterwards occupied by Athenian cleruchs. The next largest plain was that of Histiæa, and at the present day this and the neighborhood of the Budorus (Achmet-Aga) are the two best cultivated parts of Eubœa, owing to the exertions of foreign colonists. The mountains afford excellent pasturage for sheep and cattle, which were reared in great quantities in ancient times, and seem to have given the island its name; these pastures belong to the state. The forests are extensive and fine, and are now superintended by Government officials, called *δασοφύλακες*, in spite or with the connivance of whom the timber is being rapidly destroyed—partly from the merciless way in which it is cut by the proprietors, partly from its being burnt by the shepherds, for the sake of the beautiful grass that springs up after such conflagrations, and partly owing to the goats, whose bite kills all the young growths. In the mountains were several valuable mines of iron and copper; and from Carystus, at the south of the island, came the green and white marble, the modern Cipollino, which was in great request among the Romans of the imperial period for architectural purposes, and the quarries of which belonged to the emperor. The scenery of Eubœa is perhaps the most beautiful in Greece, owing to the varied combinations of rock, wood, and water; for from the uplands the sea is almost always in view, either the wide island-studded expanse of the Ægean, or the succession of lakes formed by the Euboic Sea, together with mountains of exquisite outline, while the valleys and maritime plains are clothed either with fruit trees or with plane trees of magnificent growth. On the other hand, no part of Greece is so destitute of interesting remains of antiquity.

Like most of the Greek islands, Eubœa was originally known under other names, such as Macris and Doliche from its shape, and Ellopia and Abantis from the tribes inhabiting it. The races by which it was occupied at an early period were different in the three districts, into which, as we have seen, it was naturally divided. In the northern portion, we find the Histiæi and Ellopes, Thessalian races, which probably had passed over from the Pagasæan Gulf. In central Eubœa were the Curetes and Abantes, who seem to have come from the neighboring continent by way of the Euripus; of these the Abantes, after being reinforced by Ionians from Attica, rose to great power, and exercised a sort of supremacy over the whole island, so that in Homer the inhabitants generally are called by that name. The southern part was occupied by the Dryopes, part of which tribe, after having been expelled from their original seats in the south of Thessaly by the Dorians, migrated to this island, and established themselves in the three cities of Carystus, Dystus, and Styra. The name of the last-mentioned place, however, gives evidence of a previous Phœnician settlement, for it is a corruption of Astarte, which is found in the form Astyra at several places on the coasts of the Ægean. The Phœnicians were attracted hither, as they were to other points on the shores of Greece, by the purple-mussel, which was obtained in the Euboic Sea. The population at the present day is made up of elements not less various, for many of the Greek inhabitants seem from their costumes to have immigrated, partly from the mainland, and partly from other islands; and besides these, the southern portion is occupied by Albanians, who probably have come from Andros; in the mountain districts nomad Wallach shepherds are found; and at Chalcis there are a certain number of Turkish and Jewish families, who live quietly with the other inhabitants, and are not molested.

The history of the island is for the most part that of its two principal cities, Chalcis and Eretria, the latter of which was situated about 15 miles S.E. of the former, and was also on the shore of the Euboic Sea. The neighborhood of the fertile Lelantian plain, and their proxmity to the place of passage to the mainland, were evidently the causes of the choice of site, as well as of their prosperity. Both cities were Ionian settlements from Attica, and their importance in early times is shown by their numerous colonies in Magna Græcia and Sicily, and such as Cumæ, Rhegium, and Naxos, and on the coast of Macedonia, the projecting portion of which, with its three peninsulas, hence obtained the name of Chalcidice. In this way they opened new trade routes to the Greeks, and extended the field of civilization. How great their commerce was is shown by the fact that the Euboic scale of weights and measures was in use at Athens and among the Ionic cities generally. They were rival cities, and at first appear to have been equally powerful; one of the earliest of the sea-fights mentioned in Greek history took place between them, and in this we are told that many of the other Greek states took part. It was in consequence of the aid which the people of Miletus lent to the Eretrians on this occasion that Eretria sent five ships to aid the Ionians in their revolt against the Persians; and owing to this, that city was the first place in Greece Proper to be attacked by Datis and Artaphernes in 490 B.C. It was utterly ruined on that occasion, and its inhabitants were transported to Persia. Though it was restored after the battle of Marathon, on a site at a little distance from its original position, it never regained its former eminence, but it was still the second city in the island. From this time its neighbor Chalcis, which, though it suffered from a lack of good water, was, as Strabo says, the natural capital from its commanding the Euripus, held an undisputed supremacy. Already, however, this city had suffered from the growing power of Athens. In the year 506, when the Chalcidians joined with the Bœotians and the Spartan king Cleomenes in a league against that state, they were totally defeated by the Athenians, who established 4000 Attic colonists on their lands, and seem to have reduced the whole island to a condition of dependence. Again, in 446, when Eubœa endeavored to throw off the yoke, it was once more reduced by Pericles, and a new body of settlers was planted at Histiæa in the north of the island, after the inhabitants of that town had been expelled. This event is referred to by Aristophanes in the *Clouds* (212), where the old farmer, on being shown Eubœa on the map "lying outstretched in all its length," remarks,—"I know; we laid it prostrate under Pericles." The Athenians fully recognized its importance to them, both as supplying them with corn and cattle, as securing their commerce, and as guaranteeing them against piracy, for its proximity to the coast of Attica rendered it extremely dangerous to them when in other hands, so that Demosthenes, in the *De Corona*, speaks of a time when the pirates that made it their headquarters so infested the neighboring sea as to prevent all navigation. But in the 21st year of the Peloponnesian war the island succeeded in regaining its independence. After this, we find it taking sides with one or other of the leading states, until, after the battle of Chæronea, it passed into the hands of Philip, and finally into those of the Romans. By the great Demetrius Poliorcetes, Chalcis was called one of the three fetters of Greece, Demetrius on the Gulf of Pagasæ and Corinth being the other two.

In modern history Eubœa or Negroponte comes once more prominently into notice at the time of the fourth crusade. In the partition of the Eastern empire by the Latins which followed that event, the island was divided into three fiefs, the occupants of which ere long found it expedient to place themselves under the protection of the Venetian republic, which thenceforward became the sovereign power in the country. For more than two centuries and a half during which they remained in possession, it was one of the most valuable of their dependencies, and the lion of St. Mark may still be seen, both over the sea gate of Chalcis (Negroponte), and in other parts of the town. At length in 1470, after a valiant defence, this well-fortified city was wrested from them by Mohammed II., and the whole island fell into the hands of the Turks. One desperate attempt to regain it was made by Morosini in 1688, when the city was besieged by land and sea for three months; but owing to the strength of the place, and the disease which thinned their ranks, the assailants were forced to withdraw. At the conclusion of the Greek War of Independence, in 1830, the island was delivered from the Turkish sway, and constituted a part of the newly established Greek state. The present population of Chalcis is about 5000 souls. (H. F. T.)

EUBULIDES, a native of Miletus, was a philosopher of the Megaric school. The principal events in his personal history are quite unknown. Indirect evidence shows that he was a contemporary, whether older or younger is not certain, of Aristotle, whose philosophy he attacked with great bitterness, and that he numbered Demosthenes for a while among his pupils. He is not known to have written any independent work, and his name has been preserved chiefly on account of some celebrated, though false and captious, syllogisms of which he was the reputed author. There is reason to believe that some of these were due to others of the Megaric school.

EUCALYPTUS, a genus of trees of the natural order *Myrtaceæ*, mostly, if not all, indigenous to Australia and Tasmania. In Australia the Eucalypti are commonly called "gum trees," or "stringy-bark trees," from their gummy or resinous products, or fibrous bark. The genus, from the evidence of leaf remains, appears to have been represented by several species in Eocene times (see Schimper, *Traité de Paléontographie Végétale*, 1874). The leaves are leathery in texture, hang obliquely or vertically, and are studded with glands which contain a fragrant volatile oil. The flowers are apetalous, and resemble those of the myrtle, and the bud is closed by a lid, which is discarded when the flower expands. Within the hardened calyx, which constitutes the fruit, very numerous minute seeds are contained. The Eucalypti are rapid in growth, and many species are of great height, *E. amygdalina* attaining to even as much as 480 feet, or 150 feet more than the highest specimen of the *Wellingtonia* (*Sequoia*) *gigantea*, with a diameter of 81 feet (see *Journ. of Forestry*, March, 1878). The Blue Gum tree, *E. globulus*, Labill., is so called from the rounded form of its operculated calyx. The leaves of trees from three to five years of age are large, sessile, and of a glaucous-white color, and grow horizontally; those of older trees are ensiform, 6–12 inches long, and bluish-green in hue, and are directed downwards. The flowers are single or in clusters, and nearly sessile. This species is one of the largest trees in the world, and may attain a height of 375 feet. Since 1854 it has been successfully introduced into the South of Europe, Algeria, Egypt, Tahiti, New Caledonia, Natal, and India, and has been extensively planted in California, and, with the object of lessening liability to droughts, along the line of the Central Pacific Railway. It would probably thrive in any situation having a mean annual temperature not below 60° F., but it will not endure a temperature of less than 27° F. At Cannes the tree was raised from seed in March, 1862, and in 1872 had reached a height of 60 feet (see *Trans. Bot. Soc. Edinb.*, xii. 153). Its property of destroying the miasma of marshy districts is probably attributable to the drainage effected by its roots, rather than to the antiseptic exhalations of its leaves. To the same cause, also, is ascribed the gradual disappearance of mosquitoes in the neighborhood of plantations of this tree, as at Lake Fezzara, in Algeria. Since about 1870, when the tree was planted in its cloisters, the monastery at St. Paolo a la trè Fontana has become habitable throughout the year, although situated in one of the most fever-stricken districts of the Roman Campagna (see R. D. Glover, *Pharm. Journ. and Trans.*, Feb. 5, 1876). An essential oil is obtained by aqueous distillation of the leaves of this and other species of Eucalyptus, which, according to Faust and Homeyer (*Ber. deutsch. Chem. Ges.*, 1874, 1429), consists of cymol, an oxidized compound allied to cymol, and two terpenes. The oil has a camphoraceous odor, and is employed in perfumery and for the making of varnishes. Except as regards its action on light, the oil of *E. oleosa* is similar in smell and other properties to cajeput oil. *E. globulus*, *E. resinifera*, and other species yield what is known as Botany Bay kino, an astringent dark-reddish amorphous resin, which may be obtained in a semi-fluid state by making incisions in the trunks of the trees. The kino of *E. gigantea* contains a notable proportion of gum. From the leaves and young bark of *E. mannifera* and *E. viminalis* is procured Australian manna, a hard, opaque, sweet substance, containing melitose. On destructive distillation the leaves yield much gas, 10,000 cubic feet being obtained from one ton. The wood is extensively used in Australia as fuel, and the timber is of remarkable size, strength, and durability. The bark of different species of Eucalyptus has been used in paper-making and tanning, and in medicine as a febrifuge. The tincture of Eucalyptus, for the preparation of which the narrow leaves are reputed to be the best, has a warm, aromatic, and bitter taste, somewhat like that of cubebs. It excites the flow of saliva when in the mouth, and is a powerful diaphoretic. Its administration augments the alvine evacuations, lowers arterial tension, and increases the action of the heart, and has been found efficacious in hysteria, asthma, chorea, cerebral anæmia, and more especially in bronchorrhœa and chronic catarrh of the bladder. According to Bartholow, it is far inferior to quinine in intermittent fever. Eucalyptus leaves are smoked for the relief of asthma, bronchitis, and whooping-cough, and have been employed instead of lint for dressing wounds. From the blossoms of the Red Gum tree, *E. rostrata*, the natives of West Australia prepare a favorite beverage by steeping them in water.

For further details see Bentley, *On the Characters, Properties, and Uses of Eucalyptus Globulus and other species of Eucalyptus*, 1874; *The Year Book of Pharmacy*, 1874, pp. 29–31, and E. Cosson, "Note sur l'acclimatation de l'Eucalyptus Globulus," in *Bullet. de la Soc. de Géogr.*, vi. sér., t. 9, p. 641, where numerous references to works on the subject will be found; R. Bartholow, *Practical Treatise on Materia Medica*, 1877; Planchon, "L'Eucalyptus Globulus au point de vue botanique, etc.," in *Rev. des Deux Mondes*, Jan., 1875. For a figure, see Bentley and Trimen, *Medical Plants*, tab. 109.

EUCHARIST, the sacramental ordinance instituted by Christ and enjoined on His church as of perpetual obligation, in which bread broken and wine poured out, after solemn benediction by the appointed minister, are partaken of by the faithful in commemoration of His atoning sufferings and death, and the benefits thereby purchased for mankind, and as a means by which those benefits are conveyed to the worthy recipient. This ordinance has been constantly observed without essential variation, by all sections of the Christian church, from the time of its appointment to the present day. The only exception is that of the Quakers (or "Society of Friends"), who, from an exalted idea of the spiritual nature of Christianity, have discarded the Eucharist, together with all other religious symbolical acts. All other Christians have at all times agreed in regarding the Eucharist as their highest act of worship, and the most solemn ordinance of religion.

To understand the Eucharist aright we must go back to the history of its institution. This is given by the first three evangelists in their gospels, and by St. Paul in his first epistle to the Corinthians (Mat. xxvi. 26, 27; Mark xiv. 22–24; Luke xxii. 19, 20; 1 Cor. xi. 23–25). These narratives inform us that the Eucharist was ordained by Christ at the close of the paschal supper which He had eaten with His disciples the night preceding the day of His crucifixion; that

> "As they were eating, Jesus took bread, and having given thanks, blessed and brake it, and gave it to His disciples, and said 'Take, eat; this is My Body which is being given for you. Do this for a memorial of Me.' In the same manner also He took the cup after they had supped, and having given thanks, gave it to them, saying, 'Drink ye all of this: for this is My Blood of the new covenant'—or 'the new covenant in My Blood'—'which is being shed for you and for many, for the remission of sins. Do this as often as you drink, for a memorial of Me.'"

The first subject for remark is the connection of the Eucharist with the Paschal celebration. In the Paschal Supper the flesh of a lamb was solemnly eaten in remembrance of the preservation of the Israelites, by means of the blood of a lamb, from the destruction brought upon the Egyptians, and of the consequent emancipation of the nation from slavery to Pharaoh. In the Eucharist the same act, that of eating, assumes a similar commemorative force. The broken bread, declared by Christ to be a symbol of His crucified Body, taken and eaten, together with the drinking of the wine, declared to be a symbol of His shed Blood, becomes, in virtue of His institution, a memorial of His sacrifice as the Lamb of God who, by His death, has taken away the sin of the world, delivering man from the wrath of God, and setting him free from the slavery of evil. In this, however, the Eucharist transcends the passover which was its type, that the one was a bare commemoration, the other unites with it an actual participation in the spiritual blessings thus commemorated. However much various sections of the church have differed as to the mode and the degree in which these blessings are conveyed, and the exact relation borne by the bread and wine to the Body and Blood of our Lord, there has been a substantial agreement as to the fact that the fruits of the sacrifice of Christ are in the Eucharist in a special manner imparted to the souls of worthy recipients.

So much we may learn as to the nature of the rite from the occasion of its first institution. An examination of the mode of its institution by Christ will show what ceremonial actions may be regarded as essential to the truth of its symbolical character. These are—(1) the benediction and consecration, *i.e.*, the setting apart from profane uses, by solemn prayer and thanksgiving, of bread and wine; (2) the fraction or breaking of the bread and the pouring out of the wine into the cup; (3) the delivery and distribution of the "elements"—as the bread and wine are termed—to the communicants; (4) the declaration accompanying this distribution, that these elements both symbolize the sacrifice of Christ's death, and also convey to the faithful partaker the benefits of that sacrifice; and (5) the actual partaking of these elements by the acts of eating and drinking. These several actions are all included in Christ's command, "Do this in remembrance of Me."

The various names by which this holy rite has been designated, each expressing one view of its manifold nature, will help us towards a comprehension of its meaning and purpose.

1. The term *Eucharist*, though not found in this sense in Holy Scripture, came into use in the earliest times, and found such acceptance that it became the most frequent designation of the Lord's Supper both in the Western and the Eastern Church. It first appears in the letters ascribed to Ignatius, 107 A.D. (*Epist. ad Philad.*, c. iv.; *ad Smyrn.*, c. vi.), and is used by Irenæus, who says that after consecration "it is no longer common bread, but eucharist" (lib. iv. c. 18, § 5). Justin Martyr, 140 A.D., after describing the sacred meal, says, "This partaking is called by us the Eucharist" (*Apolog.*, i. c. 66). Origen also speaks of "the bread called Eucharist" (*Contr. Cels.*, lib. viii. § 57). The term is also continually found in this sense in Tertullian, Clemens Alexandrinus, and Cyprian. Eucharist, εὐχαριστία, signifies "thanksgiving," and its use for the sacramental feast is derived from the thanksgiving of our Lord at the institution of the rite (εὐχαριστήσας ἔκλασεν). The elements over which thanks had been offered readily assumed the name of the act of thanksgiving, and so the word *eucharistia* came to be simply equivalent to the sacramental bread and wine, and was sometimes restricted to the bread alone. "In the earliest liturgies thanksgiving was, next to the reception, the chief part of the celebration, a circumstance which without doubt served greatly to promote the general adoption of the name" (Scudamore, *Notitia Eucharistica*, p. 8). It is thus St. Chrysostom explains the term: "The awful mysteries, laden with mighty salvation, which are celebrated at every communion, . . . are called Eucharist, because they are the commemoration of many benefits, and by all means they work upon us to be thankful" (*Homil.* xxv. *in Matt.*, § 3).

2. Another familiar name is the *Communion*, or the *Holy Communion*. This is derived from the words of St. Paul, 1 Cor. x. 16, 17. "The cup of blessing which we bless, is it not the communion (κοινωνία) of the blood of Christ? The bread which we break, is it not the communion of the body of Christ? For we, the many, are one bread and one body; for we all partake of that one bread." The general use of this term is not so early as of the word "eucharist," but it is found in Irenæus, 167 A.D., who speaks of slaves who have heard from their masters that "the divine communion is the body and blood of Christ" (*Fragm.*, xiii.), and it is used by Hilary, Basil, and Chrysostom. St. Paul's

words show that the leading idea contained in this name is, that by means of this sacrament all faithful recipients become partakers of the body and blood of Christ, and receive a communication of the blessings of His sacrifice. But they also express another fundamental truth, expressed in the Apostles' Creed as "the communion of saints," viz., the communion or fellowship which all Christians have with one another, as members of one body, sharers in one life, of which the joint participation of this sacrament is an outward symbol and pledge. "By this sacrament is signified and sealed that union which is among our Saviour's true disciples communicating therein; their being together united in consent of mind and unity of faith, in mutual good will and affection, in hope and tendency to the same blessed end, in spiritual brotherhood and society; especially on account of this communion with Christ, which most closely ties them one to another; they, partaking of this one individual food, become translated, as it were, into one body and substance" (Barrow, *Doctrine of the Sacraments*, vol. v. p. 602, ed. 1818). To establish this union is declared by Christ to be one great purpose of His incarnation and death and high-priestly intercession (John xvii. 22, 23). And the Eucharist by its symbolism sets forth the truth that the only way of thus uniting men to each other is by first uniting them to Christ. They must be one *with* Him before they can be one with each other *in* Him. "The union of mankind, but a union begun and subsisting only in Christ, is what the Lord's Supper sacramentally expresses" (*Ecce Homo*, p. 175). Participation in the Eucharist being thus the chief outward sign and pledge of communion and fellowship with the church, admission to this sacrament was practically identified with a recognition of a claim to membership in the church, while to be repelled from it amounted to exclusion from the Christian body, such exclusion receiving the name of *excommunication*.

3. Another designation of this sacrament, derived from Holy Scripture, is the *Lord's Supper*. It is so called by St. Paul himself, who when speaking of its unworthy reception, says, "When ye come together into one place, this is not to eat the Lord's Supper," 1 Cor. xi. 20. The special appropriateness of this name, taking us back to the time and place of its first institution by Christ, "the same night that He was betrayed," secured for it an early and wide reception, and we find Chrysostom and Augustine employing it as a familiar term. "He gave the supper consecrated by His own hands to the disciples. We have not sat down at that feast, and yet by faith we daily eat the same supper" (August., *Serm.* cxii., c. 4). The name "supper" indicates also the original idea of the sacred rite as a common meal, "the most natural and universal way of expressing, maintaining, and, as it were, ratifying" corporate union. "The meal consists of bread and wine, the simplest and most universal elements of food; and when men of different nations or degrees sit and kneel together, and receive, as from the hand of God, this simple repast, they are reminded in the most forcible manner of their common human wants, and their common character as pensioners on the bounty of the universal Father" (*Ecce Homo*, pp. 173, 174). And thus this designation guards against a common but dangerous misconception of the sacrament. A "supper" is something to be partaken of, not to be worshipped. Bread and wine are viands to be eaten and drunk, not to be adored. That on which they are placed is a table, round which the guests gather as for a common meal, not, except in a secondary and derived sense, an altar.

4. The term "oblation" or "offering" (προσφορά) was originally applied to each of the various offerings made by the faithful at the celebration of the Eucharist, *e.g.*, the oblation of alms in kind or money for the poor, gifts for the support of the clergy, and the maintenance of the fabric of the church and its services; the special oblation of bread and wine for the purpose of the celebration; and the spiritual oblation of the Body and Blood of Christ in the eucharistic commemoration. Gradually its reference became narrowed. We notice the process of restriction in the writings of Cyprian, 250 A.D., and find it established by the time of Cyril of Jerusalem, 350 A.D. Henceforward, "the oblation" signifies the commemoration of the self-oblation of Christ on the cross. "To attain to the oblation" or to "partake of the holy oblation" meant to receive, and to impart "the oblation" was to administer the blessed sacrament." In the liturgy of the Church of England the word "oblation" is only used of the "alms" and other offerings of the congregation (with a special reference to the presentation of the elements of bread and wine), and of the actual death of Christ as "a full, perfect, and sufficient sacrifice, *oblation*, and satisfaction for the sins of the whole world," while the idea is also extended to the spiritual oblation of themselves by the faithful communicants in the words—"Here we offer and present ourselves, our souls and bodies, to be a reasonable sacrifice."

5. From "oblation" we are naturally led to the consideration of the term *Sacrifice*, which from primitive times had been applied to the Eucharist. The original reference of this term, as of the term "oblation," was to the bread and wine and other thank-offerings presented at the celebration. But its application was gradually extended so as to embrace the whole rite, and especially the central act, the presentation of the elements to God as a memorial of the sacrifice of the death of Christ. In this sense the Eucharist is spoken of from the time of Tertullian downwards, as "a commemorative sacrifice," *i.e.*, a rite, instituted by Christ himself, in which the church commemorates and pleads before the Father the one all-sufficient sacrifice made by His Son on the cross. This is no fresh immolation of the body of Christ, but a representation of that sacrifice which was once for all accomplished on Calvary, by which, according to St. Paul's words (1 Cor. xi. 26), we "do show" or "proclaim" (καταγγέλλετε) "the Lord's death till He come." The true sense in which the Eucharist may be called a sacrifice is clearly set forth in the following passage from the learned and pious Bishop Beveridge:—

> "The sacrifice that is most proper and peculiar to the gospel is the sacrament of our Lord's Supper, instituted by our Lord himself, to succeed all the bloody sacrifices of the Mosaic law. For though we cannot say, as some absurdly do, that this is such a sacrifice whereby Christ is again offered up to God both for the living and the dead, yet it may as properly be called a sacrifice as any that was ever offered, except that which was offered by Christ himself,—for His, indeed, was the only true expiatory sacrifice that ever was offered. Those under the law were only types of His, and were called sacrifices only upon that account, because they typified and represented that which He was to offer for the sins of the world. And therefore the sacrament of Christ's body and blood may as well be called by that name, as they were. They were typical, and this is a commemorative sacrifice. They foreshowed the death of Christ to come; this shows His death already passed. . . . . This is properly our Christian sacrifice, which neither Jew nor Gentile can have any share in (Heb. xiii. 10). We have an altar where we partake of the great sacrifice which the eternal Son of God offered up for the sins of the whole world, and ours among the rest."—(*Sermon* viii. vol. i. p. 50; *Libr. Angl. Cath. Theol.*)

6. Finally, we have the names, *the Sacrament of the Body and Blood of Christ, the Sacrament of the Eucharist, the Sacrament of the Altar*. This is not the place to speak of the origin and meaning of the word *sacrament* as an ecclesiastical term. Suffice it to say that the word "sacrament," when applied to the Eucharist, is used in its derived sense as an outward and visible symbol of some inward and spiritual truth, or work of grace,—in the same sense in which Augustine says of the bread and cup that they are "therefore called sacraments, because in them one thing is seen, another understood" (*Serm.* cclxxi.).

We must not altogether pass over the word *mass*, "missa," by which the Eucharist is commonly known in the Roman church. Unlike the other designations of which we have been speaking, this has no essential connection with the eucharistic rite,—"missa" originally meaning nothing more than the dismissal of a congregation. "Ite, missa est," is the formula with which the Roman eucharistic service concludes. "By degrees," writes Waterland, "it came to be used for an assembly and for church service. From signifying a church service in general, it came at length to denote the communion service in particular, and so that most emphatically came to be called the mass." (*Of the Institution of the Holy Communion*, ch. 1.) This name is not found in Holy Scripture; it was unknown to the first ages of the church; the earliest known example of its use is in Ambrose (*Epist.* 20 [33], § 4, *ad Marcellin.*) "missam facere cœpi," and it is unmeaning and inappropriate as a name of the sacrament to which it has accidentally attached itself, and it has been therefore wisely disused by the reformed church (*cf.* Scudamore, *u.s.*, p. 3).

We now proceed to speak of the mode and time of the celebration of the Eucharist. It is evident from St. Paul's words and practice (1 Cor. xi. 17–34; Acts xx. 7) that in the apostolic church the administration took place, after our Lord's pattern, in the evening, and in close connection with an ordinary meal. The disorders referred to by the apostle, which indicated the danger of this connection, before long caused a separation of the religious from the ordinary meal, and invested the Eucharist with a character of special sacredness. The time of celebration, we learn from the notices in the earlier fathers, was either after nightfall or before daybreak, these times being selected so as to avoid attracting the attention of their heathen neighbors. Pliny, in his well-known letter to Trajan, 104 A.D., speaks of the Christians in Bithynia coming together on a set day before it was light, "to sing to Christ as God, and bind themselves by a sacrament (*sacramento*) to commit no crime." Tertullian also speaks of the reception of "the sacrament of the Eucharist in assemblies even before dawn." (*De Cor. Mil.*, c. iii.) The evening celebration lingered on for a while, but it was gradually given up, and entirely ceased by the 4th century, except on some special days, such as the eves of Christmas, Easter, and Pentecost. The earliest account of the celebration of the Eucharist, that of Justin Martyr, *c.* 140 A.D., shows the extreme simplicity of the rite at that time. The day of administration was Sunday. It took place at the conclusion of the common prayer, and was preceded by the kiss of peace. The celebrant was "the president of the brethren" (*ὁ προεστώς τῶν ἀδελφῶν*). The materials of the sacrament were "bread and a cup of wine mixed with water." After prayer and praise offered by the president, to which the congregation responded "amen," the "deacons" gave to each one present, "to partake of the bread, and wine mixed with water, over which the thanksgiving had been pronounced" (*εὐχαρισθέντος*, "consecrated as a eucharist"), and carried away a portion to those who were absent from the rite. This food, he concludes, is "called by us the Eucharist" (*Apolog.*, i. c. 65–67). St. Cyril of Jerusalem furnishes us with a detailed description of the eucharistic celebration in the middle of the 4th century (*c.* 347 A.D.). By this time the ritual had become fixed, and of a somewhat elaborate character. The ceremonial commenced with the celebrant and presbyters washing their hands. This was followed by the kiss of peace, the "*Sursum Corda*," the "*Vere Dignum*," the "*Sanctus*," the "*Epiclesis*," or invocation to the Holy Spirit to sanctify the elements lying on the Holy Table, the *Prayer for all conditions of men*, and the *Commemoration of the departed.* These were succeeded —forming the point of transition to the more distinctly sacramental portion of the service—by the *Lord's Prayer*, the "*Sancta Sanctis*" (corresponding to the "fencing the table" of the Presbyterian Church), the *Unus Sanctus*, etc., and *Communion.* The minute directions Cyril gives as to the manual actions in communicating, and the application of the consecrated elements to the eyes and other organs of sense, indicate a wide departure from primitive simplicity, and a growing tendency to regard the eucharist as a religious charm (*Catech.*, xxiii.; *Mystagog.*, v.). The account of the ritual presented by St, Chrysostom (*2 Cor.*, *Homil.* xviii.) corresponds in all essential points with that given by Cyril, and we gather from the writings of St. Augustine that the canon of the North African churches differed little from it. We may conclude, therefore, that by the middle of the 4th century the eucharistic ritual was established with an essential uniformity in all parts of the Catholic Church, and in a form corresponding in its chief outlines with the canon of the extant primitive liturgies. Of these liturgies the most important, as having the best grounded claim to a primitive character (though overlaid with later additions from which it is not easy to disentangle the primitive elements), are those which bear the titles of the liturgy of St. James, St. Mark, Nestorius, the Ambrosian and Gregorian, and the Gallican liturgies.

With regard to the frequency of Holy Communion, although it has been concluded with much probability from Acts ii. 46 that the earliest Christians, in the first fervor of their faith, partook of the Eucharist daily, appearances are rather in favor of a weekly celebration on the Lord's day being the rule in the apostolic and primitive church. It was on "the first day of the week" that the Christians met for breaking bread at Troas (Acts xx. 7); and St. Paul's direction to the Corinthian Christians to lay by for the poor on that day may be reasonably associated with the oblations at the time of celebration. Pliny tells us that it was on a "fixed day," *stato die*, the Christians in Bithynia came together for prayer and communion, and, as we have seen, Justin Martyr speaks of Sunday by name (*ἡ λεγουένη ἡλίου ἡμέρα*) as the day of celebration. When Christianity became the established religion of the Roman world, the daily celebration of the Eucharist became the general rule, though the words of Augustine—"in some places no day passes without an offering; in others, offering is made on the Sabbath only, and the Lord's day; in others on the Lord's day only" (*Epist.* 118, *ad Januarium*)—prove that the rule was not universal.

The liturgy of the Church of England, by providing a collect epistle and gospel, evidently contemplates the celebration of the Eucharist every Sunday and holy day of the year. No strict rule, however, on the subject is laid down in any of her formularies. The frequency of the administration is left to the discretion of the parish priest, with this proviso, that it be frequent enough to enable every parishioner to comply with the rubric which enjoins that "he shall communicate at the least three times in the year, of which Easter to be one." In the Roman Church, the mass being the chief religious service, absorbing into itself nearly all public acts of worship, the Eucharist is celebrated daily in all churches, and in churches where there are many altars many times a day.

This article may be suitably concluded with a brief statement of the doctrinal views respecting the Eucharist of some of the chief churches of Christendom, drawn from their authoritative documents.

To commence with the Roman Church. With regard to the doctrine known as *transubstantiation*, it must here suffice to say that the Church of Rome teaches that the whole substance of the bread and wine in the Eucharist is converted by consecration into the Body and Blood of Christ, in such a manner that Christ in His entirety, including His human soul and His divine nature, is contained in the elements; and that with such a thorough transmutation that not only is the whole Christ contained in the wine as well as in the bread, but with the same completeness in each particle of the bread, and in each drop of the wine. The denial of the cup to the laity, therefore, does not deprive them of any blessing, inasmuch as whosoever receives even a crumb of the consecrated bread receives Christ in His completeness, and that not only by spiritual, but by actual and real manducation. The Church of Rome also teaches that the Eucharist is a propitiatory sacrifice offered to God the Father on every occasion when this sacrament is celebrated, and that not only for the sins of those who partake of it, but for those of all mankind, as well dead as living. (See decrees of Council of Trent, canon 1–6, 8; and *Catechismus ad Parochos*, pp. 246, 249, 250, ed. 1567, Louvain.)

The eucharistical doctrines of the Orthodox Greek Church may be best gathered from the *Ὀρθόδοξος ὁμολογία τῆς πίστεως τῆς καθολικῆς καὶ ἀποστολικῆς ἐκκλησίας τῆς ἀνατολικῆς*, subscribed by the chief patriarchs, and published in 1643. This document shows that the Greek Church is at one with that of Rome with regard to transubstantiation and the sacrifice of the mass. In *Quæstio 107* it is laid down that the intention of the celebrant is essential for the validity of the rite, and that immediately on the pronunciation of the *Epiclesis*, transubstantiation takes place, and the bread is changed into the very Body of Christ and the wine into His very Blood, the species of bread and wine alone remaining. The same article declares the benefits of the sacrament to be—(1) the commemoration of the sinless passion and death of Christ; (2) a propitiation and reconciliation before God for the sins as well of the dead as of the living; (3) the presence of Christ in the communicant furnishing a safeguard against the temptations and perils of the devil (Kimmel, *Monumenta Fidei Eccl. Orient.*, pp. 180–184). It was also definitely declared in the *Confession of Dositheus*, at the synod of Jerusalem, 1672, that unbelievers as well as believers are partakers of Christ in the Eucharist, the one receiving Him to eternal life and the other to eternal damnation; and that it is one and the same Christ, not many, that is partaken of in all the Eucharists throughout the world; and that He cannot be divided, but is present in His entirety in the smallest portion of the bread and wine (*Ibid.*, pp. 458–60).

While the Continental Reformers were of one mind in repudiating the Roman doctrine of transubstantiation and the sacrifice of the mass, very wide differences existed between them in their estimate of the grace imparted by the Eucharist, and the mode of the presence of Christ in that sacrament.

The symbolical books of the Lutheran Church, following the teaching of Luther himself, declare the doctrine of the real presence of Christ's body and blood in the Eucharist, *together with* the bread and wine (*consubstantiation*), as well as the ubiquity of His body, as the orthodox doctrine of the church. One consequence of this view was that the unbelieving recipients are held to be as really partakers of the body of Christ in, with, and under the bread as the faithful, though they receive it to their own hurt. (Hagenbach, *Hist. of Doctr.*, ii., 300.)

Of all the Reformers, the teaching of Zwingli was the furthest removed from that of Luther. At an early period he asserted that the Eucharist was nothing more than food for the soul, and had been instituted by Christ only as an act of commemoration and as a visible sign of His body and blood (*Christenliche Ynleitung*, 1523, quoted by Hagenbach, *Hist. of Doctr.*, ii. 296, Clark's translation). But that Zwingli did not reject the higher religious significance of the Eucharist, and was far from degrading the bread and wine into "nuda et inania symbola," as he was accused of doing, we see from his *Fidei Ratio at Carolum Imperatorem* (*Ib.*, p. 297).

The views of Calvin were intermediate between those of his two great contemporaries. "Though he pointed out the sacramental character, and together with it the more profound mystical significance of the Lord's Supper more distinctly than Zwingli, according to his own interpretation it is the believer only who partakes in a spiritual manner of Christ's body existing in heaven" (Hagenbach, ii. 293, § 258). While Zwingli lays principal stress upon the historical fact, and the idea of an act of commemoration, Calvin attaches greater importance to the intimate union of the believers with Christ. Thus in his opinion the Eucharist is not only a commemoration of a past event, but also the pledge and seal of something then actually present. As bread and wine sustain our earthly body, so the body and blood of Christ nourish and refresh our spiritual nature (Hagenbach, *u.s.*, p. 302). With regard to the participation of unbelievers, the Helvetic Confession lays down definitely that they who approach the Lord's Table without faith partake of the sacrament alone, but have no share in the "res sacramenti" which is the source of life and salvation (*Corpus Confession.*, p. 73).

The doctrine of the Church of England, as set forth in her 28th Article, is that "the supper of the Lord is not only a sign of the love that Christians ought to have among themselves one to another, but rather is a sacrament of our redemption by Christ's death, insomuch that, to such as rightly, worthily, and with faith receive the same, the bread which we break is a partaking of the body of Christ, and likewise the cup of blessing is a partaking of the blood of Christ. . . . The body of Christ is given, taken, and eaten in the supper only after an heavenly and spiritual manner, and the means whereby the body of Christ is received and eaten in the supper is faith." The teaching of the Catechism is to the same effect, viz., that the sacrament of the Lord's Supper was ordained "for the continual remembrance of the sacrifice of the death of Christ, and of the benefits which we receive thereby." It teaches also that "the body and blood of Christ are verily and indeed taken and received by the faithful," to "the strengthening and refreshing of our souls by the body and blood of Christ as our bodies are by the bread and wine."

The doctrine of the Presbyterian Churches of Scotland, as declared in the *Confession of Faith*, agreed upon by the Assembly of Divines at Westminster, and approved by the General Assembly in 1647, and established by Acts of Parliament in 1649 and 1690, as "the publick and avowed confession of the Church of Scotland," is that the Lord's Supper was instituted by Christ, to be observed to the end of the world "for the perpetual remembrance of the sacrifice of Himself in His death; the sealing all benefits thereof to true believers; their spiritual nourishment and growth in Him; their further engagement in and to all duties which they owe to Him; and to be a bond and pledge of their communion with Him, and with each other as members of His mystical body. In the sacrament Christ is not offered up to His Father, nor any real sacrifice made at all for remission of sins of the quick or dead, but only a commemoration of that one offering up of Himself, by Himself upon the cross, once for all, and a spiritual oblation of all possible praise unto God for the same. . . . The outward elements in this sacrament, duly set apart to the uses ordained by Christ, have such relation to Him crucified as that truly, yet sacramentally only, they are sometimes called by the name of the things they represent,—to wit, the body and blood of Christ,—although in substance and nature they still remain truly and only bread and wine. Worthy receivers outwardly partaking of the visible elements in this sacrament do then also inwardly by faith, really and indeed, yet not carnally and corporally, but spiritually, receive and feed upon Christ crucified and all benefits of His death, the body and blood of Christ being then not corporally or carnally in, with, or under the bread and wine, yet as really, though spiritually, present to the faith of believers in that ordinance as the elements themselves are to their outward senses" (chapters xxix. §§ 1, 2, 5, 7).

EUCHRE, a game at cards, much played in America. Euchre is said to be a corruption of the word écarté; the game is believed to have been first played by the French settlers in Louisiana, but at what date is uncertain. Euchre is played with thirty-two cards, the twos, threes, fours, fives, and sixes being rejected from a complete pack. The players cut for deal, and the lowest deals. The non-dealer then cuts to his opponent, who deals five cards to each, by two at a time and three at a time, or *vice versâ.* The dealer turns up the top of the undealt cards for trumps. In suits not trumps the cards rank as at whist; in the trump suit the knave (called the *right bower*) is the highest trump, and the other knave of the same color, black or red, as the case may be (called the *left bower*), is the next highest, this card being, of course, omitted from the suit to which it would otherwise belong. The other trumps rank as already stated, the queen being next above the ten.

Two-handed Euchre.—The non-dealer looks at his hand and decides whether he will play it. If content, *i.e.*, if he thinks he can win three tricks, he says "order it up." The dealer then puts out from his hand any card he pleases, face downwards, and is entitled to take the trump card into his hand; but the card is generally left on the pack until wanted in the course of play. If the non-dealer is not content, he says "pass." The dealer then has the option of taking up the trump as before, or of passing also. If the trump is *ordered up* or *taken up* the play of the hand commences; if both pass, the dealer places the trump card face upwards under the pack, called *turning it down.* The non-dealer has then the option of *making it*, *i.e.*, of naming any suit, except the one turned up, saying, "make it spades," or any suit he prefers, and that suit becomes trumps, or of passing again, saying, "pass again." If he makes it, the play begins; if he passes again, the dealer has similarly the option of making it. If both pass a second time the hand is thrown up, and the other player deals. When the turn up is red and the trump is made red it is called *making it next;* the same if black is made black. If the trump is made of a different color from the turn up, it is called *crossing the suit.* If the hand is played, the non-dealer leads; the dealer plays to the card led. He must follow suit if able, otherwise he may play any card he pleases. If the left bower is led a trump must be played to it. The highest card of the suit led wins the trick; trumps win other suits. The winner of the trick leads to the next. If the player who orders up, takes up, or makes the trump wins five tricks, he scores two, called a *march;* if he makes three or four tricks he scores one, called the *point.* If he fails to make three tricks he is *euchred*, and his opponent scores two. The game is five up. By agreement, a player who makes more than five may carry the surplus (called a *lap*) to the next game. Also it is sometimes agreed that a love game (or *lurch*) shall count double. The game may be reckoned without reference to the adverse score; or it may be played with points, that is, the winner receives from the loser as many points as he wants of game.

Three-handed or Cut-throat Euchre.—The option of playing or passing goes to each in rotation, beginning with the player to the dealer's left. Three cards, one from each hand, constitute a trick. The player who orders up, takes up, or makes the trump plays against the other two, except at *independent euchre,* when each plays for himself. If the attacking player is euchred, he is *set back* two points. Thus if he is love, and is euchred, he has seven points to make instead of five.

Four-handed Euchre is generally played with partners, who are cut for and sit opposite each other as at whist. If the first hand passes, the second may say "I assist," which means that the dealer (his partner) is to take up the trump. The hand is then played as at whist, four cards constituting a trick. The eldest hand has the next deal. If a player has a very strong hand he may *play alone* single-handed against the two adversaries. His partner cannot object. A player can declare to play alone when he or his partner orders up, or when his partner assists, or when he makes the trump, or (if dealer) when he takes up the trump, but not when the adversary orders up, assists, or makes the trump. If the lone player wins a march he scores four, if he wins three or four tricks he scores one; if he fails to win three tricks the opponents score two.

Hints.—1. The chances are that the dealer has one trump in hand; if you order up, you must expect to meet two trumps. Therefore, you should not order up unless your hand gives you a two to one chance of winning three tricks against two trumps, and your cards are such that you would have a worse chance if you made the trump. If strong in trumps and equally strong in another suit, it is always right to pass. Also, if you have the point certain, whether you make the trump or not, you should pass, in hopes the dealer may take up the trump.

2. If you pass and the dealer turns it down, you should not make the trump unless you have a two to one chance of winning three tricks against one trump.

3. If you hold good cards in two suits of different colors, and you make the trump, you should make it next. For, the dealer having turned it down in one color, is less likely to hold a bower of that color than of the other. At the four-handed game the non-dealer and his partner should also avoid crossing the suit. But if the dealer's partner makes the trump, he should not hesitate to cross the suit, as the dealer, having turned it down, has probably no bower in that suit.

4. At four-handed euchre, the eldest hand should be very strong to order it up; but the second player should assist if he has something more than one trick, *e.g.,* an ace and a trump, or two aces. If, however, he is strong in the non-trump suits, he should not assist unless he can be pretty sure of making two tricks. The third hand should be cautious of ordering up, as his partner, having passed, must be weak. This applies with still more force to taking up by the dealer, as his partner, not having assisted, must be very weak. To take up the dealer should be pretty sure of two tricks, and have a chance of a third.

5. If the dealer takes up the trump he should keep two cards of a suit, unless his single card is an ace. Thus, with queen, seven of one suit and king single of another, the king should be discarded.

6. Lead from a guarded suit unless in fear of losing a march, when lead your highest single card. Lead from a sequence of three trumps. At four-handed euchre always lead a trump with three. Also lead a trump if you have made it next; if your left-hand adversary has assisted (unless a bower is turned up); and if your partner orders up, assists, takes up, or makes the trump. Further, lead a trump if you have lost two tricks and won the third, unless your partner has dealt and still has the turn up in hand.

7. As a rule make tricks when able. Passing or finessing is seldom good play.

8. If your partner orders up, assists, takes up, or makes the trump, trump the trick whenever you can.

9. In discarding during the play, as a rule, keep a guarded card in preference to a single one, except a single ace.

10. If the adversary is at three do not order up unless you have very good cards. If the adversary is at four take up the trump on a light hand.

11. At four-handed euchre, if the dealer is one or two, and the eldest hand four, he should order up, unless he has one certain trick, in order to prevent the opponent from playing alone. This position is called *the bridge.*

12. At four-all, if the eldest hand or third hand has a trick and the chance of a second, and such cards that he would be no better off if he made the trump, he should order it up.

13. The eldest hand, and next to him the dealer, may play alone on weaker hands than the other players. The leader, with a lone hand, should lead his winning trumps; if two tricks are thus made, and the leader has a losing trump, he should then lead his best card out of trumps. When playing against a lone hand, lead an ace. If you have not one, lead your highest card out of trumps, except with a guarded king and another suit, when lead the latter. Also, keep cards of the suits your partner discards, but do not throw an ace, even if your partner keeps your ace suit.

Laws of Euchre.—*Dealing.*—1. If the dealer gives too many or too few cards to any player, or if he turns up two cards, it is a misdeal, and the next player deals. 2. If the dealer exposes a card, or if there is a faced card in the pack, there must be a fresh deal. *Playing.*—3. Any one playing with the wrong number of cards can score nothing that hand. The same if, when the trump is ordered up, the dealer omits to discard before he or his partner plays. 4. When more than two play, exposed cards can be called. Also a card led out of turn may be called, or a suit from the side offending at their next lead. 5. A player not following suit when able may correct his mistake before the trick is turned and quitted or he or his partner plays to the next trick, the card played in error being an exposed card. If the error is not corrected a revoke is established. A player revoking is euchred, and cannot score anything that hand. 6. A player making the trump must abide by the suit first named. 7. If, after the trump is turned, a player reminds his partner that they are at the point of the bridge, the latter loses the right to order up. 8. Each player has a right to see the last trick. (H. J.)

EUCLID. Of the lives of the Greek mathematicians generally very little is known, and among the number Euclid is no exception; we are ignorant not only of the dates of his birth and death, but also of his parentage, his teachers, and the residence of his early years. In some of the editions of his works, as will be seen, he is called *Megarensis,* as if he had been born at Megara in Greece, a mistake which arose from confounding him with another Euclid, a disciple of Socrates. Proclus, the Neo-Platonist (412–485 A.D.), is the authority for most of our information regarding Euclid, which is contained in his commentary on the first book of the *Elements.* He there states that Euclid lived in the time of Ptolemy I., king of Egypt, who reigned from 323 to 285 B.C., that he was younger than the associates of Plato, but older than Eratosthenes (276–196 B.C.) and Archimedes (287–212 B.C.). Euclid is said to have founded the mathematical school of Alexandria, which was at that time becoming a centre, not only of commerce, but of learning and research, and for this service to the cause of exact science he would have deserved commemoration, even if his writings had not secured him a worthier title to fame. Proclus preserves a reply made by Euclid to King Ptolemy, who asked whether he could not learn geometry more easily than by studying the *Elements*—"There is no royal road to geometry." Pappus of Alexandria, whose date is rather uncertain, but is probably a century earlier than that of Proclus, says that Euclid was a man of mild and inoffensive temperament, unpretending, and kind to all genuine students of mathematics. This being all that is known of the life and character of Euclid, it only remains therefore to speak of his works.

Among those which have come down to us the most remarkable is the *Elements* (Στοιχεῖα). They consist of thirteen books; two more are frequently added, but there is reason to believe that they are the work of a later mathematician, Hypsicles of Alexandria. At the outset of the first book occur the definitions or explanations of the meanings of the terms employed; the postulates, which limit the instruments to be used in the constructions to the ruler and the compasses; and the axioms or common notions, the fundamental principles from which mathematical truths are deduced. The propositions, which consist of both theorems and problems, deal with rectilineal figures, principally the triangle and the parallelogram, and the book concludes with the celebrated Pythagorean theorem and its converse. The second book is occupied with the consideration of the rectangular parallelograms contained by the segments of straight lines, and their relation to certain squares. It contains only two problems, the one to divide a straight line in medial section ("the divine section," as it was afterwards called), and the other which shows how to effect the quadrature of any rectilineal area. The third book, prefaced with a few definitions, discusses the properties of circles. The fourth book contains no theorems. The problems are on the inscription in, and circumscription about, circles of triangles, squares, and certain regular polygons, and on the inscription of circles in, and the circumscription of circles about, some of these figures. Though, in the definitions preliminary to this book, Euclid explains when a rectilineal figure is inscribed in and circumscribed about another rectilineal figure, he has given no proposition showing how in any case such inscription or circumscription may be effected. The equilateral triangle, the square, the regular pentagon, and such regular polygons as can be derived from these, were the only regular figures known to be inscriptible in a circle by means of elementary geometry, till Gauss discovered, in 1796, that the circumference of a circle could be divided into 17 equal parts. In his *Disquisitiones Arithmeticæ*, published in 1801, it is proved that there can be inscribed in a circle any regular polygon, the number of whose sides is prime, and is denoted by 2^n+1. Euclid's second book presupposes, that is, depends to some extent upon, the first; the third presupposes both the first and second; the fourth presupposes the first three; and all four are largely concerned with the discussion of the absolute equality or inequality of certain magnitudes. The fifth book stands alone, depending upon none of the preceding books, and contains the theory of proportion, with respect not merely to geometrical magnitudes, such as lines, angles, areas, solids, but to any magnitudes of which multiples can be formed. The diagrams consist of straight lines, probably for convenience of construction, but the enunciations of the propositions and the reasoning are perfectly general. With the exception of his treatment of parallels, Euclid's doctrine of proportion has been the subject of more discussion than any other part of the *Elements*. The foundation of the doctrine is the criterion of proportionality laid down in the famous fifth definition. The necessity or the appropriateness of such a criterion can be seen only when the distinction between number and magnitude has been clearly apprehended, or, what amounts to the same thing, when an adequate conception has been formed of incommensurables. The ordinary arithmetical test of proportionality will then be found to suit only certain cases which occur—those, namely, where the magnitudes considered are commensurable, and if the theory of proportion is to be rigorous and complete (as Euclid's is), it must be extended to incommensurables by the notions of continuity and limits. The difficulty therefore which is felt by readers of the fifth book in grasping Euclid's doctrine is due mainly to the nature of the subject, and no very material simplification of the full treatment of proportion is possible. The sixth book contains the application of the theory of proportion, mostly to rectilineal figures. In the last proposition, the second part of which is due to Theon, it is noteworthy that the restricted definition of an angle, given in the first book, and adhered to throughout, is tacitly abandoned. The seventh, eighth, and ninth books are arithmetical, that is, treat of the properties of numbers. The definitions relating to them occur at the beginning of the seventh book, and some of these show perhaps the tendency of the Greeks, natural enough to a scientific people with a defective numerical notation, to consider quantity from a geometrical point of view. A number composed of two factors was called a plane number, one composed of three a solid number, and the factors themselves were called sides. The test by which numbers are recognized to be proportionals is different from that given in the fifth book, for here it requires to be applied only to quantities which are commensurable, namely, integers. The last proposition of the ninth book shows how to construct a perfect number, that is, a number which is equal to the sum of all its divisors; for example, $6=1+2+3$, $28=1+2+4+7+14$, etc. The tenth book is the longest of the *Elements*. It is occupied with the consideration of commensurable and incommensurable magnitudes, and ends with the proposition that the diagonal and the side of a square are incommensurable. With regard to straight lines, Euclid distinguishes between those which are commensurable or incommensurable in length, and those which are so in power, the latter being defined to be straight lines the squares on which have or have not a common measure. There are three sets of definitions to this book, the second set inserted before the forty-ninth proposition, and the third before the eighty-sixth. The eleventh, twelfth, and thirteenth books treat mainly of solid geometry. In the eleventh are given the definitions which serve for the three books, the principal properties of straight lines and planes of solid angles, and of parallelepipeds. The twelfth book begins with two theorems of plane geometry, and then discusses chiefly the properties of pyramids, cones, and cylinders. The last two propositions relate to spheres, the last being to prove that spheres have to one another the triplicate ratio of their diameters. In this book is exemplified the method of Exhaustions, which is founded on the principle that by taking away from a magnitude more than its half, from the remainder more than its half, and so on, a remainder is at length reached which is less than any assignable magnitude (book x. prop. 1). Other applications of this method, the nearest approach made by the ancients to the differential calculus, are to be found in the works of Archimedes (see his *Measurement of the Circle*, *Conoids and Spheroids*, *Sphere and Cylinder*). The thirteenth book treats of lines divided in extreme and mean ratio, of some regular figures inscribed in circles, and of the five regular solids, the last proposition being to exhibit the edges of these five solids, and to compare them with one another.

The question has often been mooted, to what extent Euclid, in his *Elements*, is a discoverer or a compiler. To this question no entirely satisfactory answer can be given, for scarcely any of the writings of earlier geometers have come down to our times. We are dependent on Pappus and Proclus for the scanty notices we have of Euclid's predecessors, and of the problems which engaged their attention; for the solution of problems, and not the discovery of theorems, would seem to have been their principal object. From these authors we learn that the property of the right-angled triangle had been found out, the principles of geometrical analysis laid down, the restriction of constructions in plane geometry to the straight line and the circle agreed upon, the doctrine of proportion, as well as loci, plane and solid, and some of the properties of the conic sections investigated, the five regular solids (often called the Platonic bodies) and the relation between the volume of a cone or pyramid and that of its circumscribed cylinder or prism discovered. Elementary works had been written, and the famous problem of the duplication of the cube reduced to the determination of two mean proportionals between two given straight lines. Notwithstanding this amount of discovery, and all that it implied, Euclid must have made a great advance beyond his predecessors (we are told that "he arranged the discoveries of Eudoxus, perfected those of Theætetus, and reduced to invincible demonstration many things that had previously been more loosely proved"), for his *Elements* supplanted all similar treatises, and, as Apollonius received the title of "the great geometer," so Euclid has come down to later ages as "the elementator."

The first six and, less frequently, the eleventh and twelfth books are the only parts of the *Elements* which are now read in the schools or universities of the United Kingdom; and, within recent years, strenuous endeavors have been made by the Association for the Improvement of Geometrical Teaching to supersede even these. On the Continent, Euclid has for many years been abandoned, and his place supplied by numerous treatises, certainly not models of geometrical rigor and arrangement. The fact that for twenty centuries the *Elements*, or parts of them, have held their ground as an introduction to geometry is a proof that they are, at any rate, not unsuitable for such a purpose. They are, speaking generally, not too difficult for novices in the science; the demonstrations are rigorous, ingenious, and often elegant; the mixture of problems and theorems gives perhaps some variety, and makes their study less monotonous; and, if regard be had merely to the metrical properties of space as distinguished from the graphical, hardly any cardinal geometrical truths are omitted. With these excellences are combined a good many defects, some of them inevitable to a system based on a very few axioms and postulates. Thus the arrangement of his propositions seems arbitrary; associated theorems and problems are not grouped together; the classification, in short, is imperfect. That is the main objection to the retention of Euclid as a school-book. Other objections, not to mention minor blemishes, are the prolixity of his style, arising partly from a defective nomenclature, his treatment of parallels depending on an axiom which is not axiomatic, and his sparing use of superposition as a method of proof. A text-book of geometry which shall be free from Euclid's faults, and not contain others of a graver character, and which shall at the same time be better adapted to purposes of elementary instruction, is much to be desired, and remains yet to be written.

Of the thirty-three ancient books subservient to geometrical analysis, Pappus enumerates first the *Data* (Δεδομένα) of Euclid. He says it contained 90 propositions, the scope of which he describes; it now consists of 95. It is not easy to explain this discrepancy, unless we suppose that some of the propositions, as they existed in the time of Pappus, have since been split into two, or that what were once scholia have since been erected into propositions. The object of the *Data* is to show that when certain things—lines, angles, spaces, ratios, etc.—are given by hypothesis, certain other things are given, that is, are determinable. The book, as we are expressly told, and as we may gather from its contents, was intended for the investigation of problems; and it has been conjectured that Euclid must have extended the method of the *Data* to the investigation of theorems. What prompts this conjecture is the similarity between the analysis of a theorem and the method, common enough in the *Elements* of *reductio ad absurdum*,—the one setting out from the supposition that the theorem is true, the other from the supposition that it is false, thence in both cases deducing a chain of consequences which ends in a conclusion previously known to be true or false.

The *Introduction to Harmony* (Εἰσαγωγὴ Ἁρμονική), and the *Section of the Scale* (Κατατομὴ Κανόνος), treat of music. There is good reason for believing that one at any rate, and probably both, of these books are not by Euclid. No mention is made of them by any writer previous to Ptolemy (140 A.D.), or by Ptolemy himself, and in no ancient codex are they ascribed to Euclid.

The *Phænomena* (Φαινόμενα) contains an exposition of the appearances produced by the motion attributed to the celestial sphere. Pappus, in the few remarks prefatory to his sixth book, complains of the faults, both of omission and commission, of writers on astronomy, and cites as an example of the former the second theorem of Euclid's *Phænomena*, whence, and from the interpolation of other proofs, Gregory infers that this treatise is corrupt.

The *Optics* and *Catoptrics* (Ὀπτικά, Κατοπτρικά) are ascribed to Euclid by Proclus, and by Marinus in his preface to the *Data*, but no mention is made of them by Pappus. This latter circumstance, taken in connection with the fact that two of the propositions in the sixth book of the *Mathematical Collection* prove the same things as three in the *Optics*, is one of the reasons given by Gregory for deeming that work spurious. Several other reasons will be found in Gregory's preface to his edition of Euclid's works.

In some editions of Euclid's works there is given a book on the *Divisions of Superficies*, which consists of a few propositions, showing how a straight line may be drawn to divide in a given ratio triangles, quadrilaterals, and pentagons. This was supposed by John Dee of London, who transcribed or translated it, and entrusted it for publication to his friend Federic Commandine of Urbino, to be the treatise of Euclid referred to by Proclus as *τὸ περὶ διαιρέσεων βιβλίον*. Dee mentions that, in the copy from which he wrote, the book was ascribed to Machomet of Bagdad, and adduces two or three reasons for thinking it to be Euclid's. This opinion, however, he does not seem to have held very strongly, nor does it appear that it was adopted by Commandine. The book does not exist in Greek.

The fragment, in Latin, *De Levi et Ponderoso*, which is of no value, and was printed at the end of Gregory's edition only in order that nothing might be left out, is mentioned neither by Pappus nor Proclus, and occurs first in Zamberti's edition of 1537. There is no reason for supposing it to be genuine.

The following works attributed to Euclid are not now extant:—

1. Three books on *Porisms* (Περὶ τῶν Πορισμάτων) are mentioned both by Pappus and Proclus, and the former gives an abstract of them, with the lemmas assumed. A porism, according to Pappus, was neither a theorem nor a problem, but something of an intermediate form, which yet could be enunciated as a theorem or as a problem. Later geometers, he says, defined it to be a local theorem wanting part of the hypothesis, but this definition he censures as imperfect. After the publication of Commandine's translation of Pappus (1588), many attempts were made to extract from this unsatisfactory description a clear idea of what a porism was, and, with the help of the lemmas, to restore Euclid's books. The mystery, which baffled the penetration even of Edmund Halley, was not resolved till the time of Simson, who, in 1722, gained some insight into the subject, and whose posthumous treatise *De Porismatibus* appeared in 1776. Simson's views have been objected to by recent French writers, such as M. Paul Breton, and M. Michel Chasles; but for a discussion of the subject recourse must be had to the article PORISM. Here it will be sufficient to state Simson's definition, which is,—"A porism is a proposition in which it is proposed to demonstrate that one or more things are given, between which and every one of innumerable other things, not given but assumed according to a given law, a certain relation, described in the proposition, is to be shown to take place;" and to refer to Simson's *Opera Reliqua;* Playfair's paper *On the Origin and Investigation of Porisms;* Trail's *Life of Dr. Simson;* Breton's *Recherches Nouvelles sur les Porismes d'Euclide*, and his *Question des Porismes;* Vincent's *Considérations sur les Porismes;* and Chasles's *Les Trois Livres de Porismes d'Euclide*.

2. Two books are mentioned, named Τόπων πρὸς ἐπιφανείᾳ, which is rendered *Locorum ad Superficiem* by Commandine and subsequent geometers. These books were subservient to the analysis of loci, but the four lemmas which refer to them, and which occur at the end of the seventh book of the *Mathematical Collection*, throw very little light on their contents. Simson's opinion was that they treated of curves of double curvature, and he intended at one time to write a treatise on the subject. (See Trail's *Life*, pp. 60–62, 100–105.)

3. Pappus says that Euclid wrote four books on the *Conic Sections* (βιβλία τέσσαρα Κωνικῶν), which Apollonius amplified, and to which he added other four. It is known that, in the time of Euclid, the parabola was considered as the section of a right-angled cone, the ellipse that of an acute-angled cone, the hyperbola that of an obtuse-angled cone, and that Apollonius was the first who showed that the three sections could be obtained from any cone. There is good ground therefore for supposing that the first four books of Apollonius's *Conics*, which are still extant, resemble Euclid's *Conics* even less than Euclid's *Elements* do those of Eudoxus and Theætetus.

4. A book on *Fallacies* (Περὶ ψευδαρίων) is mentioned by Proclus, who says that Euclid wrote it for the purpose of exercising beginners in the detection of errors in reasoning.

This notice of Euclid would be incomplete without some account of the earliest and the most important editions of his works. Passing over the commentators of the Alexandrian school, the first European translator of any part of Euclid is Boetius (500 A.D.), author of the *De Consolatione Philosophiæ*. His *Euclidis Megarensis Geometriæ libri duo* contain nearly all the definitions of the first three books of the *Elements*, the postulates, and most of the axioms. The enunciations, with diagrams but no proofs, are given of most of the propositions in the first, second, and fourth books, and a few from the third.

Some centuries afterwards, Euclid was translated into Arabic, but the only printed version in that language is the one made of the thirteen books of the *Elements* by Nasir Al-Dín Al-Túsí (13th century), which appeared at Rome in 1594. Judging from the unusual number of diagrams in this edition, the translation of Euclid's text is probably rather free.

The first printed edition of Euclid was a translation of the fifteen books of the *Elements* from the Arabic, made, it is supposed, by Adelard of Bath (12th century), with the comments of Campanus of Novara. It appeared at Venice in 1482, printed by Erhardus Ratdolt, and dedicated to the doge Giovanni Mocenigo. This edition represents Euclid very inadequately; the comments are often foolish, propositions are sometimes omitted, sometimes joined together, useless cases are interpolated, and now and then Euclid's order changed.

The first printed translation from the Greek is that of Bartholomew Zamberti, which appeared at Venice in 1505. Its contents will be seen from the title: *Euclidis megarēsis philosophi platonici Mathematicarųʒ disciplinarū Janitoris: Habent in hoc volumine quicūqʒ ad mathematicā substantiā aspirāt: elemētorum libros xiii cū expositione Theonis insignis mathematici . . . Quibus . . . adjuncta. Deputatum scilicet Euclidi volumē xiiii cū expositiōe Hypsi. Alex. Itidēqʒ Phaeno. Specu. Perspe. cum expositione Theonis. ac Mirandus ille liber Datorum cum expositiōe Pappi Mechanici una cū Marini dialectici protheoria. Bar. Zāber. Vene. Interp̄te.*

The first printed Greek text was published at Basel, in 1533, with the title Εὐκλείνδου Στοιχείων βιβλ. ιέ ἐκ τῶν Θέωνος συνουσιῶν. It was edited by Simon Grynæus from two MSS. sent to him, the one from Venice by Lazarus

Bayfius, and the other from Paris by John Ruellius. The four books of Proclus's commentary are given at the end from an Oxford MS. supplied by John Claymundus.

The English edition, the only one which contains all the extant works attributed to Euclid, is that of Dr. David Gregory, published at Oxford in 1703, with the title, *Εὐκλείδου τὰ σωζόμενα. Euclidis quæ supersunt omnia.* The text is that of the Basel edition, corrected from the MSS. bequeathed by Sir Henry Savile, and from Savile's annotations on his own copy. The Latin translation, which accompanies the Greek on the same page, is for the most part that of Commandine.

The French edition has the title, *Les Oeuvres d'Euclide, traduites en Latin et en Français, d'après un manuscrit très-ancien qui était resté inconnu jusqu' à nos jours. Par F. Peyrard, Traducteur des oeuvres d'Archimède.* It was published at Paris in three volumes, the first of which appeared in 1814, the second in 1816, and the third in 1818. It contains the *Elements* and the *Data*, which are, says the editor, certainly the only works which remain to us of this ever-celebrated geometer. The texts of the Basel and Oxford editions were collated with 23 MSS., one of which belonged to the library of the Vatican, but had been sent to Paris by the Comte de Peluse (Monge). The Vatican MS. was supposed to date from the 9th century; and to its readings Peyrard gave the greatest weight.

What may be called the German edition has the title *Εὐκλείδου Στοιχεῖα. Euclides Elementa ex optimis libris in usum Tironum Græca edita ab Ernesto Ferdinando August.* It was published at Berlin in two parts, the first of which appeared in 1826, and the second in 1829. All the above-mentioned texts were collated with three other MSS.

Of translations of the *Elements* into modern languages the number is very large. The first English translation, published at London in 1570, has the title, *The Elements of Geometrie of the most auncient Philosopher Euclide of Megara. Faithfully (now first) translated into the Englishe toung, by H. Billingsley, Citizen of London. Whereunto are annexed certaine Scholies, Annotations, and Inventions, of the best Mathematiciens, both of time past, and in this our age.* The first French translation of the whole of the *Elements* has the title, *Les Quinze Livres des Elements d'Euclide. Traduicts de Latin en François. Par D. Henrion, Mathematicien.* The first edition of it was printed in 1614, and a second, corrected and augmented, was published at Paris in 1623. An Italian translation, with the title, *Euclide Megarense acutissimo philosopho solo introduttore delle Scientie Mathematice. Diligentemente rassettato, et alla integrità ridotto, per il degno professore di tal Scientie Nicolò Tartalea Brisciano,* was published at Venice in 1569; a Spanish version, *Los Seis Libros primeros de la geometria de Euclides. Traduzidos en lēgua Española por Rodrigo Çamorano, Astrologo y Mathematico,* at Seville in 1576; and a Turkish one at Bulak in 1825. Dr. Robert Simson's editions of the first six and the eleventh and twelfth books of the *Elements*, and of the *Data*, which form the basis of all the modern school texts of Euclid, are so common that it is not considered necessary to describe them.

Authorities.—The authors and editions above referred to; Fabricii *Bibliotheca Græca*, vol. iv.; Murhard's *Literatur der Mathematischen Wissenschaften;* Heilbronner's *Historia Matheseos Universæ;* De Morgan's article "Eucleides" in Smith's *Dictionary of Biography and Mythology.* (J. S. M.)

EUCLID, of Megara, a Greek philosopher, the founder of the Megarian school, was born in the latter half of the 5th century B.C., probably at Megara, though Gela in Sicily has also been named as his birth-place. He was one of the most devoted of the disciples of Socrates. If we may believe Aulus Gellius, such was his enthusiasm that, when a decree was passed forbidding the Megarians to enter Athens, he regularly visited his master by night in the disguise of a woman; and he was one of the little band of intimate friends who had the privilege of listening to the hero's last discourse. After his master's death, he withdrew, with a number of his fellow-disciples, to Megara; and it has been conjectured, though there is no direct evidence, that this was the period of Plato's residence in Megara, of which indications appear in the *Theætetus.* The fundamental principle of Euclid's philosophy was a combination of the Eleatic conception of Being—the One and All, and the Socratic conception of the Good. Being is immaterial and unchangeable, and is identical with the Good, which is the same as God, as Reason, and (following the Socratic doctrine) as Wisdom, and which alone truly exists. Thus the existence of evil was denied; and the main object of the Megarian, as it was of the Eleatic dialectic, was to prove the conceptions of division, number, becoming, motion, and possibility to be self-contradictory and false. With Plato, Euclid taught that sense has cognizance of the changeable and unreal only, while thought penetrates to unchangeable Being, to the Good. The Megarian school prided itself first of all upon its dialectic. Euclid's dialectic differed greatly from that of his master Socrates, in marked contrast to whom he repudiated the principle of analogical reasoning as unsound. His favorite method of attacking an opponent was by the *reductio ad absurdum*, which was also a favorite method with his followers, whose arguments degenerated into trivial sophisms, which laid them frequently open to an attack with their own weapon, and which earned for them the contemptuous name of the Ἐριστικοὶ or "wranglers." Of Euclid's followers the chief were Eubulides, who taught Demosthenes, wrote against Aristotle, and invented several trifling but ingenious paradoxes, of which the most famous is the *Sorites;* Diodorus Chronus, the author of certain arguments to prove the impossibility of motion; Philo; and, most famous of all, Stilpo, who was distinguished by the attractiveness of his lectures.

Our knowledge of Euclid's philosophy is borrowed from scattered passages in Plato, and from Diogenes Laertius. See Zeller, *Socrates and the Socratic Schools;* Dyeck, *De Megaricorum Doctrina* (Bonn, 1827); Mallet, *Histoire de l'École de Mégare* (Paris, 1845); Ritter, *Ueber die Philosophie der Meg. Schule;* Prantl, *Geschichte der Logik*, i., 33; Henne, *L'École de Mégare* (Paris, 1843).

EUDOCIA, the wife of Theodosius II., was the daughter of the Athenian sophist Leontius, or Leon. It is impossible to fix the date of her birth more precisely than in the last decade of the 4th century, though by an inference from a statement of Nicephorus Callistus (xiv. 50) the year 393–4 has been fixed upon. She was called Athenais prior to her conversion to Christianity. By her father she was carefully instructed in literature and the sciences; and so high an estimate did the philosopher form of her beauty and merit that, thinking any other endowment unnecessary, he divided his whole patrimony between his two sons. Athenais, however, resented this as an injustice, and carried her plea to Constantinople before the emperor. Here she gained access to Pulcheria, the sister of Theodosius, and by her she was secretly destined to be the wife of the emperor. The probable date of her marriage is 421. Before her elevation to the throne, she renounced paganism and was baptized. It was not, however, till the birth of a daughter that she received the title of Augusta (423). Her brothers she not only forgave, but raised to the dignity of consuls and præfects. About 438 Eudocia made an ostentatious pilgrimage to the Holy Land, distributing alms and donations for pious purposes with a munificence which exceeded that of the great Helena, and she returned to Constantinople in the following year with precious relics of St. Stephen, St. Peter, and the Virgin. Her peace, however, was soon after disturbed by the jealousy of her husband, on account, it is said, of his observing a beautiful apple which he had presented to her in the hands of Paulinus, his master of the offices. The execution of the supposed favorite, and the retirement of Eudocia in 449 to Jerusalem, did not appease the anger of the emperor, who despatched a messenger for the purpose of putting to death two ecclesiastics who had gained her confidence. The assassination of his envoy provoked the emperor still further, and Eudocia was stripped of her royal honors, and degraded in the eyes of the nation. In Jerusalem Eudocia became infected with the Eutychian heresy, and through her influence it made considerable progress in Syria, but the misfortunes of her daughter Licinia Eudocia led her to obtain a reconciliation with Pulcheria, and through her mediation and that of her brothers she afterwards returned to the communion of the church. She died at Jerusalem about 460, and was buried in the church of St. Stephen With her latest breath she protested that she had never transgressed the bounds of innocence and friendship. Eudocia continued through life to cultivate her early literary tastes. She composed a paraphrase on the Octateuch in heroic verse, a paraphrase of Daniel and Zechariah, and a poem on the martyrdom of St. Cyprian. To these are added a poem on her husband's victory over the Persians, and according to Zonaras, a cento of the verses of Homer applied to the life and miracles of Christ, but her authorship of the latter is generally disputed by critics.

EUDOCIA AUGUSTA, of Macrembolis, lived in the second half of the 11th century. She was the wife of the emperor Constantine XI., and after his death of Romanus IV. She had sworn to her first husband on his death-bed not to marry again, and had even imprisoned and exiled Romanus, who was suspected of aspiring to the throne. Perceiving, however, that she was not able unaided to avert the invasions which threatened the eastern frontier of the empire, she revoked her oath, married Romanus, and with his assistance dispelled the impending danger. She did not live very happily with her new husband, who was warlike and self-willed, and when he was taken prisoner by the Turks she was compelled to vacate the throne in favor of her son Michael and retire to a convent, where she died at an advanced age. She compiled a dictionary of mythology entitled Ἰωνιά (*Collection of Violets*), which has been published by Villoison in his *Anecdota Græca*, Venice, 1781.

EUDOXUS, a physical philosopher, was a native of Cnidus, and flourished about the middle of the 4th century B.C. It is chiefly in his quality of astronomer that his name has descended to our times. What particular service he rendered to that science beyond introducing the Egyptian sphere into Greece, and correcting the length of the year, cannot now be ascertained. Of his personal history it is known, from a life by Diogenes Laertius, that he studied at Athens, under Plato, but being dismissed by that philosopher, passed over into Egypt, where he remained for sixteen months, and that he then went to Cyzicus and the Propontis, where he taught physics, and ultimately migrated with a band of pupils to Athens, where he died in the fifty-third year of his age. Eudoxus is frequently referred to by ancient writers. Strabo attributes to him the introduction of the odd quarter day into the year. According to Vitruvius he invented a solar dial. The *Phænomena* of Aratus is a poetical account of the astronomical observations of Eudoxus. Several works have been attributed to him, but they are all lost.

EUDOXUS, of Cyzicus, a Greek navigator who flourished about 130 B.C. He was employed by Ptolemy Euergetes to make a voyage to India. After two of these he circumnavigated Africa from the Red Sea to Gades. An attempt to make the return voyage was unsuccessful.

EUGENE, FRANÇOIS (1663–1736), commonly called PRINCE EUGENE OF SAVOY, one of the greatest generals of his time, born at Paris on the 18th October, 1663, was the fifth son of Eugene Maurice, count of Soissons, who was grandson of the Duke of Savoy, Charles Emmanuel I., and of Olympia Mancini, niece of Cardinal Mazarin. Originally destined for the church, Eugene was known at court as the *petit abbé;* but his own predilection was strongly for the army. His mother, however, had fallen into disgrace at court, and his application for a commission, repeated more than once, was refused by the king, Louis XIV., prompted probably by the minister Louvois. This engendered in him what proved to be a life-long resentment against the king and his native country. Having quitted France in disgust, he proceeded to Vienna, where the emperor Leopold, who was allied to his family, received him kindly, and granted him permission, along with several other Frenchmen of distinction, to serve against the Turks under the banners of Austria. His first campaign was that of 1683, in which he so distinguished himself that the emperor gave him the command of a regiment of dragoons. After several other campaigns he became major-general; and it was in that capacity that he served at the siege of Belgrade in 1688. At the instigation of Louvois, a decree of banishment from France was now issued against all Frenchmen who should continue to serve in foreign armies. "I shall return into France in spite of him," said Eugene, when the news was communicated to him; and he continued his brilliant career in foreign service, one great stimulus to his ambition being the hope that he might be able to enter his native country as an invader.

Prince Eugene's next employment was in a service that required diplomatic as well as military skill. He was sent by the emperor Leopold to Italy with the view of binding the duke of Savoy to the coalition against France, and of co-operating with the Italian and Spanish troops. The first engagement with Catinat at Staffarde resulted in the defeat of the coalition; but in the spring of 1691 Prince Eugene, having secured reinforcements, caused the siege of Coni to be raised, took possession of Carmagnole, and in the end completely defeated Catinat. He followed up his success by entering Dauphiné, where he took possession of Embrun and Gap. After another campaign, in which there was little eventful, the further prosecution of the war was abandoned owing to the defection of the duke of Savoy from the coalition, and Prince Eugene returned to Vienna, where he soon afterwards received the command of the army in Hungary.

It was about this time that Louis XIV. secretly offered him the baton of a marshal of France, with the government of Champagne which his father had held, and also a pension of two thousand pistoles. But Eugene rejected these offers with indignation, and proceeded to combat the Turks commanded by the Sultan Kara-Mustapha in person. After some able marches and skilful manœuvres, he surprised the enemy (September 11, 1697) at Zentha, on the Theiss, in a camp retrenched *en tête de pont;* and, after an attack as vigorous as it was daring, he killed twenty thousand of them, drove ten thousand into the river, made prisoners of the remainder, and took the whole of their artillery and baggage. The victory was one of the most complete and important ever won by the Austrian arms. The earlier historians and biographers of Prince Eugene have generally stated that the battle of Zentha was fought against express orders from the court of Vienna, that Eugene was placed under arrest for violating these orders, and that a proposal to bring him before a council of war was frustrated only by the threatening attitude assumed by the citizens of Vienna. It is somewhat curious that a story so minute in its details should, as is now agreed on all hands, be utterly devoid of foundation. It is in fact so pure a fabrication that the latest biographers do not even allude to it. Immediately after the battle Eugene returned to Hungary; and, after a campaign distinguished by no remarkable event, a treaty of peace was at length concluded with the Turks at Carlowitz, on the 26th January, 1699.

Prince Eugene's next opportunity of distinguishing himself in active service came in the war of the Spanish succession. At the commencement of the year 1701, he was sent into Italy once more to oppose his old antagonist Catinat. He achieved a rapid success, forcing the French army, after sustaining several checks, to retire behind the Oglio, where a series of reverses equally unexpected and severe led to the recall of Catinat in disgrace. The duke of Villeroi, an utterly inexperienced general who succeeded to the command of which Catinat had been deprived, having ventured to attack Eugene at Chiari, in an impregnable position, was repulsed with great loss. And this first check was only the forerunner of more signal reverses; for, in a short time, Villeroi was forced to abandon the whole of the Mantuan territory, and to take refuge in Cremona, where he seems to have considered himself as secure in the midst of his staff. By means of a stratagem, however, Eugene penetrated into the city during the night, at the head of 2000 men, and, though he found it impossible to hold the town, succeeded in carrying off Villeroi as a prisoner. But as the duke of Vendôme, a much abler general, replaced the captive, the incursion, daring though it was, proved anything but advantageous to the Austrians. The superior generalship of his new opponent, and the fact that the French army had been largely reinforced, while reinforcements had not been sent from Vienna, forced Prince Eugene to confine himself to a war of observation, without important results, though fertile in most useful lessons to students of military science. This campaign was terminated by the sanguinary battle of Luzara, fought on the 1st of August, 1702, in which each party claimed the victory. Both armies having entered into winter quarters, Eugene returned to Vienna, where he was appointed president of the council of war. He then set out for Hungary in order to combat the insurgents in that country; but his means proving insufficient, he effected nothing of importance. The revolt, was, however, put down by the success which General Heister obtained in another quarter. Prince Eugene accordingly proceeded to Bavaria, where, in 1704, he made his first campaign along with Marlborough. Similarity of tastes, views, and talents soon established between these two great men a friendship which is rarely to be found amongst military chiefs, and which contributed, more than all other causes put together, to the success which the allies obtained. The first and perhaps the most important of these successes was that of Höchstädt or Blenheim, gained on the 3d of August, 1704, where the English and imperial troops triumphed over one of the finest armies that France had ever sent into Germany.

But since Prince Eugene had quitted Italy, Vendôme, who commanded the French army in that country, had obtained various successes against the duke of Savoy, who had once more deserted France and joined Austria. The emperor deemed the crisis so serious that he recalled Eugene and sent him to Italy to the assistance of his ally. Vendôme at first opposed great obstacles to the plan which the prince had formed for carrying succors into Piedmont; but after a variety of marches and counter-marches, in which both commanders displayed signal ability, the two armies met at Cassano (August 16, 1705), where a deadly engagement ensued, and Prince Eugene received two severe wounds, which forced him to quit the field. This accident decided the fate of the battle, and for the time suspended the prince's march towards Piedmont. Vendôme, however, was recalled, and La Feuillade (who succeeded him) was incapable of long arresting the progress of such a commander as Eugene. After once more passing several rivers in presence of the French army, and executing one of the most skilful and daring marches he had ever performed, the latter appeared before the entrenched camp at Turin, which place the French were now besieging with an army eighty thousand strong. Prince Eugene had only thirty thousand men; but his antagonist was the duke of Orleans, who, though full of zeal and courage, wanted experience. Besides, by a secret order of Louis XIV., who had, in fact, transferred the command to Marsin, the young prince was restricted to the execution of an ill-conceived plan, which neutralized the advantage of superior numbers, and put it in the power of the enemy to select his point of attack. With equal courage and address, Eugene profited by the misunderstanding which the exhibition of such an order could not fail to produce between the French generals; and having on the 7th September, 1706, attacked the French army in its entrenchments, he gained a complete victory, which decided the fate of Italy. This brilliant achievement, the result of the most masterly combinations, and in several respects the prototype of the campaign of Marengo in 1800, affords one of the most remarkable examples of the difficulty of defending extensive lines even against an inferior army, massed upon one or two points. As soon as the duke of Orleans observed the imperial army approaching, he wished to march out of the lines with the whole French army, and to deliver battle in the open field, where he could have availed himself of his great numerical superiority, but he was restrained by Marsin, who, by this absurd interposition, sealed the fate of the French army, and lost Italy. In the heat of the battle Eugene received a wound, and was thrown from his horse into a ditch. As a recompense for so important services the prince received the government of the Milanese, of which he took possession with great pomp on the 16th April, 1707.

The attempt which he made against Toulon in the course of the same year failed completely, because the invasion of the kingdom of Naples retarded the march of the troops which were to have been employed in it, and this delay afforded Marshal de Tessé time to make good dispositions. Obliged to renounce his project, therefore, the prince repaired to Vienna, where he was received with great enthusiasm both by the people and by the court. "I am very well satisfied with you," said the emperor, "excepting on one point only, which is, that you expose yourself too much." This monarch immediately despatched Eugene to Holland, and to the different courts of Germany, in order to forward the necessary preparations for the campaign of the following year, 1708.

Early in the spring of 1708 the prince proceeded to Flanders, in order to assume the command of the forces which his diplomatic ability had been mainly instrumental in assembling. This campaign was opened by the victory of Oudenarde, to which the perfect union of Marlborough and Eugene on the one hand, and the misunderstanding between Vendôme and the duke of Burgundy on the other, seem to have equally contributed. The duke immediately abandoned the Low Countries, and remaining in observation made no attempt whatever to raise the siege of Lille, where Boufflers distinguished himself by a glorious defence. To the valor of the latter Eugene paid a flattering tribute, and invited him to prepare the articles of capitulation himself, with the words, "I subscribe to everything beforehand, well persuaded that you will not insert anything unworthy of yourself or of me." After this important conquest, Eugene and Marlborough proceeded to the Hague, where they were received in the most flattering manner by the public, by the states-general, and, above all, by their esteemed friend the pensionary Heinsius. Negotiations were then opened for peace, but proved fruitless. The campaign of 1709 was opened in Flanders by two hostile armies, each a hundred and fifty thousand strong. That of the French was commanded by Villars, who, fearing to compromise himself in opposition to such great captains as Marlborough and Eugene, remained upon the defensive, and suffered them to take Tournay without opposition. Having gone to succor Mons he was followed by the allies, who attacked him at Malplaquet on the 9th of September, in a formidable position, where he had had time to entrench himself. The attack was made with equal vigor and ability; but owing to the strength of the French position, and the tenacity with which it was maintained, the victory was purchased at the cost of twenty-five thousand men killed on the field of battle, and the Dutch infantry was almost annihilated. Although the allies remained masters of the field of battle, this barren advantage had been so dearly bought that they found themselves soon afterwards out of all condition to undertake anything. Their army accordingly went into winter quarters, and Prince Eugene returned to Vienna, whence the emperor almost immediately despatched him to Berlin. From the king of Prussia the prince obtained everything which he had been instructed to require; and having thus fulfilled his mission, he returned into Flanders, where, excepting the capture of Douai, Bethune, and Aire, the campaign of 1710 presented nothing remarkable. On the death of the emperor Joseph I. in April, 1711, Prince Eugene, in concert with the empress, exerted his utmost endeavors to secure the crown to the archduke, who afterwards ascended the imperial throne under the name of Charles VI. In the same year the changes which had occurred in the policy, or rather the caprice, of Queen Anne, brought about an approximation between England and France, and put an end to the influence which Marlborough had hitherto possessed. When this political revolution became known, Prince Eugene immediately repaired to London, charged with a mission from the emperor to re-establish the credit of his illustrious companion in arms, as well as to re-attach England to the coalition. The mission having proved unsuccessful, the emperor found himself under the necessity of making the campaign of 1712 with the aid of the Dutch alone. The defection of the English, however, did not induce Prince Eugene to abandon his favorite plan of invading France. He resolved, at whatever cost, to penetrate into Champagne; and in order to support his operations by the possession of some important places, he began by making himself master of Quesnoy. But the Dutch, having been surprised and beaten in the lines of Denain, where Prince Eugene had placed them at too great a distance to receive timely support in case of an attack, he was obliged to raise the siege of Landrecies, and to abandon the project which he had so long cherished. This was the last campaign in which Austria acted in conjunction with her allies. Abandoned first by England and then by Holland, the emperor, notwithstanding these desertions, still wished to maintain the war in Germany; but the superiority of the French army prevented Eugene from relieving either Landau or Freiburg, which were successively obliged to capitulate; and seeing the empire thus laid open to the armies of France, and even the hereditary states themselves exposed to invasion, the prince counselled his master to make peace. Sensible of the prudence of this advice, the emperor immediately entrusted Eugene with full powers to negotiate a treaty of peace, which was concluded at Rastadt, on the 6th of March, 1714. On his return to Vienna Prince Eugene was employed for a time in matters of internal administration; but it was not long before he was again called on to assume the command of the army in the field. In the spring of 1716 the emperor, having concluded an offensive alliance with Venice against Turkey, appointed Eugene to command the army of Hungary; and at Peterwaradin, with a force not exceeding sixty thousand men, he gained (5th August, 1716) a signal victory over the Turks, who had not less than a hundred and fifty thousand men in the field. In recognition of this service to Christendom the pope sent to the victorious general the consecrated rapier which the court of Rome was accustomed to bestow upon those who had triumphed over the infidels. But the ensuing campaign, that of 1717, was still more remarkable on account of the battle of Belgrade. After having besieged the city for a month he found himself in a most critical, if not hopeless, situation. The force opposed to him numbered six times his own army, which besides was become smaller every day, owing to the prevalence of dysentery. In these circumstances the only possible deliverance was by a bold and decided stroke. Accordingly on the morning of the 16th August, 1717, Prince Eugene ordered a general attack, which resulted in the total defeat of the enemy with an enormous loss, and in the capitulation of the city six days afterwards. The prince was wounded in the heat of the action, this being the thirteenth time that he had been hit upon the field of battle. On his return to Vienna he received, among other testimonies of gratitude, a sword valued at eighty thousand florins from the emperor. In the following year, 1718, after some fruitless negotiations with a view to the conclusion of peace, he again took the field; but the treaty of Passarowitz (21st July, 1718) put an end to hostilities at the moment when the prince had well-founded hopes of obtaining still more important successes than those of the last campaign, and even of reaching Constantinople, and dictating a peace on the shores of the Bosphorus.

As the government of the Netherlands, formerly conferred upon Eugene, had now for some reason been bestowed on a sister of the emperor, the prince was appointed vicar-general of Italy, with a pension of three hundred thousand florins. Though still retaining his official position and much of his influence at court, his personal relations with the emperor were not so cordial as before, and he suffered from the intrigues of the anti-German party. During the ten years of peace which ensued, Eugene occupied himself with the arts and with literature, to which he had hitherto been able to devote little of his time. This new interest led him to correspond with many of the most eminent men in Europe. But the contest which arose out of the succession of Augustus II. to the throne of Poland having afforded Austria a pretext for attacking France, war was resolved on, contrary to the advice of Eugene. In spite of this, however, he was appointed to command the army destined to act upon the Rhine, which from the commencement had very superior forces opposed to it; and if it could not prevent the capture of Philipsburg after a long siege, it at least prevented the enemy from entering Bavaria. Prince Eugene having now attained his seventy-first year, no longer possessed the vigor and activity necessary for a general in the field, and he welcomed the peace which was concluded on the 3d of October, 1735. On his return to Vienna, his health declined more and more, and he died in that capital on the 21st April, 1736, leaving an immense inheritance to his niece the Princess Victoria of Savoy.

Of a character cold and severe, Prince Eugene had almost no other passion than that of glory. He died unmarried, and seemed so little susceptible to female influence that he was styled a Mars without a Venus. Although one of the greatest generals of his time, military science is not indebted to him for any remarkable improvement. His operations were not directed according to any positive method, nor conformable to invariable principles; it was by sudden inspirations, and an admirable rapidity of *coup d'œil*, that he conducted himself on the ground according to the circumstances and the men he had to deal with; and upon all occasions he took the greatest pains to ascertain the character of the generals who were opposed to him. Despising the lives of his soldiers as much as he exposed his own, it was always by persevering efforts and great sacrifices that he obtained victory. His almost invariable success raised the reputation of the Austrian army to a point which it has never reached either before or since his day. War was with him a passion. Always on the march, in camps, or on the field of battle during more than fifty years, and under the reign of three emperors, he had scarcely passed two years together without fighting. Prince Eugene was a man of the middle size, but, upon the whole, well made; the cast of his visage was somewhat long, his mouth moderate, and almost always open; his eyes were black and animated, and his complexion such as became a warrior. His funeral oration, composed in Italian by Cardinal Passionei, was translated into French by Madame du Boccage, 1759.

See *Histoire du Prince Eugène* (Amst., 1740, Vienna, 1755) by Mauvillon, published anonymously; *Histoire Militaire du Prince Eugène, du Duc de Marlborough, et du Prince du Nassau*, by Dumont (Hague, 1729); *Prinz Eugen von Savoyen*, by Von Arneth (3 vols., Vienna, 1858–9); *Prinz Eugen von Savoyen*, by Von Sybel (London, 1868).

EUGENIUS, the name of four popes.

Eugenius I. was a native of Rome. Elected pope in 654, on the banishment of Martin I. by the emperor Constans II., he showed greater deference than his predecessor to the emperor's wishes, and made no public stand against the patriarchs of Constantinople. He died in 657, and was canonized, his day being the 2d of June, although according to Anastasius, he died on the 1st of that month.

Eugenius II. was a native of Rome, and was chosen to succeed Pascal I. in 824. Another candidate, Zinzinnus, was proposed by the plebeian faction, and the presence of the emperor Lothair was necessary in order to maintain the authority of the new pope. Lothair took advantage of this opportunity to redress many abuses in the papal administration, to vest the election of the pope in the nobles, and to confirm the statute that no pope should be consecrated till his election had the approval of the emperor. A council which assembled at Rome during the reign of Eugenius passed several enactments for the restoration of church discipline, took measures for the foundation of schools and chapters, and decided against priests wearing a secular dress or engaging in secular occupations. Eugenius also adopted various provisions for the care of the poor and of widows and orphans, and on that account received the name of "father of the people," an epithet not altogether appropriate, if he was, as he is said to have been, the author of the "ordeal of cold water." He died in 827.

Eugenius III., a native of Pisa, was elected pope in February, 1145. When called to occupy this supreme position he was only abbot of the Cistercians, and he owed his elevation partly to the fact that none were eager to accept an office the duties of which were at the time so difficult and dangerous, but chiefly to his being the friend and pupil of Bernard of Clairvaux, the most influential ecclesiastic of the Western church, and a strong assertor of the pope's temporal authority. The choice had not, however, the approval of Bernard, who remonstrated against the election on account of the "innocence and simplicity" of Eugenius; but after the choice was made he took advantage of the qualities in Eugenius which he objected to, so as virtually to rule in his name. During nearly the whole of his pontificate Eugenius was unable to reside in Rome. Hardly had he left the city to be consecrated in the monastery of Farfa, when the citizens, under the influence of Arnold of Bresica—the great opponent of the pope's temporal power—established the old Roman constitution, and elected Giordano to be "patrician." Eugenius appealed for help to Tivoli and to other cities at feud with Rome, and with their aid was successful in making such conditions with the Roman citizens as enabled him for a time to hold the semblance of authority in his capital; but as he would not agree to a treacherous compact against Tivoli, he was compelled to leave the city in March, 1146. He stayed for some time at Viterbo and then at Sienna, but ultimately went to France. On hearing of the fall of Edessa, he had, in December, 1145, addressed a letter to Louis VII. of France, calling on him to take part in another crusade; and at a great diet held at Spires in 1146 the emperor Conrad III. also, and many of his nobles were, by the eloquence of Bernard, incited to dedicate themselves to the holy warfare. After holding councils at Paris, Rheims, and Trèves, Eugenius, in 1149, returned to Italy, and took up his residence at Viterbo. In 1150, through the aid of the king of Sicily, he was able again to enter Rome, but the jealousy of the republicans soon compelled him to retire. The emperor Frederick Barbarossa had promised to aid him against his revolted subjects, but the death of Eugenius, at Tivoli, June 7, 1153, prevented the fulfilment of the engagement. Though the citizens of Rome were jealous of the efforts of Eugenius to assert his temporal authority, they were always ready to recognize him as their spiritual lord, and they besides deeply reverenced his personal character. Accordingly he was buried at the Vatican with every mark of respect, and his tomb soon acquired an extraordinary fame for miraculous cures.

EUGENIUS IV. (1383–1447), born in 1383, was the son of a Venetian merchant, and bore the name of Gabriel Condolmieri. His mother was the sister of Gregory XII., and when Gregory mounted the papal throne in 1406, Gabriel, then a Celestine monk, became bishop of Sienna. In 1408 he was made cardinal, and on the death of Martin V. he was elected pope, March 3, 1431. Martin V. belonged to the house of Colonna, and the rich treasures which he had accumulated during his pontificate remained in their hands. Eugenius, however, claimed their possession, as the papal successor of Martin, and this being refused, he, with the aid of the rival faction of the Orsini and the general body of the Roman citizens, seized all the Colonnas who were in Rome, captured their castles in the surrounding country, and compelled the prince of Salerno to make humiliating terms. With the large sum of money acquired from the Colonnas he was enabled soon afterwards to quell a revolt which had assumed serious dimensions in the Roman states, and for a time his power was undisputed throughout all his dominions. The augury thus presented of a pontificate of exceptional prosperity and influence was not, however, fulfilled, for the after career of Eugenius was chiefly a succession of humiliations, and during the greater part of it there existed the scandal of a church "divided against itself." It is doubtful whether even Martin V., if he had lived, could have longer delayed the serious quarrel between pope and council which was the chief feature of Eugenius's pontificate; but the latter had neither his predecessor's family influence; nor his practical prudence, personal popularity, or steadfast will. He was a patron and friend of learning, and is admitted to have practised with exemplary conscientiousness all the virtues of his order, but he can scarcely be allowed any other commendation. At times he manifested a certain degree of dexterity in gaining his end, but as he was ignorant of the world, and unable to appreciate the motives and interests which exist beyond the pale of a monastery, he was in a great measure necessarily deprived of the knowledge which could guide him safely through complicated circumstances. In addition to this he was a strong and hard dogmatist, bitter and relentless in his hatred of heresy, and keenly suspicious of anything that in the faintest way seemed to cast a doubt on the dignity, infallibility, and unlimited authority of his office. On the very day that he was chosen pope the council appointed by his predecessor met at Basel. Three principal subjects were to engage its attention,—the reconciliation of the Hussites, the reform of the church, and the reunion of the Greek and Latin churches. A great victory gained by the Hussites a few weeks after the council met seemed, in the opinion of the majority of the members, to lend to the two former subjects an additional and supreme urgency, and they actually arranged to receive a deputation of the Hussites for the purpose of agreeing to a peaceable settlement of the points in dispute. Such a proposal, however, at once excited the alarm of Eugenius,—alarm regarding his own authority, and alarm at the manifestation of such signs of clemency towards heretics. His fears were doubtless nourished by the Roman curia, who foresaw the injury that would result to their own interests through the threatened reforms; and on November 12, induced partly by his own misgivings and partly by their advice, Eugenius wrote the cardinal Cæsarini, president of the council, ordering him to dissolve it, and summon another to meet two years afterwards at Bologna. Against this command Cæsarini strongly remonstrated, but Eugenius was inflexible, and the council, obtaining the support of the emperor and the duke of Milan, proceeded to act independently of the pope's authority. He fulminated letters of excommunication against all who should attend it, but the number of its members went on increasing; and, gaining confidence by its accessions, it cited him on April 20, 1432, to appear before it in less than three months, and on September 6, as he did not obey the summons, declared him guilty of schism. Eugenius, to gain the support of Sigismund, had granted him the imperial crown, but since Sigismund remained faithful to the council, Eugenius was compelled to yield, and in 1433 he revoked his bull of dissolution. In the following year the Colonnas, aided by the Visconti, compelled Eugenius to flee from Rome. He escaped in disguise to Florence, and afterwards, notwithstanding an offer of assistance from the patriarch of Alexandria, took up his residence at Bologna. Meantime the essential subjects of dispute between him and the council, so far from being settled, were gradually leading to a crisis, and when finally the council endeavored to deprive him of the power of conferring benefices, he in 1437 sought to change the place of meeting to Ferrara, on the ground that the latter place was more suitable for discussing the reunion with the Greek church. The council replied by summoning him to appear before them within sixty days, at the end of which time they, on his failing to appear, suspended him from his functions. In January 10, 1438, the opposition council, supported by the emperor and the patriarch, met at Ferrara, but on account of an outbreak of the plague, the place of meeting was changed to Florence. Here the act declaring the reunion of the Greek and Latin churches was published July 6, 1439. Meantime, the council at Basel proceeded to elect as pope Amadeus duke of Savoy, under the title of Felix V., and continued the work of reform until 1443. In October of that year Eugenius, with the aid of Alphonso king of Aragon, whose claim to the throne he had supported in opposition to René of Anjou, was enabled to enter Rome; and in 1447, through the subtle but unprincipled craft of Æneas Sylvius Piccolomini, who had forsaken his old master Amadeus, the whole of Germany was induced to declare against the antipope. The same day, however, that news reached Eugenius of this diplomatic triumph, he was seized with a mortal illness; and, after only lingering to sign the treaty of pacification, he died 23d February, 1447. Nor does he appear to have gained much comfort from this final act of his pontificate, regarding it rather as a necessary but disagreeable compromise than as the means of attaining his original purpose, for he is said to have exclaimed on his deathbed,—"O Gabriel, Gabriel, better would it have been for you to have been neither pope, nor cardinal, nor bishop, but to have finished your days as you commenced them, following peaceably in the monastery the exercises of your order."

EUGUBINE or IGUVINE TABLES, *Tabulæ Eugubinæ*, are seven tablets of brass containing a series of sacerdotal inscriptions in the ancient Umbrian language, of inestimable value to the student of Italian linguistic. According to Concioli, they were discovered in 1444 amid the ruins of a theatre in the vicinity of Gubbio (the ancient Eugubium or Iguvium), and according to Passeri, they were bequeathed in 1456 by a private citizen to the public authorities of the town. Considerable doubt exists as to the original number of the tablets. Concioli asserts that nine were discovered, but that two were taken to Venice in 1540 and never brought back; other early notices speak of eight, and even M. Bréal is inclined to hope that the Venetian tablets may yet be recovered. The seven are preserved in the *palazzo municipale* of their native city, and much more truly than Dante's missal-painter Oderisi they form *l'onor di Eugubio*. Taken altogether they furnish 447 lines, for the most part continuous and entire. Tables I., II., V., and VI. are engraved on both sides, but a considerable blank space is left on one side in the case of II. and V., and the back of VII. contains only a few lines. The inscriptions read from right to left; those of V. and VII., and nearly all on the obverse of V., are in Roman letters; the rest, which are pretty certainly of earlier date, are in Etruscan letters. According to M. Bréal, they may be ascribed to the first and second century A.D. For three centuries after their discovery nothing was known as to the contents of the tables: Salmasius confessed he could not even say whether they should be read from right to left or from left to right. The first attempt at divining their meaning was made by Bernardinus Baldus in the beginning of the 17th century, and he was followed by Adrian van Schrieck who believed he had got possession of the oldest monument of the Low German language, and interpreted accordingly. Olivieri recognized the name of Eugubium in one frequently recurring word. Louis Bourget pointed out that one of the tablets written in the Etruscan letters corresponded in the main with two written in Roman letters. C. O. Müller, in his great work *Die Etrusken*, showed that in spite of the use of Etruscan letters the language of the inscriptions was totally different from the Etruscan language. Lepsius added greatly to the epigraphical criticism of the tablets, and Lassen and Grotefend made several successful attempts at interpretation. And finally Aufrecht and Kirchhoff, summing up the labors of their predecessors, and working according to strict scientific method, brought the interpretation of the tables to a degree of perfection that could hardly have been hoped for, though there still remains in matters of detail sufficient scope for such investigators as Bréal, Ebel, Corssen, Ascoli, Zeyss, Savelsberg, and Bugge. The tables contain the acts of a corporation of priests called the Attidian Brethren, who had authority over a considerable region, and probably derived their name from an ancient town Attidium, corresponding to the modern Attigio. The brethren were twelve in number, and acted under the presidency of an *adfertur*. They offered sacrifices to a large number of gods and goddesses—Jupiter, Sancus, Mars, Fisus, Grabovius, Cerfius, Vofionus, Tefer, etc., many of whom are altogether unknown to the classical student, and probably belonged to an indigenous Umbrian cult. Tables VI. and VII. give details of a purification of the Fisian Hill and a lustration of the people of Iguvium; and Table II. furnishes a list of the tribes who had a right to participate in a certain sacrifice.

EULENSPIEGEL, in French *Ulespiegel*, in older English *Howleglas*, one of the most popular of European chapbooks, consisting in all its innumerable rifacimentos of stories of ludicrous roguery, in which the love of fun is not unmingled with the love of mischief. The name in its present form is equivalent to Noctuæ Speculum or Owl's Mirror, and may be compared with such appellations as Schwabenspiegel, Sachsenspiegel, Lalenspiegel, Speculum historiale, Speculum Conversionis Peccatorum, Speculum de Passione Domini nostri Jesu Christi, the Mirror of the World, the Mirror for Magistrates, the Steele Glas, and a hundred others of the same type. It may possibly have arisen early in the Middle Ages, and it is distinctly mentioned in a book *De Generibus Ebriosorum*, or "Concerning the kinds of drunkards," published in 1515. No definitive explanation has been given of the origin of the name, but one interpretation makes it rest on the fact that man recognizes his faults no more than an owl that looks into a mirror, and another finds the original form in the Low German Ul en Spiegel, or Ul den Spiegel, which would signify "Cleanse the looking-glass." The popularity of the book has not only enriched literary German with the words *Eulenspiegelei*, waggery, *Eulenspiegeln*, to play the wag, etc., but it has furnished French with *espiègle* and *espièglerie*. Ben Jonson refers in his *Masque of Fortune* and his *Sad Shepherd* to Owl-glass, Ulenspiegle and Owlspiegle, and Taylor makes a peculiar use of the word when he says—

> "Ride on my best invention like an asse
> To the amazement of each Owliglasse."

According to an old tradition, the tricks and jests of the collection are attributed to a certain Till or Tyll Eulenspiegel, otherwise Till the Saxon or Tylus Saxonicus, who was born at Kneitlingen near Schoppenstadt, in the duchy of Brunswick, and was the son of Claus Eulenspiegel and Anna Wortbeck. He is usually stated to have been buried in 1350 at Mölln, about four leagues from Lubeck, but the people of Damme in Belgium claim that his grave is with them. At Mölln, to quote an old book of travels cited by Nares, the townsmen "yearly keep a feast for his memory, and yet show the apparell he was wont to wear;" and his tomb was adorned with a fantastic effigy, holding in one hand a little tankard with a jack-in-a-box, and in the other a basket full of little mannikins with fool's caps on their heads. That there was such a person as Tyll seems not improbable, but what connection he had with the Owl-glass it is hard to discover: Eulenspiegel at least is pretty certainly a later addition to his name. Mr. William F. Thoms found the Irish peasantry telling stories of *Old Espeel*, and a writer in the *Gentleman's Magazine*, September, 1877, Mr. David Fitzgerald, "met with pretty clear traces of Eulenspiegel in the traditions of the county of Limerick, where he figures as one *Ulas*, whose confession, like that of his prototype, is yet a favorite tale."

The book was originally, it would appear, composed in Low German; and, according to Lappenberg, the High German version printed at Strasburg in 1519 and hitherto regarded as the *editio princeps*, was the work of Thomas Murner the Franciscan monk. A Latin translation was made by Nemius; and another by Periander appeared at Frankfort-on-Maine in 1567 as *Noctuæ Speculum, omnes res memorabiles variasque et admirabiles Tyli Saxonici machinationes complectens.* An English translation called *Howleglas his life*, printed at London by Copeland, is preserved among the Garrick plays in the British Museum; extracts from it are given in W. F. Thoms's *Lays and Legends of various countries: Germany.* French translations appeared at Lyons in 1550, at Orleans, 1571, at Antwerp, 1579, at Rouen, 1701. Delepierre published an edition at Bruges, 1835, and another at Brussels, 1840; and a complete translation into modern French from the 1519 edition was printed at Paris by P. Jannet, 1858. An English edition was published in 1860, under the direction of Kenneth R. H. Mackenzie, and with illustrations by Alfred Crowquill. In 1865 appeared a photolithographic reprint of the Lower Saxon version, originally printed by Servais Kruffter (Servetius Cruftanus). There is no complete copy of the original, but portions in the Royal Library at Vienna and in the Royal Library at Berlin complete each other.

See Görres, *Die deutschen Volksbücher*, 1807; Lappenberg, *Eulenspiegel*, 1854.

EULER, Leonard (1707–1783), one of the most distinguished mathematicians of the 18th century, was born at Basel on the 15th of April, 1707, his father Paul Euler, who had considerable attainments as a mathematician, being Calvinistic pastor of the neighboring village of Riechen. After receiving preliminary instructions in mathematics from his father, he was sent to the university of Basel, where geometry soon became his favorite study. His genius for analytical science gained for him a high place in the esteem of John Bernoulli, who was at that time one of the first mathematicians in Europe, as well as of his sons Daniel and Nicholas Bernoulli. Having taken his degree as master of arts in 1723, Euler afterwards applied himself, at his father's desire, to the study of theology and the Oriental languages, with the view of entering the church, but, with his father's consent, he soon returned to geometry as his principal pursuit. At the same time, by the advice of the younger Bernoullis, who had removed to St. Petersburg in 1725, he applied himself to the study of physiology, to which he made a happy application of his mathematical knowledge; and he also attended the medical lectures of the most eminent professors of Basel. While he was keenly engaged in physiological researches, he composed a dissertation on the nature and propagation of sound, and an answer to a prize-question concerning the masting of ships, to which the French Academy of Sciences adjudged the second rank in the year 1727.

In 1727, on the invitation of Catherine I., Euler took up his residence in St. Petersburg, and was made an associate of the Academy of Sciences. In 1730 he became professor of physics, and in 1733 he succeeded his friend Daniel Bernoulli in the chair of mathematics. At the commencement of his new career he enriched the academical collection with many memoirs, which excited a noble emulation between him and the Bernoullis, though this did not in any way affect their friendship. It was at this time that he carried the integral calculus to a higher degree of perfection, invented the calculation of sines, reduced analytical operations to a greater simplicity, and threw new light on nearly all parts of abstract or pure mathematics. In 1735 a problem proposed by the academy, for the solution of which several eminent mathematicians had demanded the space of some months, was solved by Euler in three days, but the effort threw him into a fever which endangered his life and deprived him of the use of his right eye. The Academy of Sciences at Paris in 1738 adjudged the prize to his memoir on the nature and properties of fire, and in 1740 his treatise on the tides shared the prize with those of Colin Maclaurin and Daniel Bernoulli,—a higher honor than if he had carried it away from inferior rivals.

In 1741 Euler accepted the invitation of Frederick the Great to Berlin, where he was made a member of the Academy of Sciences and professor of mathematics. He enriched the last volume of the *Mélanges* or Miscellanies of Berlin with five memoirs, and these were followed, with an astonishing rapidity, by a great number of important researches, which are scattered throughout the annual memoirs of the Prussian Academy. At the same time he continued his philosophical contributions to the Academy of St. Petersburg, which granted him a pension in 1742. The respect in which he was held by the Russians was strikingly shown in 1760, when a farm he occupied near Charlottenburg happened to be pillaged by the invading Russian army. On its being ascertained that the farm belonged to Euler, the general immediately ordered compensation to be paid, and the empress Elizabeth sent an additional sum of four thousand crowns. In 1766 Euler with difficulty obtained permission from the king of Prussia to return to Petersburg, to which he had been originally invited by Catherine II. Soon after his return to St. Petersburg a cataract formed in his left eye, which ultimately deprived him almost entirely of sight. It was in these circumstances that he dictated to his servant, a tailor's apprentice, who was absolutely devoid of mathematical knowledge, his *Elements of Algebra,* a work which, though purely elementary, displays the mathematical genius of its author, and is still reckoned one of the best works of its class. Another task to which he set himself immediately after his return to St. Petersburg was the preparation of his *Lettres à une Princesse d'Allemagne sur quelques sujects de Physique* (3 vols., 1768–72). They were written at the request of the princess of Anhalt-Dessau, and contain an admirably clear exposition of the principal facts of mechanics, optics, acoustics, and physical astronomy. Theory, however, is frequently unsoundly applied in it, and it is to be observed generally that Euler's strength lay rather in pure than in applied mathematics. In 1755 Euler had been elected a foreign member of the Academy of Sciences at Paris, and some time afterwards the academical prize was adjudged to three of his memoirs *Concerning the Inequalities in the Motions of the Planets.* The two prize-questions proposed by the same academy for 1770 and 1772 were designed to obtain a more perfect theory of the moon's motion. Euler, assisted by his eldest son Johann Albert, was a competitor for these prizes, and obtained both. In the second memoir he reserved for further consideration several inequalities of the moon's motion, which he could not determine in his first theory on account of the complicated calculations in which the method he then employed had engaged him. He afterwards reviewed his whole theory with the assistance of his son and Krafft and Lexell, and pursued his researches until he had constructed the new tables, which appeared, together with the great work, in 1772. Instead of confining himself, as before, to the fruitless integration of three differential equations of the second degree, which are furnished by mathematical principles, he reduced them to the three ordinates which determine the place of the moon; and he divided into classes all the inequalities of that planet, as far as they depend either on the elongation of the sun and moon, or upon the eccentricity, or the parallax, or the inclination of the lunar orbit. The inherent difficulties of this task were immensely enhanced by the fact that Euler was virtually blind, and had to carry all the elaborate computations it involved in his memory. A further difficulty arose from the burning of his house and the destruction of the greater part of his property in 1771. His manuscripts were fortunately preserved. His own life was only saved by the courage of a native of Basel, Peter Grimmon, who carried him out of the burning house.

Some time after this the celebrated Wenzell, by couching the cataract, restored Euler's sight; but a too harsh use of the recovered faculty, along with some carelessness on the part of the surgeons, brought about a relapse. With the assistance of his sons, and of Krafft and Lexell, however, he continued his labors, neither the loss of his sight nor the infirmities of an advanced age being sufficient to check his activity. Having engaged to furnish the Academy of St. Petersburg with as many memoirs as would be sufficient to complete its acts for twenty years after his death, he in seven years transmitted to the academy above seventy memoirs, and left above two hundred more, which were revised and completed by another hand.

Euler's knowledge was more general than might have been expected in one who had pursued with such unremitting ardor mathematics and astronomy as his favorite studies. He had made very considerable progress in medical, botanical, and chemical science, and he was an excellent classical scholar, and extensively read in general literature. He was much indebted to an uncommon memory, which seemed to retain every idea that was conveyed to it, either from reading or meditation. He could repeat the *Æneid* of Virgil from the beginning to the end without hesitation, and indicate the first and last line of every page of the edition which he used. Euler's constitution was uncommonly vigorous, and his general health was always good. He was enabled to continue his labors to the very close of his life, so that it was said of him that he ceased to calculate and to breathe at nearly the same moment. His last subject of investigation was the motion of balloons, and the last subject on which he conversed was the newly discovered planet Herschel. On the 18th September, 1783, whilst he was amusing himself at tea with one of his grandchildren, he was struck with apoplexy, which terminated his illustrious career at the age of seventy-six. Euler's genius was great, and his industry still greater. His works, if printed in their completeness, would occupy from 60 to 80 quarto volumes. He was simple and upright in his character, and had a strong religious faith. He was twice married, his second wife being a half-sister of his first, and he had a numerous family, several of whom attained to distinction. His *éloge* was written for the French Academy by Condorcet, and an account of his life, with a list of his works, was written by Von Fuss, the secretary to the Imperial Academy of St. Petersburg.

The works which Euler published separately are—*Dissertatio physica de Sono*, Basel, 1727, in 4to; *Mechanica, sive Motus scientia analytice exposita*, Petersb., 1736, in 2 vols. 4to; *Einleitung in die Arithmetik*, ibid. 1738, in 2 vols. 8vo, in German and Russian; *Tentamen Novæ Theoriæ Musicæ*, ibid. 1739, in 4to; *Methodus inveniendi lineas curvas, maximi minimive proprietate gaudentes*, Lausanne, 1744, in 4to; *Theoria motuum Planetarum et Cometarum*, Berlin, 1744, in 4to; *Beantwortung*, etc., or Answers to different Questions respecting Comets, ibid. 1744, in 8vo; *Neue Grundsätze*, etc., or New Principles of Artillery, translated from the English of Benjamin Robins, with notes and illustrations, ibid. 1745, in 8vo; *Opuscula varii argumenti*, ibid. 1746–51, in 3 vols. 4to; *Novæ et correctæ Tabulæ ad loca Lunæ computanda*, ibid. 1746, in 4to; *Tabulæ Astronomicæ Solis et Lunæ*, ibid. 4to; *Gedanken*, etc., or Thoughts on the Elements of Bodies, ibid. 4to; *Rettung der Gottlichen Offenbarung*, etc., Defence of Divine Revelation against Free-thinkers, ibid. 1747, in 4to; *Introductio in Analysin Infinitorum*, Lausanne, 1748, in 2 vols. 4to; *Scientia Navalis, seu Tractatus de construendis ac dirigendis navibus*, Petersb., 1749, in 2 vols. 4to; *Theoria motus Lunæ*, Berlin, 1753, in 4to; *Dissertatio de principio minimæ actionis, una cum examine Objectionum cl. prof. Kœnigii*, ibid. 1753, in 8vo; *Institutiones Calculi Differentialis, cum ejus usu in analysi Infinitorum ac doctrina Serierum*, ibid. 1755, in 4to; *Constructio Lentium Objectivarum*, etc., Petersb., 1762, in 4to; *Theoria motus corporum solidorum seu rigidorum*, Rostock, 1765, in 4to; *Institutiones Calculi Integralis*, Petersb., 1768–1770, in 3 vols. 4to; *Lettres à une Princesse d'Allemagne sur quelques sujets de Physique et Philosophie*, Petersb., 1768–1772, in 3 vols. 8vo; *Anleitung zur Algebra*, or Introduction to Algebra, ibid. 1770, in 8vo; *Dioptrica*, ibid. 1767–1771, in 3 vols 4to; *Theoria motuum Lunæ nova methodo pertractata*, ibid. 1772, in 4to; *Novæ Tabulæ Lunares*, ibid. in 8vo; *Théorie complète de la construction et de la manœuvre des Vaisseaux*, ibid. 1773, in 8vo; *Éclaircissements sur établissements en faveur tant des Veuves que des Morts*, without a date; *Opuscula Analytica*, Petersb., 1783–1785, in 2 vols. 4to.

EUMENES, a native of Cardia, a city in the Thracian Chersonesus, was born 360 B.C., and died in 315. At a very early age he was employed as private secretary by

Philip king of Macedonia, and on the death of that prince he was continued in the same office by Alexander. In this capacity he accompanied Alexander into Asia. The esteem in which he was held by his royal master was proved by his being retained in confidence in spite of the enmity of Hephæstion, by his appointment to a high military command, and by his marriage to Artonis, the daughter of Artabazus. Upon the death of Alexander, the provinces and armies were divided amongst his generals, and the countries assigned to Eumenes were Cappadocia and Paphlagonia, with the sea-coast of Pontus as far as Trapezus; but as they were not yet subdued, Leonnatus and Antigonus were charged by Perdiccas to put him in possession. Antigonus, however, disregarded the orders of Perdiccas; and Leonnatus, having in vain attempted to induce Eumenes to accompany him to the assistance of Antipater in Europe, made an unsuccessful attack on his life. Eumenes, however, escaped his vengeance and joined Perdiccas, who assisted him in taking possession of Cappadocia. When Craterus and Antipater, having reduced Greece, determined to pass into Asia and overthrow the power of Perdiccas, their first blow was aimed at Cappadocia; and in the emergency Eumenes was appointed commander of all the forces in the neighboring countries. But to this Neoptolemus, one of the generals, refused to submit; and being defeated by Eumenes, he fled to Antipater and Craterus. The presence of Antipater was required in Cilicia, and the army destined to act against Eumenes was therefore commanded by Craterus and Neoptolemus. They were, however, completely defeated; and Neoptolemus was killed, and Craterus died of his wounds, 321 B.C. When the Macedonian chiefs received intelligence of the defeat of two of their generals by one whom they considered a stranger, only a few days after the death of Perdiccas, they condemned Eumenes to death, and charged Antipater and Antigonus with the execution of their order. Eumenes was at first successful, but being defeated through the treachery of one of his officers, he fled to Nora, a strong fortress on the confines of Cappadocia and Lycaonia. Here he made a successful resistance, and was afterwards appointed by Olympias to command the army against Antigonus, whose intentions could no longer be misunderstood. He gained a battle against his adversary, but unfortunately lost the baggage and women belonging to his Macedonian phalanx. Antigonus offered to restore them on condition that the soldiers would surrender Eumenes into his hands. The offer was complied with, and Eumenes, having been thus basely betrayed, was put to death in the forty-fifth year of his age. (Plutarch, *Life of Eumenes;* Nepos; Diodor. Sic., xviii. 30.)

EUMENIDES. See ERINYES.

EUNAPIUS, a Greek sophist and historian, born at Sardis 347 A.D. In his native city he studied under his relative the sophist Chrysanthius, from whom it is supposed that he imbibed the enmity to Christianity which his works display. While still a youth he went to Athens, where he became a favorite pupil of Proæresius. He possessed a considerable knowledge of medicine. In his later years he seems to have resided at Athens, teaching rhetoric. There is evidence that he was still living in the reign of the younger Theodosius. He was the author of two works, one entitled *Lives of the Sophists* (*Βίοι φιλοσόφων καὶ σοφιστῶν*), and the other consisting of a continuation of the history of Dexippus. The former work is still extant, but of the latter only excerpts remain. The style of both works is bad, and they are written in a spirit of bitter hostility to Christianity. The *Lives of the Sophists*, which deals chiefly with the contemporaries of the author, is valuable as the only source for the history of the philosophy of that period. The best edition is that of Boissonade with notes by Wyttenbach (Amsterdam, 1822). See a notice of Eunapius by Cousin in his *Fragments philosophiques pour servir a l'histoire de la philosophie* (1865).

EUNOMIUS, one of the chief leaders of the extreme or Anomœan Arians, who are sometimes accordingly called Eunomians, was born at Dacora in Cappadocia early in the 4th century. Under the advice of the Arian bishop Secundus of Antioch, he was sent to Alexandria to study theology under Aetius, whose secretary he became. He afterwards came under the influence of Eudoxius of Antioch, where he was ordained deacon. On the recommendation of Eudoxius he was appointed bishop of Cyzicus in 360. In this position he gave unrestrained utterance to his extreme Arian views, with the result that the inhabitants of Cyzicus lodged a complaint against him, and Eudoxius was compelled, by command of the emperor Constantine, to depose him from the bishopric within a year of his elevation to it. During the reigns of Julian the Apostate and Jovian, he resided in Constantinople in close intercourse with Aetius, consolidating an heretical party and consecrating schismatical bishops. He next resided at Chalcedon, from which he was banished to Mauritania by the emperor Valens for harboring the rebel Procopius. He was recalled, however, before he reached his destination. In 383 the emperor Theodosius, who had demanded a declaration of faith from all party leaders, punished Eunomius for continuing to teach his distinctive doctrines, by banishing him to Halmyris in Mœsia. He afterwards resided at Chalcedon and at Cæsarea in Cappadocia, from which he was expelled by the inhabitants for writing against their bishop Basilius. His last days were spent at Dacora his birthplace, where he died about 394. The writings of Eunomius were held in high reputation by his party, and their influence was so much dreaded by the orthodox, that more than one imperial edict was issued for their destruction (*Cod. Theod.*, xvi. 34). Consequently his commentary on the epistle to the Romans, mentioned by the historian Socrates, and his epistles, mentioned by Philostorgius and Photius, are no longer extant. His first apologetical work ('Απολογητικός), written probably about 360 or 365, has been entirely recovered from the celebrated refutation of it by Basilius, and may be found in Fabricius's *Bibl. Gr.*, viii., pp. 262–305. A second apology, written before 379 (*ὑπὲρ ἀπολογίας ἀπολογία*), exists only in the quotations given from it in a refutation by Gregory of Nyssa. The exposition of faith (*Ἔκθεσις τῆς πίστεως*), called forth by the above-mentioned demand of Theodosius, is still extant, and has been edited by Valesius in his notes to Socrates, and by Rettberg in his *Marcelliana*. The doctrine of Eunomius, as displayed in these works, was developed by an exclusively logical application of the fundamental idea of the unity of God to the orthodox Trinitarian view. Denying alike the homoousian and the homoiousian theory, he was dialectically probably the ablest and most consistent defender of Anomœanism, or the doctrine according to which the Son is essentially or substantially different from the Father. According to Socrates (v. 24), Eunomius carried his doctrine to a practical issue by altering the baptismal formula. Instead of baptizing in the name of the Trinity, he baptized in the name of the Creator and into the death of Christ. This alteration was regarded by the orthodox as so serious that Eunomians on returning to the church were re-baptized, though the Arians were not. The Eunomian heresy was formally condemned by the œcumenical council of Constantinople. The sect maintained a separate existence for some time, but gradually fell away owing to internal divisions. It may be noted that Whiston's *Eunomianismus Redivivus* contains an English translation of the first apology of Eunomius.

EUNUCH (*εὐνοῦχος*), an emasculated person. From remote antiquity among the Orientals, as also at a later period in Greece, eunuchs were employed to take charge of the women, or generally as *chamberlains*,—whence the name, *οἱ τὴν εὐνὴν ἔχοντες*, *i.e.*, those who have charge of the bedchamber. Their position in the harems of princes affording them the ready means of access to the royal person, it is not surprising that they were frequently enabled to exercise an important influence over princes, and even to raise themselves to stations of great trust and power. Hence the term eunuch in Egypt came to be applied to any *court* officer, whether a castratus or not. The vulgar notion that eunuchs are necessarily deficient in courage and in intellectual vigor is amply refuted by history. We are told, for example, by Herodotus that in Persia they were especially prized for their fidelity; and they were frequently promoted to the highest offices. Narses, the famous general under Justinian, was a eunuch, as was also Hermias, governor of Atarnea in Mysia, to whose manes the great Aristotle offered sacrifices, besides celebrating the praises of his patron and friend in a poem (still extant), addressed to *Virtue* (see Lucian's dialogue entitled *Eunuchus*). To multiply instances were superfluous. The capacity of this class of persons for public affairs is strikingly illustrated by the histories of Persia, India, and China; and we need only allude to the power exercised by the eunuchs under the later Roman emperors. The hideous trade of castrating boys to be sold as eunuchs for Moslem harems has continued to modern times, the principal district whence they are taken being the inland of north-eastern Africa. As the larger proportion of children die after the operation (generally total removal), such as recover fetch at least three or four times the ordinary price of slaves. Even more vile, as being practised among a civilized European nation, has been the Italian practice of castrating boys to prevent the natural development of the voice, in order to train them as adult soprano singers, such as might till lately be heard in the Sixtine Chapel. Though such mutilation is a crime punishable with severity, the supply of "soprani" never failed so long as their musical powers were in demand in high quarters. Driven long ago from the Italian stage by public opinion, they remained the musical glory and moral shame of the papal choir till the accession of the present pope (Leo XIII.), one of whose first acts was to get rid of them. Mention must here also be made of the class of voluntary eunuchs, who have emasculated themselves, or caused the operation to be performed on them, for the avoidance of sexual sin or temptation. This unnatural development of asceticism appears in early Christian ages, its votaries acting on the texts Matt. xix. 12, v. 28–30. Origen's case is the most celebrated example, and by the 3d century there had arisen a sect of eunuchs, of whom Augustine says (*De Hœres.*, c. 37), "Valesii et seipsos castrant et hospites suos, hoc modo existimantes Deo se debere servire" (see Neander, *History of Chr. Church*, vol. ii. p. 462; Bingham, *Antiq. Chr. Church*, book iv. chap. 3). Such practices have been always opposed by the general body of the Christian churches, but have not even now ceased. It recently came into notice how large and prosperous a secret sect of the kind exists in Russia, whose practice of castration is expressed in the name of Skopzi, by which they are commonly described. (For details see F. v. Stein in *Zeitschrift für Ethnologie*, 1875, p. 37, and *Journal of Anthropology*, 1870; also Haxthausen, *Russian Empire*, vol. i.) (E. B. T.)

EUPATORIA, a seaport town of European Russia, at the head of a circle in the government of Taurida, about 50 miles N.W. of Simpheropol, on a sandy promonotory in the north of Kalamita Bay, in 45° 12′ N. lat. and 33° 5′ E. long. Of its numerous ecclesiastical buildings, which comprise 16 mosques, three synagogues, an Armenian, an Orthodox, and a Catholic church, only two are of special interest, the Karaite synagogue and one of the mosques, which has fourteen cupolas, and is built after the plan of St. Sophia in Constantinople. The shipping accommodation is poor, the port or rather roadstead having a sandy bottom, and being exposed to violent storms from the N.E. Small vessels cast anchor near the town in a depth of 18 or 15 feet. The trade is principally in grain, skins, cowhair, felt, tallow, and salt. In 1861, out of a population of 7081, 3422 were Mahometans, 1228 Karaite Jews, and 175 Talmudists. In 1871 the total was 8294.

It is believed that in the 5th century B.C. there was a town Coronitis in this part of the Chersonese, and according to some authorities it was near this spot that a military post called Eupatorium was established in the 1st century A.D. by Diophantes, the general of Mithradates Eupator. About the end of the 15th century the Tatars built the fortress of Gezlevé on the present site, and it became the centre of one of the principal towns of the Crimea. It was occupied for the first time by the Russians under Marshal Munich in 1736, and for the second time in 1771 by Prince Dolgorukoff. Its annexation to Russia took place in 1783, and in the following year it was made the chief town of a circle. In 1854 the Anglo-French troops were landed at Eupatoria, and in February, 1855, the town was occupied by the Turkish forces under Omar Pasha.

EUPEN (French *Néau*), the chief town of a circle in the district of Aix-la-Chapelle, Rhenish province of Prussia, is situated in a beautiful valley at the confluence of the Hill and Vesdre, on the Rhenish railway, 9 miles south of Aix-la-Chapelle. It is a flourishing commercial town, and besides cloth and buckskin mills, it has net and glove manufactories, soapworks, dyeworks, tanneries, and breweries, and also carries on a considerable trade in cattle, butter, and cheese. It has a Protestant and 6 Catholic churches, a Franciscan monastery, a town school of a high grade, an orphanage, a hospital, an infirmary, and a lunatic asylum. Eupen until 1801 was under the government of Austria, and belonged to the duchy of Limburg, but at the peace of Lunéville it came into the possession of France, and in 1814 into that of Prussia. The population in 1875 was 14,895.

EUPHORBIUM, an acrid dull-yellow or brown resin, consisting of the concreted milky juice of *Euphorbia resinifera*, Berg., a cactus-like perennial plant of the natural order Euphorbiaceæ, indigenous to Morocco. It is procured by making incisions in the branches of the plant, and allowing the juice to harden in the heat of the sun. In collecting it, the protection of the mouth and nostrils by a cloth is requisite, as the dust occasions violent sneezing if inhaled. Euphorbium has a taste at first little marked, but afterwards hot and acrid. It dissolves in alcohol, ether, and turpentine; in water it is only slightly soluble. Its constituents, according to Flückiger, are 38 per cent. of an amorphous resin, to which the drug owes its acridity, and 22 per cent. of *euphorbon*,—together with mucilage, malates, and mineral compounds. Pliny states that the name of the drug was given to it in honor of Euphorbus, the physician of Juba II., king of Mauritania. In former times euphorbium was valued in medicine for its drastic, purgative, and emetic properties; and as an errhine it is still occasionally resorted to. On account of the violence of its action, it requires to be mixed for use with starch or flour. As a vesicant it has been employed as a substitute for cantharides in veterinary practice.

See Flückiger and Hanbury, *Pharmacographia*, 1874; Bentley and Trimen, *Medical Plants*, tab. 240.

EUPHORION, a Greek poet and grammarian, was the son of Polymnetus, and was born at Chalcis in Eubœa in the 126th Olympiad, 274 B.C. He studied philosophy under Lacydes and Prytanis, and poetry under Archebulus the Therean. After amassing great wealth, he retired (221 B.C.) to the court of Syria, and there assisted Antiochus the Great in forming the royal library at Antioch, which it was intended should rival that of Alexandria; and in this employment he died probably about 200 B.C. His poetry was principally epic, but he was also an epigrammatist, and has besides been supposed, though without sufficient reason, to have written dramas. Only a few fragments of his works have been preserved; but from the opinions expressed by ancient writers, it appears that he was constantly in search of archaic and obsolete expressions, and that the erudite character of his allusions rendered him so obscure as to be understood with difficulty. His works appear to have been popular as late as the times of the emperor Tiberius.

The fragments have been edited by Meineke under the title *De Euphorionis Chalcidensis Vita et Scriptis*, etc., Dantzic, 1823. This work with amendments has been published by Meineke in his *Analecta Alexandrina*, Berlin, 1843. See also Clinton's *Fasti Hellenici*, vol. ii. p. 511; Fabricius, *Bib. Græc.*, vol. i. p. 594; Heyne, *De Euphorione*, *Excurs.* iii. *ad Virg. Bucol.* and *Excurs.* v. *ad Æn.* ii.

EUPHRANOR, a painter and statuary of Greece, who flourished about the middle of the 4th century B.C., was born in the territory of Corinth, but, having practised his art and acquired his renown at Athens, is always identified with the Athenian school. In sculpture he produced a great number of pieces, from colossal life-figures to drinking cups. Of the finest of these, a figure of Paris, a beautiful copy now exists in the Museo Pio-Clementino in the Vatican. His principal pictorial work was extant in the time of Pausanias in one of the porches of the Ceramicus. It represented on one side of the wall the twelve gods, and on the other Theseus as the founder of the equal polity of Athens. Among the pupils of Euphranor were Antidotus, Carmanides, and Leonidus of Anthedon. He was the author of some works on color and proportion, which seem to have been the characteristic excellences of his own pieces.

EUPHRATES. The Euphrates has been one of the best known rivers of the world from the remotest antiquity. It may be considered, roughly speaking, as divided into three portions, the upper, middle, and lower divisions, each of which is distinguished by special physical features, and each of which has played a conspicuous part in the world's history, retaining to the present day monumental evidence of the races who have lined its banks. The upper division is formed of two arms, called respectively the Frát[1] and the Murád (different forms in all probability of the same name), which rise, the one a short distance to the N.E. of Erzeroum, and the other to the N.W. of Lake Van near Diyadín, and which unite in the vicinity of Keban Maaden, about 39° N. lat. and 39° E. long. on the high road conducting from Sivas to Diarbekir. This upper division of the river bisects the plateau of Asia Minor, and has thus been traversed by all the nations who have passed successively from Asia into eastern Europe. It still exhibits at Paloo, at Malatíeh, and in some other places, on the precipitous rocks which form its banks, cuneiform inscriptions of the Scytho-Arian dynasty, which ruled in Armenia in the 8th century B.C. Here the general character of the Euphrates is that of a river of the first order struggling through high hills or rather low mountains, prolongations of the chain of Anti-Taurus, and making an exceedingly tortuous course as it forces its way over a rocky or a pebbly bed from one natural barrier to another. As it winds round its numerous barriers it carries occasionally towards each of the cardinal points a considerable body of water and is shallow enough in some places for loaded camels to pass in autumn, the water rising to about 4½ feet. The general direction of the left arm of the Euphrates, which is termed the Murád-chäí, and which, rising near Diyadín, skirts the plains both of Músh and Kharpút, is westerly as far as its junction with the right arm near Keban Maaden. This right arm again, which rises near Erzeroum, and which, though of inferior length and size, is generally regarded as the true Euphrates, runs south-westerly by Erzingán Kamakh (*Kumukh* of the inscriptions, and Gr. *Κομμαγηνή*) and Egin to the point of junction. There, however, the direction of the river changes. Meeting obliquely the Anti-Taurus, which afterwards rises into the Jújik-dagh (the Mount Abus of antiquity), it is forced to the south through some very precipitous gorges to the vicinity of Malatíeh. It then crosses the broken country between the Anti-Taurus and Taurus, and finally forces its way through the latter range in a succession of rapids and cataracts for a space of about 40 miles, till it emerges upon the great Syrian plain, a short distance above Samsát, the ancient Samosata, where Lucian dwelt and wrote. The Euphrates now enters on its middle division, which may be considered to extend from Samsát to Hít. The direction here is at first S.W., then S., and afterwards S.E. from about the 36th parallel of latitude to its embouchure in the Persian Gulf. The river in this part of its course runs through a valley of a few miles in width, which it has eroded in the rocky surface, and which, being more or less covered with alluvial soil, is pretty generally cultivated by artificial irrigation. The method of irrigation is peculiar, dams of solid masonry being run into the bed of the river, frequently from both sides at once, so as to raise the level of the stream and thus to give a water power of several feet in height which is used to turn a gigantic wheel sometimes 40 feet in diameter. The water is thus raised to a trough at the top of the dam, and from thence is distributed among the gardens, and melon beds, and rice fields, occupying the valley between the immediate bed of the river and the rocky banks which shut it out from the desert. The wheels, which are of the most primitive construction, being made of rough branches of trees, with 100 or 150 rude clay vessels slung on the outer edge, raise a prodigious amount of water, and are moreover exceedingly picturesque, the dams or aqueducts to which they are attached being often formed of a series of well-built Gothic arches; but they are great impediments to navigation, as they cause a current of six or seven knots an hour, which cannot be surmounted by any ordinary steam power. In some parts of the river 300 of these wheels have been counted within a space of 130 miles, and when our steamers first appeared upon the river, not forty years ago, at least one-third of the wheels were in working order; but they have since fallen very generally into ruin, the Arab population, which used to cultivate the immediate banks of the river, having for the most part moved further off into the desert. The rocks which form the river banks during this part of its course are composed of gypsum, sandstone, and conglomerate with mica and felspar, and at some points, as at Helebí-Jelebí (the Zabá and Zalá of the Arabs) approach close to the water's edge. Beyond the rocky banks on both sides is the open desert, covered in spring with a luxuriant verdure, and dotted here and there with the black tent of the Bedouín, the great tribe of Shamar holding the left bank or Jezíréh, as the 'Anezeh possess the right bank or Shámíyeh. The middle course of the Euphrates has also played a great part in history. In very early times it formed a boundary between the empire of Assyria to the east and the great nation of the Khetta, or Hittites, to the west; and the capital of the latter people, known in Scripture as Carchemish (2 Chron. xxxv. 20), was built upon its banks. The ruins of this city, now known as Yerábolus, a corruption of the Greek Hierapolis, have been recently examined by Mr. George Smith, and are found to contain numerous well-preserved bas-reliefs (with inscriptions in the Hamathite character), which promise to be of the utmost importance as forming the connecting link that has been long sought between Egyptian and Assyrian art. In the vicinity of Hierapolis, or Carchemish, was the upper passage of the Euphrates on the road conducting from Syria to Nineveh. The site is now known as Bir or Birejek, but it retained the title of Zugma (Greek, *ζεῦγμα*), according to the Arab geographers, to comparatively modern times (see Yacút in voce), and the remains of the old bridge were still to be seen there in the 7th century of the Hegira, popularly known as the *Jisr Membij*, or bridge of Membij, the Arabic form of the Syriac Mabog or Hierapolis. The lower passage of the Euphrates conducting from Syria to Babylonia, which retained, among the Greeks, the old Semitic title of Thapsacus (or תפסח, 1 Kings v. 4, etc.), is usually placed at Der, 200 miles lower down the river; but Captain Lynch, who carefully examined the country, would prefer the position of *Phunsah* above Racca, where he found the remains of an ancient bridge. The Euphrates is singularly deficient in tributaries after it leaves the mountains; with the exception, indeed, of the *Sanjeh* (*Σίγγας* of the Greeks) and the *Sajur* (Sangar of the Assyrian inscriptions) on the right bank, and the *Bilikh* and *Khabúr* on the left, which have retained their present names unchanged for thirty centuries, there is no affluent to the Euphrates of any consequence after it has once broken through the Taurus range. In antiquity, indeed, there would seem to have been a river named Araxes by Xenophon, and Saocoras by Ptolemy, which descended from the Sinjar hills, and, running due south, joined the Euphrates between Der and Annah; but no traces of such a stream are now to be found, and it has been suggested therefore that its disappearance may be due to the same upheaval of the land at the south-eastern foot of the Sinjar hills, which diverted the Nisibín river (Gozan of Scripture, Mygdonius of the Greeks, and Hermas of the Arabs) from its ancient course by Hatra to Tekrit on the Tigris, and forced it to join the Khabúr and ultimately the Euphrates.

---

[1] The original name of the Euphrates, *Burat* or *Purat*, represents probably a very old Asiatic root, *Bur* or *Pur* (corresponding with the Welsh *Bwrw* and English "pour"), with a Semitic feminine ending. The full form of *Hufrat*, whence the Gr. Εὐφράτης, is first found in the inscriptions of Darius Hystaspes, the initial syllable having been

During the Mahometan period there were many flourishing towns on the banks of the river in the middle part of its course. The geographers mention in succession Someisát, Rúm-Kaleh, Jisr-Mambej or Bír, Beles, El Ja'aber (or Dusar), Racca (Nicephorium at the mouth of the Bilikh), Kerkessíeh (Circessium at the mouth of the Khabúr), Rahbeh, Dér-el-Káim (Gordian's tomb? and the boundary between the Roman and Persian empires), Annah (or Anatho), Haditheh, Alús, Náúseh, and Hít. Many of these cities are now in ruins, but the sites can for the most part be identified, and they would all well repay a careful examination; at present the most considerable towns are Samsát, Bír, Annah, and Hít. From Bír to Ja'aber the river is rather sluggish, running over a sandy or pebbly bed; further down, and as far as Hít, the general character of the bed is rocky, and between Annah and Hít, it is thickly studded with islands, on which were built in former times the castles and treasuries of the rulers of the land, many of these islands being still inhabited.

Hít,[1] which may be fixed on as the point of demarcation between the middle and lower divisions of the river, stands at the head of the alluvial deposit. It is distant about 750

---

prefixed apparently by the Persians, in order to obtain a suitable Arian etymology for the name *Hufrat*, signifying "the good abounding." The fluvial root *Bur* is perhaps to be recognized in Borysthenes, Kha-bur, and some other names.

[1] The true name of this place seems to have been *Ihi*, which is often found in the Talmud in the compound form of *Ihi-da-kira*, or "*Ihi* of the Bitumen," from the famous bituminous springs in the vicinity. Herodotus wrote the name as Ἶς, with the Greek nominatival ending, while in *Hít* we have the Arabic feminine suffix. Isidore gives the form of Αείπολις; Ptolemy has Ἰδικάρα, Ammianus Diacira, and Zosimus Δάκιρα,—the last three forms all referring to the bitumen springs. The name has not been recognized in the Assyrian inscriptions, though it is curious to observe that in Proto-Babylonian "Bitumen" was named *Ittu*, a form very much resembling the modern *Hít*.

miles by the windings of the river from the point where the Euphrates breaks through the Taurus range, and the further course of the stream measures about 550 miles to the sea. The hills and cliffs and rocky banks which have hitherto lined the river disappear, and, with the exception of one limited tract a short distance above Babylon, named El Haswa, there is not a stone or a pebble to be seen on the surface of the desert all the way to the sea. In the immediate vicinity of Hít a large canal was taken off on the right bank of the river, which followed the extreme skirt of the alluvium the whole way to the Persian Gulf, and thus formed an outer barrier, strengthened at intervals with watch-towers and fortified posts, to protect the cultivated land of the Sowád against the incursions of the desert Arabs. This gigantic work, the line of which is still to be traced throughout its course, was formerly called the *Khandak-Sabúr*, or "Sapor's trench," being historically ascribed to the Sassanian king, Shapúr Dhulaktáf, but it is known in the country as the Cherra-Saídeh, and is in popular tradition believed to have been excavated by Bokhtunasr (Nebuchadnezzar) for his favorite "sultáneh," Saídeh, "the fortunate." The great irrigating canals, however, which especially distinguished Babylonia, were derived from the left bank of the river, and watered the country between the Euphrates and the Tigris. Many of them must have been of the most remote antiquity, as the majority of the primitive capitals—such as Kuthá, and Niffer, and Larsa, etc., sister cities of Babylon—were built upon their banks, and are thus proved to be of a later date than the canals. In the time of the Arabs the chief canals were the Nahr Isá, the Nahr Sarsar, the Nahr Malcá (the royal river of the Greeks), and the Nahr Kuthá, and the cuts from these main channels, reticulating the entire country between the rivers, converted it into a continuous and luxuriant garden. The most important canal, however, was the large stream which left the Babylonian branch of the Euphrates just above the city, and under the name of the *Arakhat*[1] (Archous of the Greeks and *Serrát* and *Níl* of the Arabs) ran due east to the Tigris, irrigating all the central part of the Jezíreh, and sending down a branch as far south as Niffer. At the present day it is easy to distinguish these great primitive water courses from the lateral ducts which they fed, the former being almost without banks, and merely traceable by the winding curves of the layers of alluvium in the bed, while the latter are hedged in by high banks of mud, heaped up during centuries of dredging. Not a hundredth part of the old irrigation system is now in working order. A few of the mouths of the smaller canals are kept open so as to receive a limited supply of water at the rise of the river in May, which then distributes itself over the lower lying lands in the interior, almost without labor on the part of the cultivators, giving birth in such localities to the most abundant crops; but by far the larger portion of the region between the rivers is at present an arid, howling wilderness, strewed in the most part with broken pottery, the evidence of former habitation, and bearing nothing but the camel thorn, the wild caper, the colocynth-apple, wormwood, and the other weeds of the desert. It must further be borne in mind that the course of the river and the features of the country on both banks are subject to constant fluctuation. Between Hít, it is true, and Felugia (near the ancient Perisabor, *Anbár* of the Arabs) which is at the head of the canal system, no great change is possible owing to the height of the river banks, but lower down everything depends on the care bestowed on the artificial embankments of the stream. When the Euphrates, for instance, breaks through at Felugia, and fills the Saklawíeh canal (in the line of the old *Nahr 'Isá*) the whole country west of Baghdad is submerged, and a still more important flooding occurs lower down near Mussáib, at the head of the modern Hindíeh canal. Here in all ages there has been a great bifurcation of the river. We may infer that the right arm was the original bed, and the left arm, on which Babylon was built, the artificial derivation, because from the earliest times, as we learn from the cuneiform inscriptions, the Babylon stream has always been called the river of Sippara and not the Euphrates. In the time of Alexander, it is true, the nomenclature had been reversed, the right arm being then known as the Pallacopas, which means an artificial canal;[2] but under the Arabs and until comparatively modern times, the old distribution has again prevailed, the Euphrates being always described in history as the river which flowed direct to Kúfa (near the modern Nejef, the tomb of Ali), while the present stream, passing along the ruins of Babylon to Hillah and Diwaníeh, has been universally known as the Nahr *Surá*, a mere corruption of the ancient title of Sippara.[3] At the present day the preservation of the embankments at the point of bifurcation demands the constant care of the Baghdad Government. The object is to allow sufficient water to drain off to the westward for the due irrigation of the lands cultivated by the Khezzáil Arabs below Nejef, while the Hillah bed still retains the main volume of the stream, and is navigable to the sea; but it frequently happens that the dams at the head of the Hindíeh are carried away, and that a free channel being thus opened for the waters of the river to the westward, the Hillah bed shoals to 2 or 3 feet, and is everywhere fordable. But whether the main body of the stream may flow in the right arm or in the left, the lower portion of the Euphrates—that is, a tract of 200 miles in length intervening between Diwaníeh and the junction of the two great rivers at Korna,—forms and has always formed a succession of reedy lagoons of the most hopeless character. These were the Paludes Chaldaici of antiquity, the *El Batihát* of the Arabs, and they are best known to us at present as the Lemlún marshes, though that name is by no means of general application. It may be doubted if the fall of the land will ever admit of these marshes being drained, and certainly in its present condition a more unproductive and unpromising tract of country than the lake region can hardly be conceived. The navigation through the long lines of reeds is subject to constant interruption, the climate is pestilential, the inhabitants wild and inhospitable, and yet there are many mounds and ancient sites among the marshes that would well repay excavation, dating as they do from the earliest Chaldean times. The antiquities indeed, of the lower Euphrates are all of the highest interest, for here were established the earliest seats of civilization, and here accordingly were localized the traditions of a terrestrial paradise. Erech (modern Warka) and "Ur of the Chaldees" (now Mugheir) were both in the immediate vicinity of the river, the banks of which, below the junction of the Samáwá branch, the outpour of the Hindíeh waters, everywhere bear evidence of a teeming population in ancient times. From Korna, where the Tigris and Euphrates at present unite, the river sweeps on in its majestic course to Bussorah; it is here 1000 yards in width, and from 3 to 5 fathoms deep, so as to be navigable by vessels of war, which not unfrequently ascend as far as the junction. Bussorah, which was formerly a very considerable city, but has now dwindled to a small town of 10,000 inhabitants, lies in a creek at the distance of a couple of miles from the river. Off the mouth of the creek, however, the Euphrates usually presents a somewhat animated appearance, the headquarters of the Turkish naval force in the Persian Gulf being here established, and several mercantile steamers from Bombay and Baghdad being also not unfrequently anchored in the roads. The native craft is likewise numerous, and occasionally the port is visited by a vessel of war from the British squadron in the gulf. From Korna to Bussorah the banks of the river are well cultivated, and the date groves are almost continuous. Twenty-five miles further down the river Karún from Shuster and Dizful throws off an arm, which seems to be artificial, into the Euphrates. This arm is named the Haffár, and at the confluence is situated the Persian town of Mohamrah, a place which is most conveniently placed for trade, and which in the future is likely to become a place of much consequence. In the vicinity of Mohamrah was situated, at the time of the Christian era, the Parthian city of Spasini-Charax, which was succeeded by *Bahman Ardeshir* (now Bamishír) under the Sassanians, and by *Moharzi* under the Arabs. The left bank of the river from this point belongs to Persia. It consists of an island named Abadán, about 45 miles in length, which has been formed by the alluvial deposits brought down by the river during the last fifteen centuries. New land, indeed, is yearly rising at the mouth of the river; and Fao, where we have established our telegraphic terminus connecting the Bombay and Constantinople wires, although at present on the seashore, is not likely long to remain so. The entire length of the Euphrates from its source near Diadín to Fao cannot be less than 1600 miles, and for three-quarters of that distance, or as far as Bír, it is more or less navigable by light boats and rafts.

---

[1] The Assyrian *Arakhat* means "the road," and is thus precisely synonymous with the Arabic *Serrát*, while the Bedouín of the present day apply to different portions of this canal the names of *Derb* and *Súk*, with the same meaning. At the time of the Arab conquest the name of *Serrât-el-Jamasb* was that chiefly in use, but in later times the upper and lower divisions of the canal were more often called "the two Zabs," after the famous river of that name in Assyria.

[2] The first element of this compound may be compared with the Hebrew פּלג, "division," a root which has also produced the Arabic name of *Pelugia;* and in the second element we may perhaps recognize the גוף or *Jouf*, which was the name given to the natural depression now filled by the "sea of Nejef."

[3] The two Sipparas represented in the Bible by the dual form of Sepharvaim, were situated on the Euphrates near the point of bifurcation, but the exact spot cannot now be recognized, owing to the frequent destruction and re-formation of the banks of the river in this part of its course. Under the form of *Surán* or *Surá*, the place became famous in the Middle Ages as the site of a great Jewish academy, while the bridge by which the river was crossed on the high road from Baghdad to Kúfa was also known as the *Jisr-Surá*. The name still appertains to some remains, of no great mark or extent, immediately above the site of Babylon, but the old city of Sippara was probably higher up the river, and not far from the modern town of *Mufsáib*.

Euphrates valley. The Euphrates valley, independently of its great natural advantages, has attracted some attention in recent times from its geographical position, forming as it does the most direct line of transit between the Mediterranean and the Persian Gulf, and thus offering an alternative means of communication with India, not greatly inferior to the route through Egypt. During our wars with Napoleon, early in the present century, and indeed up to the time when the introduction of steam navigation rendered the Red Sea accessible at all seasons of the year, the political correspondence of the home and Indian Governments usually passed by what is called "the Euphrates route," swift dromedaries conveying the mails across the desert from Bussorah to Aleppo on one line, while Tartars on post horses on the other rode from Baghdad direct to Constantinople; and even to the present day these postal lines are kept up with some modifications for the conveyance of correspondence between Baghdad and Europe. The greater facilities and the greater expedition of the Egyptian route,—especially since the construction of railways from Alexandria to Suez, and yet more recently the opening of the Suez Canal,—have, it must be allowed, established that line in popular estimation as the high road to India, but still not entirely to the exclusion of the Euphrates valley route. Various plans, indeed, have been suggested and partly executed at different times, with a view to opening up communication between the Mediterranean and the Persian Gulf. The British Government commenced in 1835 by sending out Colonel Chesney at the head of an expedition to Syria, with instructions to transport two steamers from the Mediterranean to the Euphrates, and after putting them together at Bír, N.E. of Aleppo, to attempt the descent of the river to the sea. One of these steamers was lost in a squall during the passage down the river, but the other performed the voyage in safety, and thus demonstrated the practicability of the downward navigation. Following on this first experiment, the East India Company, in 1841, proposed to maintain a permanent flotilla on the Tigris and Euphrates, and sent two vessels accordingly, the "Nitocris" and the "Nimrod," under the command of Captain Campbell of the Indian Navy, to attempt the ascent of the latter river. The experiment was so far successful that, with incredible difficulty, the two vessels did actually reach Beles, about the same parallel as Aleppo, but the result of the expedition was to show that practically the river could not be used as a high road of commerce, the continuous rapids and falls during the low season, caused mainly by the artificial obstructions of the irrigating dams, being insurmountable by ordinary steam power, and the aid of hundreds of hands being thus required to drag the vessels up the stream at those points by main force; and all subsequent experience has confirmed this view, so that at the present day, although many of the dams have been cleared away, and the navigation of the river has been generally much improved, the Turkish authorities do not attempt to run their steamers up and down throughout the year, but content themselves with a few trips between Beles and Hillah, while the river remains in flood from April to August, with the political object of controlling the riverain tribes rather than for purposes of commerce. The unsuitability of the Euphrates for continuous steam navigation was no sooner clearly ascertained than public attention began to be directed to a communication between the Mediterranean and the Persian Gulf by rail, and from that time to the present, under a hundred different forms, the Euphrates valley railway has been under the consideration both of the political and the commercial world. In the year 1872 a select committee of the House of Commons reported generally in favor of the line, remarking that about £10,000,000 sterling would probably be sufficient to cover the expense of a railway along the shortest route between the seas; and adding that the principal advantages to be derived from such an expenditure would be:—1st, the more rapid transmission of the mails between England and India; 2d, the possession of an alternative and more rapid route for the conveyance of troops; and 3d, the great extension of commerce which would follow from the opening up of such a line of communication between India and England. How the money was to be obtained, however, the committee did not venture to recommend. They merely suggested that the English Government should enter into communication with the Turkish Government, with a view to some arrangement for a joint responsibility in raising the necessary funds, and it was on this money question that the whole scheme, and a great number of similar private schemes, fell through. It is pretty certain, indeed, that a railway of 1000 or 1200 miles through the Syrian and Mesopotamian deserts, dependent for its support entirely on the termini upon the two seas, can never be pecuniarily remunerative; and so long, therefore, as the British Government retains its hold on the Egyptian line it can hardly be worth its while to embark on so costly an undertaking merely for its possible political advantages. If the Sublime Porte had retained its position in the political world, it might have been a sound and proper measure of domestic economy to have laid down a railway from the Mediterranean to the Persian Gulf, with a view to developing the resources of the intermediate countries, and consolidating the power of the central government. Midhat Pasha, indeed, the author of the Turkish constitution, had thus some years ago, when he was governor of Baghdad, actually completed the preliminary surveys for a line from Tripoli on the Mediterranean, across the desert to Tekrit on the Tigris, and thence by Baghdad to Bussorah; and if he had remained in office the project would have been probably executed; but under present circumstances, when Asiatic Turkey threatens to become yearly more hopelessly disorganized, there is no reasonable prospect of such a scheme being resumed under native auspices. It is only, indeed, in the possible event of the Tigris and Euphrates valleys falling into the hands of a European power that we can look with any hope to the construction of railways, or the scientific embankment of the rivers, or the excavation of canals, or any of those measures of internal improvement which, however, if executed with care and skill, would soon restore these now desolate regions to their former exceptional condition of populousness, wealth, and general prosperity.

It may be of interest to add that the India Office has recently employed Captain Felix Jones, an accomplished officer of the late Indian navy, and one of the most experienced surveyors of that noble service, in constructing a map of the Euphrates and Tigris upon a large scale. All the charts and plans executed by Col. Chesney, Capt. H. B. Lynch, and the various officers of the Indian navy who have been employed during the last 40 years on the survey of Mesopotamia, and most of whose memoirs have been published in the current volumes of the Royal Geographical Society's Journal, have been utilized for the purpose, and the result has been the production of a map not less remarkable as a specimen of the highest cartographic skill than for its general scientific accuracy and its unusual fulness of detail. It is to be hoped that this map will be soon engraved, and thus rendered generally accessible to the public. (H. C. R.)

EUPION (Greek, εὖ, well, πίων, fat), a hydrocarbon of the paraffin series, discovered by Reichenbach in wood-tar. It is a colorless and highly volatile and inflammable liquid, having at 20° C. a specific gravity of 0.65, and expanding considerably when heated. It is unaffected by alkalies and mineral acids, and unites directly with the haloid elements. Eupion is formed in the destructive distillation of many substances, as wood, coal, caoutchouc, bones, resin, and the fixed oils. It is most conveniently prepared from rectified bone oil and rape and hemp seed oils, by treatment with sulphuric acid. Like other liquids of similar composition, it is employed for illuminating purposes, and, mixed with rape and cotton-seed oils, for the lubrication of machinery.

EUPOLIS, an Athenian poet of the Old Comedy, and, in the judgment of Horace, ranking along with Cratinus and Aristophanes as the greatest of that school, was the son of Sosipolis, and was born 445 B.C. Nothing whatever is known of his personal history. With regard to his death, he is said to have been thrown into the sea by Alcibiades, who had suffered from his attacks in the Βάπται. Cicero, however, points out that Eratosthenes mentions plays produced by Eupolis after the Sicilian expedition in which Alcibiades is said to have taken this revenge. It is much more likely, therefore, and much more generally believed, that he fell at the battle either of Cynossema, 411 B.C., or of Ægospotami, 408 B.C. To a lively and fertile fancy Eupolis added a sound practical judgment, which prompted him to a thorough mastery of the mechanical part of his art. The result of his studies was that he was reputed to equal Aristophanes in the elegance and purity of his diction, and Cratinus in the command of the most bitter irony and pungent sarcasm. Very curious and complicated relations subsisted between Eupolis and Aristophanes, who accused each other with the bitterest virulence, not only of imitation but of plagiarism. Some of these attacks will be found described in various parts of the scholia upon Aristophanes. The plays of Eupolis are said to have numbered in all seventeen. Meineke gives the names of fifteen which he considers genuine, and an analysis of those whose subjects can be decided from the surviving fragments.

EUPOMPUS, one of the most celebrated of Greek painters, was a native of Sicyon, and a contemporary of Zeuxis and Parrhasius, who flourished in the 4th century B.C. He was the head of the Sicyonian school of art, and was held in very high esteem by his countrymen. When Lysippus the sculptor was beginning his career, he consulted Eupompus as to whom he should take for his model. "Take Nature herself for your model," replied Eupompus, "and be not shackled by the trammels of any predecessor." No mention is made of more than a single piece by Eupompus —a victor in the games bearing a palm.

EURE, a department in the north-east of France, one of the five formed out of the old province of Normandy, is bounded on the N. by the department of Seine Inférieure, W. by Calvados, S. by Orne and Eure-et-Loir, and E. by Seine-et-Oise and Oise. It has an area of 2420 square miles, and lies between 48° 39′ and 49° 29′ N. lat., and 0° 15′ and 1° 45′ E. long. The surface is flat, with some ranges of low hills, none of them exceeding 300 feet in height. The Seine flows from S.E. to N.W. through the department dividing it into two unequal parts, and after touching the frontier at two or three points forms near its mouth part of the northern boundary. All the rivers of the department flow into the Seine,—on the right bank the Audelle and the Epte, and on the left the Eure with its tributaries the Avre and the Iton, and the Rille with its tributary the Charentonne. The Eure, from which the department takes its name, rises in Orne, and flowing first east and then west through Eure-et-Loir, falls into the Seine 6 miles below Louviers, after a course of 93 miles. The Rille likewise rises in Orne, and flows generally northward to its mouth in the estuary of the Seine. The climate is mild, but moist and variable. The soil is generally clayey, resting on a bed of chalk; but along the Seine there are some barren sandy tracts quite incapable of cultivation. A great part of the department, however, is very fertile and well tilled. The chief cereal cultivated is wheat, but flax also is largely grown. There is a wide extent of pasturage on which are reared a considerable number of cattle and sheep, and especially those horses of pure Norman breed for which the department has long been celebrated. Fruit is very abundant, especially apples and pears, from which much cider and perry are made, and vineyards on the Seine, Eure, and Avre yield a considerable quantity of wine. Wild game, especially of the winged sorts, is very plentiful, and the rivers abound in fish. Iron ore is very abundant, and the department is noted for its mining and manufacturing industry. Cotton, linen, and woollen cloths of every kind are fabricated. There are large establishments for making copper ware of all kinds, the various descriptions of paper, nails, pins, and needles, glass for windows and glass bottles, and jewelry and trinkets. Such goods form the trade; and, in addition to these, firewood, timber, cattle, honey, wax, and corn are furnished to the district surrounding the department. Eure is divided into the following arrondissements:—Evreux, Louviers, Les Andelys, Bernay, and Pont-Audemer; and its capital is Evreux. Notwithstanding the number of industries carried on in the department, the population has for some time been decreasing; while in 1851 it was 415,777, it was only 377,874 in 1872, and 373,629 in 1876.

EURE-ET-LOIR, a department in the northern part of France, formed out of portions of Orléanais, Maine, and Isle-de-France, is bounded on the N. by the department of Eure, W. by Orne and Sarthe, S. by Loir-et-Cher, S.E. by Loiret, and N.E. by Seine-et-Oise. It has an area of 2361 square miles, and lies between 47° 57′ and 48° 57′ N. lat., and 0° 44′ and 2° 0′ E. long. The western and north-western parts consist of undulations of hill and valley, with springs, rivulets, and small lakes. The eastern part is a level and uniform and very fruitful plain. The northern part is watered by the Eure, with its tributaries the Vègre, Blaise, and Avre, a small western portion by the Huisne, and the southern by the Loir with its tributaries the Connie and the Ozanne. The air is pure, and the climate mild, and not subject to sudden changes. The soil consists, for the most part, either of clay intermixed with sand or of calcareous earth, and is on the whole fruitful; but in some portions of the S.W. it is sandy and dry, and many tracts of land are so poor as to be uncultivated. The agriculture is better conducted than in most of the departments of France, and the average yield of the various kinds of corn is about three times greater. The wheat is remarkably fine; and among the other agricultural products are rye, barley, oats, hemp, flax, beet-root, melons, and onions. Wine is not extensively produced, nor of the best quality; but in some parts there is an abundant supply of apples, from which cider is made as the common drink of the inhabitants. The extensive meadows supply pasturage for a large number of cattle and sheep, the average yield of wool being double that of any of the other departments. There are some iron mines, and granite, marble, and gypsum quarries. The manufactures are not extensive; but leather, paper, cotton goods of various kinds, serges, flannels, and other coarse woollens, hosiery, hats, caps, household linen (such as sheetings and table linen), and some earthenware are furnished. The department has Chartres for its capital, and is divided into the arrondissements of Chartres, Châteaudun, Dreux, and Nogent-le-Rotrou. The population, which in 1851 was 415,777, was 282,622 in 1872 and 283,075 in 1876.

EURIPIDES is the mediator between ancient and modern drama. No great poet is more difficult to estimate justly, and none has been judged more unfairly. He cannot claim the full excellence of the school from which he began the departure, nor yet that of the school which at last arose on the foundations laid by him. His time forced an inner conflict on the art to which his genius was devoted. We must try not to look at him either wholly from a modern stand-point, or wholly from that of the age which he closed, but rather to place ourselves, as far as we can, at the line of separation on which he stood, and endeavor to see how he dealt with the perplexing forces of an inevitable transition.

Life 480–406 B.C.

All that is known about his outward life may be shortly told. He was born in 480 B.C., on the very day, according to the legend, of the Greek victory at Salamis, where his Athenian parents had taken refuge; and a whimsical fancy has even suggested that his name—*son of Euripus*—was meant to commemorate the first check of the Persian fleet at Artemisium. His father, Mnesarchus was at least able to give him a liberal education; it was a favorite taunt with the comic poets that his mother Clito had been an herb-seller—a quaint instance of the tone which public satire could then adopt with plausible effect. At first he was intended, we are told, for the profession of an athlete—a calling of which he has recorded his opinion with something like the courage of Xenophanes. He seems also to have essayed painting; but at five-and-twenty he brought out his first play, the *Peliades*, and thenceforth he was a tragic poet. At thirty-nine he gained the first prize, and in his career of about fifty years he gained it only five times in all. This fact is perfectly consistent with his unquestionably great and growing popularity in his own day. Throughout life he had to compete with Sophocles, and with other poets who represented tragedy of the type consecrated by a splendid tradition. It was but natural that the judges should crown works of that school more frequently than the brilliant experiments of an innovator. The hostile criticism of Aristophanes was witty; and, what has not always been observed, it was true, granting the premise from which Aristophanes starts, that the tragedy of Æschylus and Sophocles is the only right model. Its unfairness, often extreme, consists in ignoring the changing conditions of public feeling and taste, and the possibilities, changed accordingly, of an art which could exist only by continuing to please large audiences. It has usually been supposed that the unsparing derision of the comic poets contributed not a little to make the life of Euripides at Athens uncomfortable; and there is certainly one passage (in a fragment of the *Melanippe*,—Nauck, *Frag.* 495) which would apply well enough to his persecutors:—

> ἀνδρῶν δὲ πολλοὶ τοῦ γέλωτος οὕνεκα
> ἀσκοῦσι χάριτας κερτόμους· ἐγὼ δέ πως
> μισῶ γελοίομς οἵτινες· σοφῶν πέρι
> ἀχάλιν' ἔχουσι στόματα.
> To raise vain laughter, many exercise
> The arts of satire; but my spirit loathes
> These mockers whose unbridled mockery
> Invades grave themes.

The infidelity of two wives in succession is alleged to explain the poet's tone in reference to the majority of their sex, and to complete the picture of an uneasy private life. He appears to have been repelled by the Athenian democracy, as it tended to become less the rule of the people than of the mob. Thoroughly the son of his day in intellectual matters, he shrank from the coarser aspects of its political and social life. His best word is for the small farmer (*autourgos*) who does not often come to town, or soil his rustic honesty by contact with the crowd of the market-place.

About 409 B.C. Euripides left Athens, and after a residence in the Thessalian Magnesia, repaired, on the invitation of King Archelaus, to the Macedonian court, where Greeks of distinction were always welcome. In his *Archelaus* Euripides celebrated that legendary son of Têmenus, and head of the Têmenid dynasty, who had founded Ægæ; and in one of the meagre fragments he evidently alludes to the beneficent energy of his royal host in opening up the wild land of the North. It was at Pella, too, that Euripides composed or completed, and perhaps produced, the *Bacchæ*. Jealous courtiers, we are told, contrived to have him attacked and killed by savage dogs. It is odd that the fate of Actæon should be ascribed, by legend, to two distinguished Greek writers, Euripides and Lucian; though in the former case at least the fate has not such appropriateness as the Byzantine biographer discovers in the latter, on the ground that its victim "had waxed rabid against the truth." The death of Euripides, whatever its manner, occurred in 406 B.C., when he was seventy-four. Sophocles followed him in a few months, but not before he had been able to honor the memory of his younger rival by causing his actors to appear with less than the full costume of the Dionysiac festival. Soon afterwards, in the *Frogs*, Aristophanes pronounced the epitaph of Attic Comedy on Attic Tragedy.

Death, 406 B.C.

The historical interest of such a life as that of Euripides consists in the very fact that its external record is so scanty —that, unlike Æschylus or Sophocles, he had no place in the public action of his time, but dwelt apart as a student and a thinker. He has made his Medea speak of those who, through following quiet paths, have incurred the reproach of apathy (ῥαθυμίαν). Undoubtedly enough of the old feeling for civic life remained to create a prejudice against one who held aloof from the affairs of the city. Quietness (ἀπραγμοσύνη), in this sense, was still regarded as akin to indolence (ἀργία). Yet just here we see how truly Euripides was the precursor of that near future which, at Athens, saw the more complete divergence of society from the state. His work is his biography. The first requisite for a just appreciation, both of the artist and of the man, is rightly to apprehend the conditions under which his work was done.

Relation of his work to his age.

In an age which is not yet ripe for reflection or for the subtle analysis of character, people are content to express in general types those primary facts of human nature which strike every one. Achilles will stand well enough for the young chivalrous warrior, Odysseus for the man of resource and endurance, even without such elaboration of detail as would enable us surely to recognize the very man—to say, if we met him, this is the Achilles, the Odysseus, whose exact portrait we know. The poetry of such an age presents types rather than individuals. In the case of the Greeks, these types had not merely an artistic and a moral interest; they had, further, a religious interest, because the Greeks believed that the epic heroes, sprung from the gods, were their own ancestors. Direct lineage was the ground on which the Greeks trusted that the Greek gods would help them against other men, speaking barbarian tongues, and other gods, the progenitors of barbarians. Greek Tragedy arose when the choral worship of Dionysus, the god of physical rapture, had engrafted upon it a dialogue between actors who represented some persons of the legends consecrated by this faith. Now, in order that the representation should express these persons without transgressing the typical character of the legends themselves, and thereby straining or lowering this faith, it is necessary to observe a limit. The dramatist was obliged to refrain from multiplying those minute touches which, by individualizing the characters too highly, would bring them closer, indeed, to daily experience, but would detract from their general value as types in which all Hellenic humanity could recognize its own image glorified and raised a step nearer to the immortal gods. This necessity was further enforced by the existence of the Chorus, the original element of the drama, and the very essence of its nature as an act of Dionysiac worship. Those utterances of the Chorus, which to the modern sense are so often platitudes, were not so to the Greeks, just because the moral issues of Tragedy were felt to have the same typical generality as these comments themselves.

Artistic limit of tragedy.

The chorus.

An unerring instinct keeps both Æschylus and Sophocles within the limits imposed by this law. Euripides was only fifteen years younger than Sophocles. But when Euripides began to write it must have been clear to any man of his genius and culture that, though an established prestige might be maintained, a new poet who sought to construct Tragedy on the old basis would be building on sand. For, first, the popular religion itself—the very foundation of Tragedy—had been undermined. Secondly, scepticism had begun to be busy with the legends which that religion consecrated. Neither gods nor heroes commanded all the old unquestioning faith. Lastly, an increasing number of the audience in the theatre began to be destitute of the training, musical and poetical, which had prepared an earlier generation to enjoy the chaste and placid grandeur of ideal Tragedy.

New conditions with which Euripides had to deal.

His effort to meet them.

Euripides made a splendid effort to maintain the place of Tragedy in the spiritual life of Athens by modifying its interests in the sense which his own generation required. Could not the heroic persons still excite interest if they were made more real,—if, in them, the passions and sorrows of everyday life were portrayed with greater vividness and directness? And might not the less cultivated part of the audience at least enjoy a thrilling plot, especially if taken from the home-legends of Attica? Euripides became the virtual founder of the Romantic Drama. In so far as his work fails, the failure is one which probably no artistic tact could then have wholly avoided. The frame within which he had to work was one which could not be stretched to his plan. The chorus, the masks, the narrow stage, the conventional costumes, the slender opportunities for change of scenery, were so many fixed obstacles to the free development of Tragedy in the new direction. But no man of his time could have broken free from these traditions; in attempting to do so he must have wrecked either his fame or his art. It is not the fault of Euripides if in so much of his work we feel the want of harmony between matter and form. Art abhors compromise; and it was the misfortune of Attic Tragedy in his generation that nothing but a compromise could save it. A word must be said on the two devices which have become common phrases of reproach against him—the prologue, and the *deus ex machinâ*. Doubtless the prologue is a slipshod and sometimes ludicrous expedient. But it should be remembered that the audiences of his days were far from being so well versed as their fathers in the mythic lore, and that, on the other hand, a dramatist who wished to avoid trite themes had now to go into the by-ways of mythology. A prologue was often perhaps desirable or necessary for the instruction of

Obstacles to his success.

The prologue.

The *deus ex machinâ.*

The chorus.

the audience. As regards the *deus ex machinâ,* a distinction should be observed between those cases in which the solution is really mechanical, as in the *Andromache* and perhaps the *Orestes,* and those in which it is warranted or required by the plot, as in the *Hippolytus* and the *Bacchæ.* The choral songs in Euripides, it may be granted at once, have often nothing to do with the action. But the chorus was the greatest of difficulties for a poet who was seeking to present drama of romantic tendency in the plastic form consecrated by tradition. So far from censuring Euripides on this score, we should be disposed to regard his management of the chorus as a signal proof of his genius, originality, and skill.

Works.

In a poetical career of about fifty years Euripides is said to have written 92 dramas, including 8 satyr-plays. The best critics of antiquity allowed 75 as genuine. Nauck has collected 1117 Euripidean fragments. Among these, numbers 1092–1117 are doubtful or spurious; numbers 842–1091 are from plays of uncertain title; numbers 1–841 represent fifty-five lost pieces, among which some of the best known are the *Andromeda, Antiope, Bellerophon, Cresphontes, Erectheus, Œdipus, Phaethon,* and *Telephus.*

Alcestis.

(1.) The *Alcestis,* as the didascaliæ tells us, was brought out in Ol. 85. 2, *i.e.,* at the Dionysia in the spring of 438 B.C., as the fourth play of a tetralogy comprising the *Cretan Women,* the *Alcmæon at Psôphis,* and the *Telephus.* The *Alcestis* is altogether removed from the character, essentially grotesque, of a mere satyric drama. On the other hand, it has features which distinctly separate it from a Greek tragedy of the normal type. First, the subject belongs to none of the great cycles, but to a byway of mythology, and involves such strange elements as the servitude of Apollo in a mortal household, the decree of the fates that Admetus must die on a fixed day, and the restoration of the dead Alcestis to life. Secondly, the treatment of the subject is romantic and even fantastic,—strikingly so in the passage where Apollo is directly confronted with the dæmonic figure of Thanatos. Lastly, the boisterous, remorseful, and generous Heracles makes — not, indeed, a satyric drama — but a distinctly satyric scene — a scene which, in the frank original, hardly bears the subtle interpretation which in *Balaustion* is hinted by the genius of Mr. Browning, that Heracles got drunk in order to keep up other people's spirits. When the happy ending is taken into account, it is not surprising that some should have called the *Alcestis* a tragi-comedy. But we cannot so regard it. The slight and purely incidental strain of comedy is but a moment of relief between the tragic sorrow and terror of the opening and the joy, no less solemn, of the conclusion. In this respect, the *Alcestis* might more truly be compared to such a drama as the *Winter's Tale;* the loss and recovery of Hermione by Leontes do not form a tragi-comedy because we are amused between-whiles by Autolycus and the clown. It does not seem improbable that the *Alcestis*—the earliest of the extant plays—may represent an attempt to substitute for the old satyric drama an after-piece of a kind which, while preserving a satyric element, should stand nearer to Tragedy. The taste and manners of the day were perhaps tiring of the merely grotesque entertainment that old usage appended to the tragedies; just as, in the sphere of comedy, we know from Aristophanes that they were tiring of broad buffoonery. An original dramatist may have seen an opportunity here. However that may be, the *Alcestis* has a peculiar interest for the history of the drama. It marks in the most signal manner, and perhaps at the earliest moment, that great movement which began with Euripides,—the movement of transition from the purely Hellenic drama to the romantic.

Medea.

(2.) The *Medea* was brought out in 431 B.C. with the *Philoctetes,* the *Dictys,* and a lost satyr-play called the *Reapers* (*Theristæ*). Euripides gained the third prize, the first falling to Euphorion, the son of Æschylus, and the second to Sophocles. If it is true that Euripides modelled his *Medea* on the work of an obscure predecessor, Neophron, at least he made the subject thoroughly his own. Hardly any play was more popular in antiquity with readers and spectators, with actors, or with sculptors. Ennius is said to have translated and adopted it. We do not know how far it may have been used by Ovid in his lost tragedy of the same name; but it certainly inspired the rhetorical performance of Seneca, which may be regarded as bridging the interval between Euripides and modern adaptations. We may grant at once that the *Medea* of Euripides is not a faultless play; that the dialogue between the heroine and Ægeus is not happily conceived; that the murder of the children lacks an adequate dramatic motive; that there is something of a moral anti-climax in the arrangements of Medea, before the deed, for her personal safety. But the *Medea* remains a tragedy of first-rate power. It is admirable for the splendid force with which the character of the strange and strong-hearted woman, a barbarian friendless among Hellenes, is thrown out against the background of Hellenic life in Corinth. Those modern versions of the drama which have recently been illustrated by actresses of genius develop the romantic element beyond the limit of Euripides; he has nothing like the wavering and the final obedience to a Greek instinct of the children who have to make their choice — who slowly and silently turn away from their barbarian mother, and move towards the outstretched arms of Jason. Yet the essential motive of the pathos there is true to the Greek poet's conception. It is the profound contrast between the Greek and the non-Greek nature—the hopeless isolation in Greece of the alien who has left everything to follow Jason—that Euripides has drawn with such mastery. It may be asked, Could either Æschylus or Sophocles, in their different manifestations of the genuinely Hellenic spirit, have shown this more cosmopolitan sympathy, this insight into the strength and the anguish of a nature not Hellenic? Here, too, Euripides belongs to the coming time.

Hippolytus.

(3.) The extant *Hippolytus*—sometimes called *Stephanephoros,* the "wreath-bearer," from the garland of flowers which, in the opening scene, the hero offers to Artemis—was not the first drama of Euripides on this theme. In an earlier play of the same name, we are told, he had shocked both the moral and the æsthetic sense of Athens. In this earlier *Hippolytus,* Phædra herself had confessed her love to her step-son, and, when repulsed, had falsely accused him to Theseus, who doomed him to death; at the sight of the corpse, she had been moved to confess her crime, and had atoned for it by a voluntary death. This first *Hippolytus* is cited as *Hippolytus the Veiled* (*καλυπτόμενος*), either, as Toup and Welcker thought, from Hippolytus covering his face in horror, or, as Bentley with more likelihood suggested, because the youth's shrouded corpse was brought upon the scene. It can scarcely be doubted that the chief dramatic defect of our *Hippolytus* is connected with the unfavorable reception of its predecessor. Euripides had been warned that limits must be observed in the dramatic portrayal of a morally repulsive theme. In the later play, accordingly, the whole action is made to turn on the jealous feud between Aphrodite, the goddess of love, and Artemis, the goddess of chastity. Phædra not only shrinks from breathing her secret to Hippolytus, but destroys herself when she learns that she is rejected. But the natural agency of human passion is now replaced by a supernatural machinery; the slain son and the bereaved father are no longer the martyrs of sin, the tragic witnesses of an inexorable law; rather they and Phædra are alike the puppets of a divine caprice, the scapegoats of an Olympian quarrel in which they have no concern. But if the dramatic effect of the whole is thus weakened, the character of Phædra is a fine psychological study; and, as regards form, the play is one of the most brilliant. Bœckh (*De Tragædiae Græc. Principiis,* p. 180 f.) is perhaps too ingenious in finding an allusion to the plague at Athens (430 B.C.) in the *ὦ κακὰ θνητῶν στυγεραί τε νόσοι* of v. 177, and in v. 209 f.: but it can scarcely be doubted that he is right in suggesting that the closing words of Theseus (v. 1460)

> ὦ κλείν' 'Αθηνῶν Παλλάδος θ'ὁρίσματα οἵου στερησεσθ' ἀνδρος,

and the reply of the chorus, *κοινὸν τόδ' ἄχος,* etc., contain a reference to the recent death of Pericles (429 B.C.)

Hecuba.

(4.) The *Hecuba* may be placed about 425 B.C. Thucydides (iii. 104) notices the purification of Delos by the Athenians, and the restoration of the Panionic festival there, in 426 B.C.—an event to which the choral passage, v. 462 f., probably refers. It appears more hazardous to take v. 650 f. as an allusion to the Spartan mishap at Pylos. The subject of the play is the revenge of Hecuba, the widowed queen of Priam, on Polymestor, king of Thrace, who had murdered her youngest son Polydorus, after her daughter Polyxena had already been sacrificed by the

Greeks to the shade of Achilles. The two calamities which befall Hecuba have no direct connection with each other. In this sense it is an unanswerable objection that the play lacks unity of design. On the other hand, both events serve the same end,—viz., to heighten the tragic pathos with which the poet seeks to surround the central figure of Hecuba. The chief interest of the drama consists in its illustration of the skill with which Euripides, while failing to satisfy the requirements of artistic drama, could sustain interest by an ingeniously woven plot. It is a representative *Intriguenstück*, and well exemplifies the peculiar power which recommended Euripides to the poets of the New Comedy.

Andromache. (5.) The *Andromache*, according to a notice in the *Scholia Veneta* (446), was not acted at Athens, at least in the author's life-time; though some take the words in the Greek argument (*τὸ δρᾶμα τῶν δευτέρων*) to mean that it was among those which gained a second prize. The invective on the Spartan character which is put into the mouth of Andromache contains the words, *ἀδίκως εὐτυχεῖτ' ἂν 'Ελλάδα*, and this, with other indications, points to the Peloponnesian successes of the years 424–422 B.C. Andromache, the widow of Hector, has become the captive and concubine of Neoptolemus, son of Achilles. During his absence, her son Molossus is taken from her, with the aid of Menelaus, by her jealous rival Hermione. Mother and son are rescued from death by Peleus; but meanwhile Neoptolemus is slain at Delphi through the intrigues of Orestes. The goddess Thetis now appears, ordains that Andromache shall marry Helenus, and declares that Molossus shall found a land of Epirote kings, while Peleus shall become immortal among the gods of the sea. The *Andromache* is a poor play. The contrasts, though striking, are harsh and coarse, and the compensations dealt out by the *deus ex machinâ* leave the moral sense wholly unsatisfied. Technically the piece is noteworthy as bringing on the scene four characters at once—Andromache, Molossus, Peleus, and Menelaus (v. 545 f.).

Ion. (6.) The *Ion* is an admirable drama, the finest of those plays which deal with legends specially illustrating the traditional glories of Attica. It is also the most perfect example of the poet's skill in the structure of dramatic intrigue. For its place in the chronological order there are no data except those of style and metre. Judging by these, Hermann would place it "neither after Ol. 89, nor much before"—*i.e.*, somewhere between 424 and 421 B.C.; and this may be taken as approximately correct. The scene is laid throughout at the temple of Delphi. The young Ion is a priest in the temple of Delphi when Xuthus and his wife Creusa, daughter of Erechtheus, come to inquire of the god concerning their childlessness; and it is discovered that Ion is the son of Creusa by the god Apollo. Athena herself appears, and commands that Ion shall be placed on the throne of Athens, foretelling that from him shall spring the four Attic tribes, the Teleontes (priests), Hopletes (fighting-men), Argadeis (husbandmen) and Aigikoreis (herdsmen). The play must have been peculiarly effective on the Athenian stage, not only by its situations, but through its appeal to Attic sympathies.

Suppliants. (7.) The *Suppliants* who give their name to the play are Argive women, the widows of Argive warriors slain before the walls of Thebes, who, led by Adrastus king of Argos, come as suppliants to the altar of Demeter at Eleusis. Creon, king of Thebes, has refused burial to their dead lords. The Athenian king Theseus demands of Creon that he shall grant the funeral rites; the refusal is followed by a battle in which the Thebans are vanquished, and the bodies of the Argive dead are then brought to Eleusis. At the close the goddess Athena appears, and ordains that a close alliance shall be formed between Athens and Argos. Some refer the play to 417 B.C., when the democratic party at Athens rose against the oligarchs. But a more probable date is 420 B.C., when, through the agency of Alcibiades, Athens and Argos concluded a defensive alliance. The play has a strongly marked rhetorical character, and is, in fact, a panegyric, with an immediate political aim, on Athens as the champion of humanity against Thebes.

Heracleidæ. (8.) The *Heracleidæ*,—a companion piece to the *Suppliants*, and of the same period,—is decidedly inferior in merit. Here, too, there are direct references to contemporary history. The defeat of Argos by the Spartans in 418 B.C. strengthened the Argive party who were in favor of discarding the Athenian for the Spartan alliance (Thuc. v. 76). In the *Heracleidæ*, the sons of the dead Heracles, persecuted by the Argive Eurystheus, are received and sheltered at Athens. Thus, while Athens is glorified, Sparta, whose kings are descendants of the Heracleidæ, is reminded how unnatural would be an alliance between herself and Argos.

Heracles Mainomenos. (9.) The *Heracles Mainomenos*, which, on grounds of style, can scarcely be put later than 420–417 B.C., shares with the last two plays the purpose of exalting Athens in the person of Theseus. Heracles returns from Hades,—whither, at the command of Eurystheus, he went to bring back Cerberus,—just in time to save his wife Megara and his children from being put to death by Lycus of Thebes, whom he slays. As he is offering lustral sacrifice after the deed, he is suddenly stricken with madness by Lyssa (Fury), the dæmonic agent of his enemy the goddess Hera, and in his frenzy he slays his wife and children. Theseus finds him, in his agony of despair, about to kill himself, and persuades him to come to Athens, there to seek grace and pardon from the gods. The unity of the plot may be partly vindicated by observing that the slaughter of Lycus entitled Heracles to the gratitude of Thebes, whereas the slaughter of his own kinsfolk made it unlawful that he should remain there; thus, having found a refuge only to lose it, Heracles has no hope left but in Athens, whose praise is the true theme of the entire drama.

Iphigenia among the Tauri. (10.) *Iphigenia among the Tauri*, which metre and diction mark as one of the later plays, is also one of the best,—excellent both in the management of a romantic plot and in the delineation of character. The scene is laid at the temple of Artemis in the Tauric Chersonese (the Crimea)—on the site of the modern Balaclava. Iphigenia, who had been doomed to die at Aulis for the Greeks, had been snatched from that death by Artemis, and had become priestess of the goddess at the Tauric shrine, where human victims were immolated. Two strangers, who had landed among the Tauri, have been sentenced to die at the altar. She discovers in them her brother Orestes and his friend Pylades. They plan an escape,—are recaptured,—and are finally delivered by the goddess Athene, who commands Thoas, king of the land, to permit their departure. Iphigenia, Orestes, and Pylades return to Greece and establish the worship of the Tauric Artemis at Brauron and Halæ in Attica. The drama of Euripides necessarily suggests a comparison with that of Goethe; and many readers will probably also feel that, while Goethe is certainly not inferior in fineness of ethical portraiture, he has the advantage in his management of the catastrophe. But it is only just to Euripides to remember that, while his competitor had free scope of treatment, he, a Greek dramatist, was bound to the motive of the Greek legend, and was obliged to conclude with the foundation of the Attic worship.

Troades. (11.) The *Troades* appeared in 415 B.C. along with the *Alexander*, the *Palamedes*, and a satyr-play, the *Sisyphus*. It is a picture of the miseries endured by noble Trojan dames,—Hecuba, Andromache, Cassandra,—immediately after the capture of Troy. There is hardly a plot in the proper sense,—only an accumulation of sorrows on the heads of the passive sufferers. The piece is less a drama than a pathetic spectacle, closing with the crash of the Trojan towers in flame and ruin. The *Troades* is indeed remarkable among Greek tragedies for its near approach to the character of melodrama. It must be observed that there is no ground for the inference—sometimes made an accusation against the poet—that the choral passage, v. 794 f., was intended to encourage the Sicilian expedition, sent forth in the same year (415 B.C.). The mention of the "land of Ætna over against Carthage" (v. 220) speaks of it as "renowned for the trophies of prowess,"—a topic, surely, not of encouragement but of warning.

Helena. (12.) The *Helena*—produced, as we learn from the Aristophanic scholia, in 412 B.C., the year of the lost *Andromeda*,—is not one of its author's happier efforts. It is founded on a strange variation of the Trojan myth, first adopted by Stesichorus in his Palinode—that only a wraith of Helen passed to Troy, while the real Helen was detained in Egypt. In this play, she is rescued from the Egyptian king, Theoclymenus, by a ruse of her husband Menelaus, who brings her safely back to Greece. The romantic element thus engrafted on the Greek myth is more than fantastic: it is well-nigh grotesque. We are, in fact, dangerously close to the verge of parody. The comic poets

—notably Aristophanes in the *Thesmophoriazusæ*—felt this; nor can we blame them if they ridiculed a piece in which the mode of treatment was so discordant with the spirit of Greek tradition, and so irreconcilable with all that constituted the higher meaning of Greek Tragedy.

Phœnissæ.

(13.) *Phœnissæ* was brought out, with the *Œnomaus* and the *Chrysippus*, in 411 B.C., the year in which the recall of Alcibiades was decreed by the army at Samos, and, after the fall of the Four Hundred, ratified by the Assembly at Athens (Thuc. viii. 81, 97). The dialogue between Iocaste and Polyneices on the griefs of banishment (*τί τὸ στέρεσθαι πατρίδος*, v. 388 f.) has a certain emphasis which certainly looks like an allusion to the pardon of the famous exile. The subject of the play is the same as that of the Æschylean *Seven against Thebes*—the war of succession in which Argos supported Polyneices against his brother Eteocles. The Phœnician maidens who form the chorus are imagined to have been on their way from Tyre to Delphi, where they were destined for service in the temple, when they were detained at Thebes by the outbreak of the war—a device which affords a contrast to the Æschylean chorus of Theban elders, and which has also a certain fitness in view of the legends connecting Thebes with Phœnicia. But Euripides has hardly been successful in the rivalry—which he has even pointed by direct allusions—with Æschylus. The *Phœnissæ* is full of brilliant passages, but it is rather a series of effective scenes than an impressive drama.

Electra.

(14.) Plutarch (*Lys.* 15) says that, when Athens had surrendered to Lysander (404 B.C.) and when the fate of the city was doubtful, a Phocian officer happened to sing at a banquent of the leaders the first song of the chorus in the *Electra* of Euripides—

> Ἀγαμέμνονος ὦ κόρα,
> ἤλυθον, Ἠλέκτρα, ποτὶ σὰν ἀγροτέραν αὐλάν,

and that "when they heard it, all were touched, so that it seemed a cruel deed to destroy for ever the city so famous once, the mother of such men." The character of the *Electra*, in metre and in diction, seems to show that it belongs to the poet's latest years. If Müller were right in referring to the Sicilian expedition the closing passage in which the Dioscuri declare that they haste "to the Sicilian sea, to save ships upon the deep" (v. 1347), then the play could not be later than 413 B.C. But it may with more probability be placed shortly before the *Orestes*, which in some respects it much resembles: perhaps in or about the year 410 B.C. No play of Euripides has been more severely criticised. The reason is evident. The *Choephori* of Æschylus and the *Electra* of Sophocles appear to invite a direct comparison with this drama. But, as the present writer has ventured to suggest elsewhere,[1] such criticism as that of Schlegel should remember that works of art are proper subjects of direct comparison only when the theories of art which they represent have a common basis. It is surely unmeaning to contrast the elaborate homeliness of the Euripidean *Electra* with the severe grandeur of its rivals. Æschylus and Sophocles, as different exponents of an artistic conception which is fundamentally the same, may be profitably compared; Euripides interprets another conception, and must be tried by other principles. His *Electra* is, in truth, a daring experiment—daring, because the theme is one which the elder school had made peculiarly its own. We are unable to share Hartung's enthusiasm for the success of the experiment. But we protest against the injustice of trying it by a standard foreign to the poet's aim.

Orestes.

(15.) The *Orestes*, acted in 408, bears the mark of the age in the prominence which Euripides gives to the assembly of Argos,—which has to decide the fate of Orestes and Electra,—and to rhetorical pleading. The plot proceeds with sufficient clearness to the point at which Orestes and Electra have been condemned to death. But the later portion of the play, containing the intrigues for their rescue and the final achievement of their deliverance, is both too involved and too inconsequent for a really tragic effect. Just as in the *Electra*, the heroic persons of the drama are reduced to the level of commonplace. There is not a little which borders on the ludicrous, and it can be seen how easy would have been the passage from such tragedy as this to the restrained parody in which the Middle Comedy delighted. It is, however, inconceivable that, as some have supposed, the *Orestes* can have been a deliberate compromise between tragedy and farce. It cannot have been meant to be played, as a fourth piece, instead of a regular satyric drama. Rather it indicates the level to which the heroic tragedy itself had descended under the treatment of a school which was at least logical. The celebrity of the play in the ancient world,—and, as Mr. Paley observes, there are more ancient quotations from the *Orestes* than from all the extant plays of Æschylus and Sophocles together—is perhaps partly explained by the unusually frequent combination in this piece of striking sentiment with effective situation.

Iphigenia at Aulis.

(16.) The *Iphigenia at Aulis*, like the *Bacchæ*, was brought out only after the death of Euripides. It is a very brilliant and beautiful play,—probably left by the author in an unfinished state,—and has suffered from interpolation more largely, perhaps, than any other of his works. As regards its subject, it forms a prelude to the *Iphigenia in Tauris*. Iphigenia has been doomed by her father Agamemnon to die at Aulis, as Calchas declares that Artemis claims such a sacrifice before the adverse winds can fall.

The genuine play, as we have it, breaks off at v. 1508, when Iphigenia has been led to the sacrificial altar. A spurious epilogue, of wretched workmanship (v. 1509–1628), relates, in the speech of a messenger, how Artemis saved the maiden. We may, however, congratulate ourselves on possessing, even in its present form, so large a part of this fine work, probably the latest upon which Euripides was engaged.

Bacchæ.

(17.) The *Bacchæ*, unlike the preceding play, appears to have been finished by its author, although it is said not to have been acted, on the Athenian stage at least, till after his death. It was composed, or completed, during the residence of Euripides with Archelaus, and in all probability was originally designed for representation in Macedonia,—a region with whose traditions of orgiastic worship the Dionysus myth was so congenial. The play is sometimes quoted as the *Pentheus*. It has been justly observed that Euripides seldom named a piece from the chorus, unless the chorus bore an important part in the action or the leading action was divided between several persons. Possibly, however, in this instance he may designedly have chosen a title which would at once interest the Macedonian public. *Pentheus* would suggest a Greek legend about which they might know or care little. The *Bacchæ* would at once announce a theme connected with rites familiar to the northern land.

It is a magnificent play, alone among extant Greek tragedies in picturesque splendor, and in that sustained glow of Dionysiac enthusiasm to which the keen irony lends the strength of contrast. If Euripides had left nothing else, the *Bacchæ* would place him in the first rank of poets, and would prove his possession of a sense rarely manifested by Greek poets,—perhaps by no one of his own contemporaries in equal measure except Aristophanes,—a feeling for natural beauty lit up by the play of fancy. Mr. R. V. Tyrrell, in his edition of the *Bacchæ*, has given the true answer to the theory that the *Bacchæ* is a recantation. Euripides had never rejected the facts which formed the basis of the popular religion. He had rather sought to interpret them in a manner consistent with belief in a benevolent Providence. The really striking thing in the *Bacchæ* is the spirit of contentment and of composure which it breathes, —as if the poet had ceased to be vexed by the seeming contradictions which had troubled him before. Nor should it be forgotten that, for the Greek mind of his age, the victory of Dionysus in the *Bacchæ* carried a moral even more direct than the victory of Aphrodite in the *Hippolytus*. The great nature-powers who give refreshment to mortals cannot be robbed of their due tribute without provoking a nemesis. The refusal of such a homage is not, so the Greeks deemed, a virtue in itself: in the sight of the gods it may be only a cold form of ὕβρις, overweening self-reliance—the quality personified in Pentheus.

The *Bacchæ* was always an exceptionally popular play, —partly because its opportunities as a spectacle fitted it for gorgeous representation, and so recommended it for performance at courts and on great public occasions. "Demetrius the Cynic" (says Lucian) "saw an illiterate person at Corinth reading a very beautiful poem,—the *Bacchæ* of Euripides, I think it was; he was at the place where the messenger narrates the doom of Pentheus and the deed of

---

[1] Introduction to the *Electra* of Sophocles, p. xiii., in *Catena Classicorum*, 2d edit.

Agave. Demetrius snatched the book from him and tore it up, saying, 'it is better for Pentheus to be torn up at once by me than to be mangled over and over again by you.'"

Cyclops.

(18.) The *Cyclops*, of uncertain date, is the only extant example of a satyric drama. The plot is taken mainly from the story of Odysseus and Polyphemus in the 9th book of the *Odyssey*. In order to be really successful in farce of this kind, a poet should have a fresh feeling for the nature of the art parodied. It is because Euripides was not in accord with the spirit of the heroic myths that he is not strong in mythic travesty. His own tragedies,—such as the *Helen*, the *Electra*, and the *Orestes*,—had, in their several ways, contributed to destroy the meaning of satyric drama. They had done gravely very much what satyric drama aimed at doing grotesquely. They had made the heroic persons act and talk like ordinary men and women. The finer side of such parody had lost its edge; only broad comedy remained.

Rhesus.

(19.) The *Rhesus* is still held by some to be what the didascaliæ and the grammarians call it,—a work of Euripides; and Mr. Paley has ably supported this view. But the scepticism first declared by Valcknär has steadily gained ground, and the *Rhesus* is now almost universally recognized as spurious. The art and the style, still more evidently the feeling and the mind, of Euripides are absent. If it cannot be ascribed to a disciple of his matured school, it is still less like the work of an Alexandrian. The most probable view seems to be that which assigns it to a versifier of small dramatic power in the latest days of Attic Tragedy. It has this literary interest, that it is the only extant play of which the subject is directly taken from our *Iliad*, of which the tenth book,—the Δολώνεια,—has been followed by the playwright with a closeness which is sometimes mechanical.

Literary history of Euripides.

Alexandria.

Influence of Euripides on Hellenism.

When the first protests of the comic poets were over, Euripides was secure of a wide and lasting renown. As the old life of Athens passed away, as the old faiths lost their meaning and the peculiarly Greek instincts in art lost their truth and freshness, Æschylus and Sophocles might cease to be fully enjoyed save by a few; but Euripides could still charm by qualities more readily and more universally recognized. The comparative nearness of his diction to the idiom of ordinary life rendered him less attractive to the grammarians of Alexandria than authors whose erudite form afforded a better scope for the display of learning or the exercise of ingenuity. But there were two aspects in which he engaged their attention. They loved to trace the variations which he had introduced into the standard legends. And they sought to free his text from the numerous interpolations which even then had resulted from his popularity on the stage. Philochorus (about 306–260 B.C.), best known for his *Atthis*, dealt, in his treatise on Euripides, especially with the mythology of the plays. From 300 B.C. to the age of Augustus, a long series of critics busied themselves with this poet. The first systematic arrangement of his reputed works is ascribed to Dicæarchus and Callimachus in the early part of the 3d century B.C. Among those who furthered the exact study of his text, and of whose work some traces remain in the extant scholia, were Aristophanes of Byzantium, Callistratus, Apollodorus of Tarsus, Timachidas, and pre-eminently Didymus; probably also Crates of Pergamos and Aristarchus. At Rome Euripides was early made known through the translations of Ennius and the freer adaptations of Pacuvius. When Hellenic civilization was spread through the East, the mixed populations of the new settlements welcomed a dramatic poet whose taste and whose sentiment were not too severely or exclusively Attic. The Parthian Orodes and his court were witnessing the *Bacchæ* of Euripides when the Agave of the hour was suddenly enabled to lend a ghastly reality to the terrible scene of frenzied triumph by displaying the gory head of the Roman Crassus. Mommsen has noted the moment as one in which the power of Rome and the genius of Greece were simultaneously abased in the presence of sultanism. So far as Euripides is concerned, the incident may suggest another and a more pleasing reflection; it may remind us how the charm of his humane genius had penetrated the recesses of the barbarian East, and had brought to rude and fierce peoples at least some dim and distant apprehension of that gracious world in which the great spirits of ancient Hellas had moved. A quaintly significant testimony to the popularity of Euripides is afforded by a strange composition, probably of the 4th century A.D., the Χριστὸς πάσχων. This drama, narrating the events which preceded and attended the Passion, is a cento of no less than 2610 verses, taken from the plays of Euripides, principally from the *Bacchæ*, the *Troades*, and the *Rhesus*. The traditional ascription of the authorship to Gregory of Nazianzus is now generally rejected; a more probable conjecture assigns it to Apollinaris of Laodicea, and places the date of composition at about 330 A.D. Although the text used by the author of the cento may not have been a good one, the value of the piece for the diplomatic criticism of Euripides is necessarily very considerable; and it was diligently used both by Valcknär and by Porson.

The Χριστὸς πάσχων.

Dante's mention of Euripides.

Dante, who does not mention Æschylus or Sophocles, places Euripides, with the tragic poets Antiphon and Agathon, and the lyrist Simonides, in the first circle of Purgatory (xxii. 106), among those

Racine.

Milton.

18th-century revival of feeling for Greek art.

Reaction against Euripides.

Schlegel.

Tieck.

Casaubon, in a letter to Scaliger, salutes that scholar as worthy to have lived at Athens with Aristophanes and Euripides—a compliment which certainly implies respect for his correspondent's powers as a peace-maker. In popular literature, too, where Æschylus and Sophocles were as yet little known, the 16th and 17th centuries testify to the favor bestowed upon Euripides. Gascoyne's *Jocasta*, played at Gray's Inn in 1566, was a free transcript from the *Phœnissæ*. Among early French translations from Euripides, may be mentioned the version of the *Iphigenia in Tauris* by Sibilet in 1549, and that of the *Hecuba* by Bouchetel in 1550. About a century later Racine gave the world his *Andromaque*, his *Iphigénie*, and his *Phèdre;* and many have held that, at least in the last-named of these, "the disciple of Euripides" has excelled his master. Bernhardy notices that the performance of the *Hippolytus* at Berlin in 1851 seemed to show that, for the modern stage, the *Phèdre* has the advantage of its Greek original. Racine's great English contemporary seems to have known and to have liked Euripides better than the other Greek tragedians. In the *Reason of Church Government* Milton certainly speaks of "those dramatic constitutions in which Sophocles and Euripides reign;" in the preface to his own drama, again, he joins the names of Æschylus, Sophocles, and Euripides,—"the three tragic poets unequalled yet by any." But the *Samson Agonistes* itself clearly shows that Milton's chief model in this kind was the dramatist whom he himself has called—as if to suggest the skill of Euripides in the delineation of pathetic women—"sad Electra's poet;" and the work bears a special mark of this preference in the use of Euripidean monodies. In the second half of the 18th century such men as Winckelmann (1717–1768) and Lessing (1729–1781) gave a new life to the study of the antique. Hitherto the art of the old world had been better known through Roman than through Greek interpreters. The basis of the revived classical taste had been Latin. But now men gained a finer perception of those characteristics which belong to the Greek work of the great time, a fuller sense of the difference between the Greek and the Roman genius where each is at its best, and generally a clearer recognition of the qualities which distinguish ancient art in its highest purity from modern romantic types. Euripides now became the object of criticism from a new point of view. He was compared with Æschylus and Sophocles as representatives of that ideal Greek tragedy which ranges with the purest type of sculpture. Thus tried, he was found wanting; and he was condemned with all the rigor of a newly illuminated zeal. Niebuhr (1776–1831) judged him harshly; but no critic approached Schlegel (1767–1845) in severity of one-sided censure. Schlegel, in fact, will scarcely allow that Euripides is tolerable except by comparison with Racine. Tieck (1773–1853) showed truer appreciation for a brother artist, when he described the work of Euripides as the dawn of a romantic poetry haunted by dim yearnings and forebodings. Goethe—who, according to Bernhardy, knows Euripides only "at a great distance" (der ihn aus weiter Ferne kennt)—certainly admired him highly, and has left an interesting memorial of Euripidean study in his attempted reconstruction of the lost *Phaethon*. There are some passages in Goethe's conversations with Eckermann which form effective quotations against the Greek poet's real or supposed detractors. "To feel and respect a great personality, one must be something one's self. All those who denied the sublime to Euripides were either poor wretches incapable of comprehending such sublimity, or shameless charlatans, who, in their presumption, wished to make more of themselves than they were." "A poet whom Socrates called his friend, whom Aristotle lauded, whom Alexander admired, and for whom Sophocles and the city of Athens put on mourning on hearing of his death, must certainly have been some one. If a modern man like Schlegel must pick out faults in so great an ancient, he ought only to do it upon his knees." (Symonds, *Greek Poets*, i. 230.) We yield to no one in admiration of Goethe; but we cannot think that these rather bullying utterances are favorable examples of his method in æsthetic discussion; nor have they any logical force except as against those—if there be any such—who deny that Euripides is a great poet. One of the most striking of recent criticisms on Euripides is the sketch by Mommsen in his history of Rome. It is, in our opinion, less than just to Euripides as an artist. But it indicates, with true historical insight, his place in the development of his art, the operation of those external conditions which made him what he was, and the nature of his influence on succeeding ages.

Goethe.

Mommsen.

Manuscript tradition of Euripides.

The manuscript tradition of Euripides has a very curious and instructive history. It throws a suggestive light on the capricious nature of the process by which some of the greatest literary treasures have been saved or lost. Nine plays of Euripides were selected, probably in early Byzantine times, for popular and educational use. These were,—*Alcestis, Andromache, Hecuba, Hippolytus, Medea, Orestes, Phœnissæ, Rhesus, Troades.* This list includes at least two plays, the *Andromache* and the *Troades*, which, even in the small number of the extant dramas are universally allowed to be of very inferior merit—to say nothing of the *Rhesus*, which is generally allowed to be spurious. On the other hand, the list omits at least three plays of first-rate beauty and excellence, the very flower, indeed, of the extant collection—the *Ion*, the *Iphigenia in Tauris*, and the *Bacchæ*—the last certainly, in its own kind, by far the most splendid work of Euripides that we possess. Had these three plays been lost, it is not too much to say that the modern estimate of Euripides must have been decidedly lower. But all the ten plays not included in the select list had a narrow escape of being lost, and, as it is, have come to us in a much less satisfactory condition.

The nine plays.

Kirchhoff's account of the MSS.

Kirchhoff has been the first, in his editions, thoroughly to investigate the history and the affinities of the Euripidean manuscripts. All our MSS. are, he thinks, derived from a lost archetype of the 9th or 10th century, which contained the nineteen plays (counting the *Rhesus*) now extant. From this archetype a copy, also lost, was made about 1100 A.D., containing only the nine select plays. This copy became the source of all our best MSS. for those plays. They are,—(1) Marcianus 471, in the library of St. Mark at Venice (12th century); *Andromache, Hecuba, Hippolytus* (to v. 1234), *Orestes, Phœnissæ;* (2) Vaticanus 909, 12th century, nine plays; (3) Parisinus 2712, 13th century, 7 plays (all but *Troades* and *Rhesus*). Of the same stock, but inferior, are (4) Marcianus 468, 13th century: *Hecuba, Orestes, Medea* (v. 1–42), *Orestes, Phœnissæ;* (5) Havniensis (from *Hafniæ*, Copenhagen, according to Mr. Paley), a late transcript from a MS. resembling Vat. 909, nine plays. A second family of MSS. for the nine plays, sprung from the same copy, but modified by a Byzantine recension of the 13th century, is greatly inferior.

MSS. of the nine plays.

MSS. of the other plays.

The other ten plays have come to us only through the preservation of two MSS., both of the 14th century, and both ultimately derived, as Kirchhoff thinks, from the archetype of the 9th or 10th century. These are (1) Palatinus 287, Kirchoff's B, usually called Rom. C., thirteen plays, viz., six of the select plays (*Androm., Med., Rhes., Hipp., Alc., Troad.*) and seven others—*Bacchæ, Cyclops, Heracleidæ, Supplices, Ion, Iphigenia in Aulide, Iphigenia in Tauris;* and 2 Flor. 2, Elmsley's C., eighteen plays, viz., all but the *Troades*. This MS. is thus the only one for the *Helena*, the *Electra*, and the *Hercules Furens*.

MSS. of three plays.

By far the greatest number of Euripidean MSS. contain only three plays,—the *Hecuba, Orestes,* and *Phœnissæ*—these having been chosen out of the select nine for school use—probably in the 14th century.

It is to be remembered that, as a selection, the nine chosen plays of Euripides correspond to those seven of Æschylus and those seven of Sophocles which alone remain to us. If, then, these nine did not include the *Iphigenia in Tauris*, the *Ion*, or the *Bacchæ*, may we not fairly infer that the lost plays of the other two dramatists comprised works at least equal to any that have been preserved? May we not even reasonably doubt whether we have received those masterpieces by which their highest excellence should have been judged?

Scholia.

The extant scholia on Euripides are for the nine select plays only. The first edition of the scholia on seven of these plays (all but the *Troades* and *Rhesus*) was published by Arsenius—a Cretan whom the Venetians had named as bishop of Monemvasia, but whom the Greeks had refused to recognize—at Venice, in 1534. The scholia on the *Troades* and *Rhesus* were first published by L. Dindorf, from Vat. 909, in 1821. The best complete edition is that of W. Dindorf, in 4 vols., 1863. The collection, though loaded with rubbish—including worthless analyses of the lyric metres by Demetrius Triclinius—includes some invaluable comments derived from the Alexandrian critics and their followers.

Editions.

Editiones principes.—1496, J. Lascaris (Florence), *Medea, Hippolytus, Alcestis, Andromache.* 1503, M. Musurus (Aldus, Venice) *Eur. Tragg.* XVII., to which in vol. ii. the *Hercules Furens* was added as an 18th; *i.e.*, this edition contained all the extant plays except the *Electra*, which was first given to the world by P. Victorius from Florentinus C. in 1545. The Aldine edition was reprinted at Basel in 1537.

The complete edition of Joshua Barnes (1694) is no longer of any critical value. The first thorough work done on Euripides was by L. C. Valcknär in his edition of the *Phœnissæ* (1755), and his *Diatribe in Eur. perditorum dramatum relliquias* (1767), in which he argued against the authenticity of the *Rhesus*.

Principal editions of selected plays.—J. Markland (1763–1771): *Supplices, Iphigenia A., Iphigenia T.*—Ph. Brunck (1779–1780): *Andromache, Medea, Orestes, Hecuba.*—R. Porson (1797–1801): *Hecuba, Orestes, Phœnissæ, Medea.*—H. Monk (1811–1818): *Hippolytus, Alcestis, Iphigenia A., Iphigenia T.*—P. Elmsley (1813–1821): *Medea, Bacchæ, Heraclidæ, Supplices.*—G. Hermann (1831–1841) *Hecuba* (*animadv. ad R. Porsoni notas*, first in 1800), *Orestes, Alcestis, Iphigenia, A., Iphigenia T., Helena, Ion, Hercules Furens.*—C. Badham (1851–1853): *Iphigenia T., Helena, Ion.*—R. Y. Tyrrell (1871): *Bacchæ.*—For young students: A. Sidgwick (1871–1873): *Cyclops, Electra, Ion, Iphigenia T.*

Recent Complete Editions.—W. Dindorf (1870, in *Poet. Scenici*, ed. 5).—A. Kirchhoff (1867).—F. A. Paley (1872, 2d. ed.) with commentary.

English Translations.—R. Potter.—*Bacchæ:* Milman, Thorold Rogers, E. S. Shuckburgh.—*Medea:* Mrs. Webster.—*Alcestis* (a "Transcript," in *Balaustion*): R. Browning.—*Hecuba* ("A Trojan Queen's Revenge"): Beesley.

Goethe's reconstruction of Euripides's lost *Phaethon*, in the 1840 edition of his works, vol. 33, pp. 22–43. (R. C. J.)

EUROPA, in Greek mythology, a daughter of Agenor, or, as some said, of Phœnix. According to the story, she was born in Phœnicia, the purple land, a region belonging to the same aërial geography with Lycia, Delos, Ortygia, Lycosura, and many others. When Phœnicia became to the Greeks the name of an earthly country, versions of the myth were not long wanting which asserted that Agenor was born in Tyre or Sidon. Agenor, it is said, was the husband of Telephassa; but Telephassa is the feminine form of the name Telephus, a word conveying precisely the same meaning with Hecatus, Hecate, Hecatebolus, well known epithets of the sun and moon. The beauty of Europa attracted to her the love of Zeus, who approached her in the form of a white bull, and carried her away to Crete, where she became the mother of Minos, Rhadamanthus, and Sarpedon. Meanwhile her brother Cadmus, under a

strict charge never to return without her, set out on the weary search with his mother Telephassa, who died on the plains of Thessaly. At Delphi he learnt that he must follow a cow which would guide him to the place where he must build the city. The cow lay down on the site of Thebes; but before he could offer the animal as a sacrifice to Athene, he had to fight with the dragon which haunted the well. Cadmus alone could conquer it; and he did so, like Apollo, in single combat, while the dragon's teeth which he sowed produced a harvest of armed men who slew each other, leaving five only to become the ancestors of the Thebans. Athene now made him king of Thebes, while Zeus gave him Harmonia as his bride. According to one version of the tale, Cadmus and his wife, at the end of their career, were changed into dragons, and so taken up to Elysium. The names in this myth may seem to explain themselves completely by a comparison with those of other Greek legends. Among these are Agenor, Telephassa, Sarpedon. Others are not less clearly Semitic, Cadmus being the ground form of the Semitic Kedem, the East, just as Melicertes reproduces the Syrian Melcarth or Moloch.

Plate IX.

EUROPE is the smallest of those divisions of the land-surface of the globe which are usually distinguished by the conventional name of continents; but favored as it is at once by its position, its configuration, and its climate, it has played the most important part in the modern history of the world, more especially since the 16th century. The ultimate civilization of mankind must in great measure be what Europe makes it; and though, as centuries roll on, the auxiliary energies of other regions and races, receiving new impulse and development, will undoubtedly lend potent contributions to the common historic movement, the period must still be distant when Europe shall have fallen from its position of controller and pioneer. It has justly become a commonplace of geography to describe it as a mere peninsula of Asia, but, except in a purely geographical aspect, it is a peninsula as the head is a peninsula of the body. Its individuality and its solidarity with the neighboring continents, its originality and its indebtedness, must be equally emphasized if a just conception is to be formed of its characteristics. All its dominant and, perhaps, nearly all its distinguishable peoples, its languages, its religions, its philosophies, its social organizations, have had their origin outside of its boundaries, and have been forced by modern science to recognize their kindred elsewhere. But under its modifying influences everything has been deeply and permanently differentiated; its people are more thoroughly conscious of their dissimilarities from, than of their consanguinity with, the peoples of the East and the South; its dominant religion at least has in large measure forgotten or belied its original character and scope; its philosophies have taken coloring and shape from the practical and political life of the people; and its social organizations have been disintegrated and reformed under the pressure of new necessities and desires. And in a way in which they have never been realized before, it has within the present century realized two master principles of progress—the regularity of nature and its amenability to multiplex investigation and control, and the necessity of impartial recognition at once of the moral individuality of the individual and the social and political solidarity of the several members of the community.

Though Europe is naturally the best known of all the regions of the globe, yet even of its physical features an absolutely correct registration has not been attained. It is the only continent of which we possess an approximately complete cartography; but in spite of the geodetic labors which have been carried on since about the middle of last century with ever growing activity, much has still to be laid down on very unsatisfactory data. While in some districts, for instance, of England or France, we can find on our maps the exact locality of every hamlet or homestead, every streamlet or clump of trees, there are portions of several other countries where the main physical features are but vaguely indicated. A considerable part of Finland is practically unexplored; and it was not until 1875 that the labors of Kanitz furnished a fair representation of the Balkan range. Nor is it only about such outlying regions as Turkey and Finland that our information is either scanty or of the most recent acquisition; the topographical survey of Switzerland, which first provided the Alpine traveller with an authentic guide, was completed by Dufour only in 1865, and the corresponding surveys of England, Italy, Spain, Russia, etc., are still in progress. Till the last country in Europe has been thus triangulated, we must be content with more or less approximate estimates of areas and distances; in two recent statements of the area of Portugal there is a difference of no less than 104 English square miles (4·89 German geog. sq. m., or 269·05 sq. kil.), so that the possible error for the whole of the continent must be something considerable. Even the astronomical distance between Paris and Berlin cannot be given with absolute accuracy.

Boundaries.

Owing to its peninsular conformation the present boundaries of Europe are on three sides easily stated: its western shores form the irregular rim of the great basin of the North Atlantic, and bear witness in their dilapidated headlands and sandy dunes to the power and fury of its tides and storms; on the N. it lies along the Arctic Ocean; and on the S. it is separated from Africa and Asia by the Mediterranean, the Sea of Marmora, the Black Sea, and their connecting straits. Towards the east, on the other hand, the boundary is almost purely conventional: the Ural Mountains, indeed, may be regarded as furnishing a sort of natural barrier, but they leave a considerable gap both towards the N. and the S. In the S. the river Ural is usually accepted as the line of demarcation, though the plain through which it flows is perfectly similar on both sides, and it forms neither a geological, faunal, botanical, political, nor historical limit. In the administrative divisions of the Russian empire, which has no desire to make a severe distinction between its Asiatic and European territory, even the line of the Ural Mountains is disregarded: 39,545 square miles (1860·02 German geog. sq. miles, 102,418·1 sq. kil.) of the government of Orenburg, 49,333 square miles (2320·425 German geog. sq. m., 127,769·3 sq. kil.) of the government of Perm, and 297·6 sq. miles (14 Germ. geog. sq. m., 812·9 sq. kil.) of the government of Ufa lie to the E. of the range. Across the peninsula between the Black Sea and the Caspian the line of the Caucasus is now accepted as the boundary. The British islands have been separated from the Continent in a comparatively recent geological period, and really form the prominences of a submerged plateau which at one time must have presented a long and regular coast to the Atlantic. Iceland, though distant more than 600 miles, and geologically, it may be, of independent origin, is usually reckoned as an outlying portion of Europe. Nova Zemlya and Waigatch may also be included; but Spitzbergen is more accurately assigned to the Arctic archipelago. In the Mediterranean the Balearic islands are conventionally attached to Spain, Corsica to France, and Sardinia, Sicily, and the Pantellarian grouplet to Italy. Malta is also regarded as European. Among the central islands of the great archipelago between the Balkan peninsula and Asia Minor it is hard to find a line of demarcation; but the Cyclades, as part of the kingdom of Greece, may be considered to belong to the western, and the rest of the islands to the eastern continent. Properly speaking, they are both Asiatic and European, and for that very reason neither European nor Asiatic.

Extent.

The four corners of Europe are marked by the mouth of the Kara on the Arctic Ocean in the N.E., 69° N. lat. and 65° E. long.; by the North Cape on the Arctic Ocean in the N.W., 71° 11′ N. lat. and 25° 50′ E. long.; by Cape Tarifa on the Atlantic in the S.W., 36° N. lat. and 5° 36′ W. long.; and by Cape Apsheron on the Caspian Sea in the S.E., 40° 12′ N. lat. and 50° 20′ E. long. Its most northern point as a continent is Cape Nordkun in Norway, 71° 7′ N. lat.; its most southern, Cape Matapan in Greece, 36° 24′ N. lat.; its most western, Cape da Roca in Portugal, 9° 31′ W. long.; and its most eastern, a spot at the junction of the Ural range with the Grossland's Ridge in 66° E. long. A line drawn from Cape St. Vincent in Portugal to the Ural Mountains near Ekaterinburg has a length of 3293 miles, and finds its centre in the W. of Russian Poland. From the mouth of the Kara to the mouth of the Ural river the direct distance is 1600 miles, but the boundary line has a length of 2400 miles. The total area of the continent, according to Behm and Wagner's calculation, is 179,833·37 German sq. miles, 9,902,149 sq. kilometres, or 3,823,383·32 English sq. miles; so that it forms rather more than a thirteenth part of the whole land surface of the globe. Asia is about 4½ times, and America about 4⅛ times as large. The total population in round numbers is 309,178,300, which gives an average of 1719 for the German mile, 31·2 for the square kilometre, and 80·8 for the English sq mile—considerably more than the average of any other of the continents.

Coast-line.

Two of the most striking features in the general conformation of Europe are the great number of its primary and secondary peninsulas, and the consequent exceptional development of its coast line,—an irregularity and development which have been the most potent of the physical factors of its history. The peninsulas which are of most historic interest are those which trend southward into the Mediterranean:—the Balkan peninsula terminating in the wonderful cluster of peninsulas and islands which bears the name of Greece, the long Italian peninsula with Sicily at its foot, and the massive Pyrenean peninsula, so thoroughly shut off by its mountain isthmus that in ordinary language it is distinguished as the Peninsula par excellence. The northern peninsulas are much less symmetrical in their arrangement, and have exercised less influence on the history of Europe. The total coast-line is estimated at 19,820 miles, of which about 3600 belong to the Arctic Ocean, 8390 to the Atlantic, and 7830 to the Black Sea and Mediterranean. This gives 1 mile of coast to 192 miles of area, which is a higher rate than that of any of the other continents. Much of this coast-line, more especially in Norway and Spain, is of course practically useless as far as commerce is concerned, owing to the absence of natural harbors; but even when such portions are withdrawn, the facilities for maritime activity are exceptionally great. That so small a part of the total belongs to the Arctic Ocean, which lies ice-bound during many months of the year, and so large a part to the Mediterranean, with its comparative freedom from winter and storm, has been of no small importance to the progress of the European peoples.

Changes of coast-line.

The coast-line of Europe is in its general features very much the same as it was at the commencement of the true historic period; but when it is examined in detail it is found to have undergone a number of important local changes, some at least of which are due to causes that are at work over very extensive areas. These changes may be conveniently classified under four heads:—The formation of deltas by the alluvium of rivers; the increase of the land-surface due to upheaval; the advance of the sea by reason of its own erosive activity; and the advance of the sea through the subsidence of the land. The actual form of the coast, however, is frequently due to the simultaneous or successive action of several of the causes—sea and river and subterranean forces helping or resisting each other. Our information is naturally most complete in regard to the Mediterranean coasts, as these were the best known to our first book-writing nations. There we find that all the great rivers have been successfully at work—more especially the Rhone, the Ebro, and the Po. The activity of the Rhone, indeed, as a maker of new land, is really astonishing. The tower of St. Louis, erected on the coast in 1737, is now upwards of four miles inland; the city of Arles is said to be nearly twice as far from the sea as it was in the Roman period. The present St. Gilles was probably a harbor when the Greeks founded Marseilles, and Aigues Mortes, which took its place in the Middle Ages, was no longer on the coast in the time of St. Louis. According to a calculation quoted by M. Reclus, the total alluvium of the river in the space of a year is 17,000,000 cubic metres, or 590,000,000 cubic feet; and this estimate is supported by M. Reybert, who found that the new land formed between 1841 and 1859 implied an annual deposit of nearly 19,000,000 cubic metres, or 671,000,000 cubic feet. The increase of the land is observable, not only in the immediate neighborhood of the mouth, but round almost the whole of the gulf of Lyons, and is, of course, partly due to the alluvium of minor rivers. At the mouth of the Hérault, according to Fischer,[1] the coast advances at least two metres or about seven feet annually; and it requires great labor to keep the harbor of Cette from being silted up. The Po is even more efficient than the Rhone, if the size of its basin be taken into account. Were it not counteracted in some measure, it would soon with the assistance of the Isonzo, the Adige, and the neighboring streams, turn the northern part of the Adriatic into a plain. Ravenna, which was at one time an insular city like Venice, has now a wide stretch of downs partly covered with pine forest between it and the sea. Aquileia, one of the greatest seaports of the Mediterranean in the early centuries of the Christian era, is now 7 miles from the coast, and Adria, which gives its name to the sea, is 13. And this increase of the land has gone on in spite of the fact that both cities are on the northern part of an area of subsidence which apparently extends southwards along the whole Dalmatian coast. The islands on which Venice is built have sunk about three feet since the 16th century: the pavement of the square of St. Mark's has frequently required to be raised, and the boring of a well has shown that a layer of vegetable remains, indicating a flora identical with that observed at present on the neighboring mainland, exists at a depth of 400 feet below the alluvial deposits. At Zara ancient pavements and mosaics are found below the sea-level, and the district at the mouth of the Narenta has been changed into a swamp by the advance of the sea. A process of elevation, on the other hand, is indicated along nearly all the coasts of Sicily, round the bay of Naples and the bay of Gaieta, at the southern end of Sardinia, the east of Corsica, and perhaps in the neighborhood of Nice. The borings of pholads are found at a height of 600 feet on Monte Pellegrino; the ancient harbor which gave its name to Palermo (Panormus) is now nearly covered by the modern town; and the Grotto of San Ciro, which now lies 6000 feet inland, and at a height of more than 220 feet, must have had a direct communication with the sea during the period of human occupation. That the rise thus rendered evident is taking place over a wide area is shown by similar facts observed on the African coast. The Tunisian harbor of Porto Farina, which had a depth of 30 or 40 feet in last century, can hardly be trusted for 2; and this change can only be very partially due to the action of the Medjenda river, as it brings down but little alluvium. If the movement be maintained the Mediterranean will again be divided into two basins by the old ridge between Sicily and Africa whose existence has been posited to explain the present distribution of zoological fossils. Passing eastward to the Balkan peninsula, we find considerable changes on the coast-line of Greece; but as they are only repetitions on a smaller scale of the phenomena already described, it is sufficient to indicate the Gulf of Arta and the mouth of the Spercheius as two of the more important localities. The latter especially is interesting to the historian as well as to the geologist, as the river has greatly altered the physical features of one of the world's most famous scenes—the battle-field of Thermopylæ.

If we proceed to the Atlantic seaboard we observe, as we might expect, great modifications in the embouchures of the Garonne and the Loire, but by far the most remarkable oscillations of sea and land have taken place in what are emphatically the Low Countries of Europe. It is one of the familiar facts of geography that a large part of the soil of Holland with its villages and cities is many feet below the level of the sea; but it is not so generally known that about a fifth of the area of the country is thus situated. The story of the contest carried on along the coast between man and nature has often been told, and is well worth the telling. If success is to be measured by the amount of territory acquired, nature has hitherto had the best of the battle, and no wonder, if it be true that the very ground on which man has built his ramparts against the sea is slowly sinking under his feet. Such, at least, is the opinion of Élie de Beaumont and other geologists of note: in fact the whole maritime region from the Scheldt to the Weser is an area of subsidence. The Dutchman, however, does not intend to give up the contest. It was only in 1395 that he finally lost possession of the 500,000 hectares or 1,236,570 English acres of good land which are now covered by the Zuyder Zee; and he hopes to get the best part of it back again. A scheme has been proposed by which the whole southern portion, with an area of 195,000 hectares (481,872 acres) will be inclosed by a dyke extending from Enkhuizen to Kampen; and the feasibility of the enterprise is sufficiently attested by the brilliant success of the Haarlem engineers who, at a cost of less than £765,000, have recovered the area of the Haarlem Lake which had been lost in the 16th century. Further east along the coast, between the Elbe and the Eider, it is hard to say whether land or sea is gaining: on the one hand it is stated that the ruins of the castle of Schlei are now covered by the sea, and that a forest of historic identity is totally destroyed; while on the other it is equally certain that the parish of Busum in the north part of Ditmarsh was made land-fast only in the 16th century, that the Friedrick Koog, an area of new alluvial land five miles long and two miles broad, was endyked in 1853, and that islands are being formed further out towards the sea.

---

[1] "Küstenveränderungen im Mittelmeergebiet," in *Ztschr. der Ges. für Erdkunde zu Berlin*, 1878.

The Baltic shores of Germany display the same phenomena of local gain and loss; and there is more than a suspicion that the whole line lies along an area of subsidence. In the western section the inroads of the sea have been very extensive: the island of Rügen would no longer serve for the disembarkation of an army like that of Gustavus Adolphus; Wollin and Usedom are growing gradually less; large stretches of the mainland are fringed with submerged forests; and at intervals the site of well-known villages is occupied by the sea. Towards the east the great rivers are successfully working in the opposite direction. In the gulf of Dantzic the alluvial deposits of the Vistula cover an area of 1600 square kilometres or 615 square miles; in the 13th century the knights of Marienburg inclosed with dykes 900 sq. kil., or 346 sq. m., and 180 sq. kil., or 69 sq. m., were added in the course of the 14th. The Memel is silting up the Kurische Haff, which, like the Frische Haff, is separated from the open sea by a line of dunes comparable with those of the Landes in France.

A large amount of evidence has gradually accumulated in favor of the hypothesis that the Scandinavian peninsula is in process of elevation. Within the last two centuries fiords have been left dry or broken into lakes, reefs have been turned into islands, bays into pasture grounds, M. Reclus has pointed out that the presence of certain beds of oysters goes to show that the lakes Malar, Hjelmar, and Wener are remains of a channel which at no distant date communicated between the Baltic and the North Sea; but the facts of marine distribution, as stated by Forbes, are rather against the opinion of Celsius, that there was also a connection with the Arctic Ocean as late as the time of the first Roman exploration. At Pitea, in the Gulf of Bothnia, the land is said to have gained a mile in 45 years, and at Lulea a mile in 28 years.[1]

It is only right, however, to mention that the statements made in the preceding paragraphs in regard to areas of subsidence and elevation are by several geologists considered to be of very dubious validity. The data, they believe, are much too slight and fragmentary for the conclusions, and some of the most important are open to quite different interpretations. The so-called strand or coast-lines of the Scandinavian peninsula, for example, are still the subject of keen controversy among northern investigators, and a large polemical literature is the result. Till the question as to the origin of these remarkable appearances is finally settled, the recent elevation of the peninsula must be regarded as little more than a provisional hypothesis.[2]

Volcanoes and earthquakes.

The changes briefly indicated above take place so gradually for the most part that it requires careful observation and comparison of data to establish their reality. The Dutchman does not feel the subsidence of his well-defended flats, and the Norwegian is quite unconscious that he is being raised along with his pine-clad hills. It is very different with those changes which we usually ascribe to volcanic agency: they force themselves on the attention, and find a permanent place in the memory of the people. And yet it is only the scientific registration of the phenomena which gives any accurate idea of their frequency and extent. To the popular apprehension Europe is a fairly stable portion of *terra firma*, and we are accustomed to contrast the uncomfortable tendency to oscillation exhibited by such a region as Colombia or Peru in South America. But it is not so stable as it appears. Besides the great outlying "hearth" of Iceland, there are four centres of volcanic activity in Europe—all of them, however, situated in the Mediterranean. Vesuvius on the western coast of Italy, Etna in the island of Sicily, and Stromboli in the Liparian group, have been familiarly known from the earliest historic times; but the fourth has only attracted particular attention since last century. It lies in the Archipelago, on the southern edge of the Cyclades, near the little group of islets called Santorin. The region was evidently highly volcanic at an earlier period, for Milo, one of the nearest of the islands, is simply a ruined crater still presenting smoking solfataras and other traces of former activity. The present crater of Santorin is subaqueous, but it has already raised a considerable mass of material above the surface. The devastations produced by the eruptions of the European volcanoes are usually confined within very narrow limits; and it is only at long intervals that any part of the continent is visited by a really formidable earthquake. There is little danger when the tremor has to be verified by glass cylinders on a sanded floor. Minor shocks, however, are exceedingly numerous. Dr. Volger found that during the first fifty years of the 19th century the average number per annum was, in Switzerland, no less than fifty; and he indicates the following localities as *habituellen Stossgebiete* or areas of frequent disturbance:—(1) in the region of the Jura, the valley of the Birs to the S. of Basel, the valley of the Orbe, the Val de Travers, the valley of St. Imier, the district at the confluence of the Aar and the Limmat, etc.; and (2) in the Alpine region, the valley of the Durance and the Drac, of the Arc and the Isère, nearly the whole line of the Arve, the upper valley of the Rhone almost without interruption to the Lake of Geneva, part of the valley of Adige to the S. of Trent, and the valleys of the Drave and the Gail to the W. of their confluence. A table drawn up by Dr. Suess registers about 116 earthquakes in Lower Austria from 1021 down to 1870, and of these 53 belong to the present century.[3] Of all European earthquakes in modern times, the most destructive were that of Lisbon in 1755, and that of Calabria in 1783; the devastation produced by the former has become a classical instance of such disasters in popular literature, and by the latter 100,000 people are said to have lost their lives. Calabria again suffered severely in 1865 and 1870.

Relief.

If Russia be left out of account, Europe may be generally characterized as a mountainous region,—the ratio of highlands and lowlands being, according to Von Klöden's calculation, approximately as follows:

	Total Area. English sq. miles.	Highlands. English sq. miles.	Lowlands. English sq. miles.
Continental portion, without peninsulas and islands............	2,740,100	587,412	2,152,688
Greater peninsulas	835,715	641,286	194,429
Great Britain and Ireland	115,913	60,125	55,788
Other islands	64,738	47,857	16,881

In other words, the purely continental portion has 21·44 per cent. of highlands to 78·56 per cent. of lowlands; the peninsular portion 76·74 per cent. to 23·26 per cent.; Great Britain and Ireland 51·87 per cent. to 48·13 per cent.; and the remaining islands 73·92 to 26·08. There are none of the individual mountains that attain more than a moderate elevation if they are compared with the mountains of Asia and South America. Mont Blanc, the loftiest of all, has an altitude of only 15,781 feet, while Mt. Everest, in the Himalayas, is 29,000 feet high, and Chimborazo and Aconcagua, in the Andes, are respectively 20,677 and 23,910.

Leipoldt's Table of Mean Elevation.

	Metres.	English Feet.
Switzerland..	1299·91	4264·74
Iberian Peninsula (Spain and Portugal)...	700·60	2298·52
Balkan Peninsula (Turkey and Greece)...	579·50	1901·21
Austria..	517·87	1699·02
Apennine Peninsula (Italy)	517·17	1696·73
Scandinavia	428·10	1404·51
France..	393·84	1292·11
Roumania...	282·28	926·19
Great Britain...	217·70	714·22
German Empire.....................................	213·66	700·97
Russia..	167·09	548·18
Belgium..	163·36	535·95
Denmark..	35·20	115·48
Netherlands, excluding Luxembourg and parts below sea-level......	9·61	31·52

The whole continent is formed on a small scale of relief, though this scale is not so small as has usually been stated on the authority of Humboldt. The mean elevation of Asia, according to his calculations, was 351 metres (1151 E. ft.); of South America, 344 metres (1128 E. ft.); of North America, 227 metres (744 E. ft.); and of Europe only 204 metres (669 E. ft.). In 1874 Dr. Gustav Leipoldt published the results of a new calculation, which, being carefully conducted and based on a much more extensive collection of data, must replace the estimates of Humboldt. The preceding is a table of his principal findings, giving an average of 296·838 metres, or 973·7 English feet.

---

[1] Compare Howorth "On Recent Elevations of the Earth's Surface in the Northern Circumpolar Region," in *Jour. Roy. Geog. Soc.*, 1873, and Adolf von Hoff, *Gesch. d. Veränd. d. Erdoberfläche*, 1822, 1823, 1834.

[2] Compare Keilhau *On the Rise of Land in Scandinavia*; Kjerulf, *Om Skuringsmärka, etc., i Norge*, 1872; Sexe, *On gamle Strandlinier i fast Klippe*, 1874.

[3] See *Zeitschrift der K. Academie zu Wien*, 1874 and 1875, and Petermann's *Mittheilungen*, 1856.

If the materials which are employed in producing the relief of the various countries were equally distributed over the surface of the continent, their respective contributions would arrange them in the following order:—

	Metres.	English Feet.
Russsia would raise the continent	90·46	296·7
The Iberian Peninsula	43·24	142·0
Scandinavia	33·22	108·9
Austria	32·87	107·8
The Peninsula of the Balkan	26·68	87·5
France	21·19	69·5
The Peninsula of the Apennines	15·62	51·2
The German Empire	11·91	39·0
Great Britain	7·05	23·1
Switzerland	5·40	17·7
Denmark and Iceland	5·11	16·7
Roumania	3·48	11·4
Belgium	0·49	1·6
Netherlands	0·19	·6
Total	296·83	973·7

It is noticeable that Russia stands first on the list on account of its immense area, in spite of the fact that its mean elevation is less than that of nearly every other country.

Mountains. The central ridge of Europe is formed by a complex of from thirty to fifty distinct *massifs*, which from time immemorial have borne the name of the Alps, or, if the usual etymology be correct, the White Mountains. They are closely grouped together over an area of about 74,000 or 75,000 square miles, extending from 5° to 16° E. long., and curving round from the Gulf of Lyons to the neighborhood of Vienna. According to Dr. Leipoldt, if the material of which they are composed were equally distributed over the surface of the continent it would raise the level 27·23 metres, or 89 English feet. Mount St. Gotthard, situated in 8° 36′ E. long., is usually considered as the central massif; but instead of being, as was long supposed, the highest part of the system, and consequently of the European continent, it is really overtopped by a large number of the other groups. The honor of being the loftiest summit is now, as already stated, assigned to Mont Blanc, which, in its terminal peak, named Dufour Spitz, in memory of the great surveyor of Switzerland, reaches a height of 15,781 feet. In general the mountains of the western parts of the range are loftier and more closely ranked, while those towards the east not only diminish in height but spread out over a wider area; and on the whole the southern sides are steeper than the northern. Full details of the intricate divisions of the Alps are given in a separate article. As the birth-place of its mightiest rivers, the natural barrier between its mightiest peoples, a prime factor in the distribution of its climates, and in modern times the noblest of all international "play-grounds," the Alps act a part of multiform munificence in the economy of the continent.

With the exception of the Pyrenees and its dependencies, all the mountains of southern and central Europe may be regarded as secondary portions of the general Alpine system. If it were possible with more than human reach of sight to take an outlook northwards from some commanding peak on the northern skirts of the great chain, the whole country for two hundred miles and more would appear occupied by irregular lines and groupings of mountains and hills rising from a kind of table-land, and intersected by the deep-cut valleys of the larger rivers. Towards the north-west the most conspicuous heights are those of the Jura proper, which runs parallel with the Alps, and is only separated from them by the valleys of the Rhone and the Aar, the latter a main tributary of the Rhine. The German Jura trends north-east, the Black Forest north from the eastern extremity of the Jura proper, and fronting the Black Forest on the other side of the Rhine lie the Vosges. Further north the Rhine valley is defined on the west by the Hardt, the Hochwold, the Eifel, and the Ardennes; and on the east by the Odenwald, the Westerwald, and the Taunus. North of the German Jura lie the Franconian heights, which are separated by the valley of the Main from the Spessart, the Rhön, and the Thüringerwald. From the Thüringerwald south-east run the successive clusters of the Frankenwald and the Fichtelgebirge; and from this last massif eastward extends the Erzgebirge as far as the valley of the Elbe, and south-eastwards the Böhmerwald, along the valley of the Danube. Beyond the Elbe, and forming the eastern rim of the upper basin, are the Riesengebirge and the so-called Sudetic chain, which, by its southern extremity, approaches the Carpathian mountains; and these again, in company with the Transylvanian mountains, curve south and enclose the great Hungarian plain. The Balkan to the south of the Danube is practically on the one hand a continuation of the Transylvanian range, and on the other it is connected by the mountains of Carinthia, Dalmatia, Bosnia, and Servia with the eastern extremity of the Alps. The Apennines are still more closely connected with the western extremity, and the mountains of Auvergne and the Cevennes in France may also be regarded as outliers of the system.

Several of the ranges, however, are sufficiently distinct in position and general characteristics to be treated apart. The Apennines form an uninterrupted chain extending south to the Straits of Messina. Their mean height varies from 2600 feet in one part to 6400 in another; and among the loftiest peaks are Monte Cimone, 7060; Alpe di Camporaghena, 6537; Monte Sibilla, 7188; Gransasso, 9493; La Majella, 9314; Monte Pollino, 7441; and Aspromonte, 6375. The Carpathians are about 520 miles long, and attain their greatest elevation in Butschetie, which has an altitude of 9528 feet. The declivities of the range are steepest on the southern side. The Balkans, or Hæmus, run 400 miles east and west to the south of the Danube valley. Their mean elevation is about 5000–5600 feet; but it is only from the southern side that they present a really mountainous appearance; on the northern they gradually descend by a succession of terraces, and, with few exceptions, the summits have gently rounded contours. The culminating point is Tchar Dagh, which rises to a height of about 9700 feet. Connected with the Balkans by its western extremity is the range of the Despoto Dagh, or Rhodope, which stretches eastward along the north of the Ægean, and in some points reaches a height of 8000 feet. Nearly the whole country to the south in Thessaly and Greece is occupied by irregular groups and lines of mountains and hills, among which the most important are the Pindus and Olympus. Besides the Alpine system and the secondary systems which are grouped along with it, there are several others rendered quite distinct by their position and structure.

The Pyrenees are next to the Alps in elevation. They extend across the isthmus between France and Spain for a distance of 240 miles, and are practically continued by the Cantabrian Mountains for 260 miles more. The loftiest summit, Mont Perdu, has an altitude of 11,270 feet. The south side of the Pyrenees proper is the more rugged and precipitous; but the Cantabrian Mountains present their steepest face to the north. All the minor mountain ranges of Spain are connected with each other and with the Pyrenees. The highest is the Sierra Nevada in the south. The chain of the Dovre-Fjeld, Dofrines, or Scandinavian Alps is about 1000 miles in length, and has a general elevation of from 3000 to 6000 feet. Properly speaking, it is not so much a range of mountains as a plateau, broken up by deep-cut ravines and fiords. The western side is precipitous, and the eastern descends gradually to the Gulf of Bothnia. The Urals extend from north to south through 20° of latitude, with a breadth of about 40 miles. They rise slowly from the plain on both sides, and at the place where they are crossed by the road from Moscow to Siberia the ascent and descent is hardly noticeable. A considerable proportion of the range lies between 3000 and 4000 feet above the sea; a few peaks attain an altitude of 5000; and one, Toll-pors, is not much under 5500.[1]

If the European mountains are arranged according to their greatest elevations, they rank as follows:—(1) the Swiss Alps, with their highest peaks 15,000 feet or upwards; (2) the Sierra Nevada, the Pyrenees, and Etna, about 11,000 feet; (3) the Appenines, the Corsican Mountains, the Carpathians, the Balkans, and the Despoto Dagh, from 8000 to 9000; (4) the Guadarrama, the Scandinavian Alps, the Dinaric Alps, the Greek Mountains, and the Cevennes, between 6000 and 8000; (5) the mountains of Auvergne, the Jura, the Riesengebirge, the mountains of Sardinia, Majorca, Minorca, and the Crimea, the Black Forest, the Vosges, and the Scottish Highlands, from 4000 to 6000.

Rivers.

The table given on page 602 furnishes a comparative view of the principal European streams taken in the order of their length.

In various parts of Europe, more particularly in calcareous regions, there are subterranean or partially subterranean rivers. Of these the most remarkable are the Sorgue of Vaucluse, the Touvre of Angoulême, the Timavo of Istria, and the Poik or Planina. The first has been traced for 10 or 15 miles below ground; and the Timavo when it issues from the mountain is already navigable. Along the French coast several subterranean affluents of the Mediterranean have been discovered, and some of them are evidently of considerable size. The Garonne itself, which rises in the glaciers of Mount Maladetta, passes under Mont Poumar for a distance of 4 kilometres. The subterranean course of the streams is frequently indicated by peculiar vents or pits caused by the subsidence of the soil; they are popularly known in Greece as *catavothra*, in Carinthia as *dolinas*, and in France by a great number of local names, such as *embucs*, *gourgs*, *boit-tout*, *anselmons*, etc.[1]

Europe has no Niagara, and, indeed, few of its larger rivers present anything approaching to a real cataract. The Rhine takes a plunge of about 50 feet at Schaffhausen; and there are a series of rapids in the lower course of the Dnieper and the Dniester. In Sweden the Gotha-Elf falls 100 feet at Trollhata; the Hjommel Sayka or Hare's leap of the Lulea is 250 feet high; and the Riukan Fos or "Smoking Force" at Mjösvand is no less than 800. The famous Staubbach in the neighborhood of Lauterbrunnen has a descent of 980 feet, but it is a mere brook, and in summer almost dries up; it takes its name, as is well known, from the dust-like appearance of the spray into which the water is changed by the tremendous descent.

Several of the more important rivers are of very irregular flow, and some are subject to really formidable floods. In 1877 there were disastrous inundations of the Danube: 12,000 people were rendered homeless in one of the suburbs of Buda Pesth, hundreds of houses were undermined, while villages were submerged, and large quantities of property were swept away. The floods in the Netherlands the same year were severe enough to necessitate Government help for the sufferers. Large areas in Saxony and Silesia were under water; the Elbe, the Vistula, the Nogat, and the Oder, all overflowed their banks or burst their dikes; it was feared that the whole line of railway between Thorn and Posen would be carried away, and in some districts there was considerable loss of life. If all the damage produced in this way since the beginning of the century could be calculated, it would be found to represent an enormous sum. The floods of the Loire alone, in 1856, carried off about £8,000,000 worth of property; and those in the south of France in 1875 caused a loss of about £3,000,000. In most Continental countries there have been consequently undertaken extensive engineering works, partly to prevent inundations, and partly to render the rivers more serviceable for navigation and irrigation. France has been especially active in this matter, several of her most important streams being very difficult to regulate. The Loire, for example, varies at Orleans from 25 cubic metres or 780 feet per second to 10,000 metres or 315,000 feet in the same time; the Saône, in 1855, varied from 3,825,450 cubic feet per minute to 174,086; and the Rhone at Geneva, in 1858, which was a minimum year, from 740,000 cubic feet to 195,000.[2] The engineering works have been especially successful on the Seine and Yonne, where several new methods have been tested for storing the surplus water of one season, and utilizing it during the period of deficient supply.[3] In Italy, the Po, the Arno, and the Tiber are notorious for their floods; but the first two are now among the most striking examples of a satisfactory system of embankment. At Cremona, on the Po, which is 171 miles inland and 104 feet above sea-level, the flood of 1840 rose 18 feet, that of 1855 rose 19 feet, and that of 1857 20 feet above summer low water. On the last occasion the banks above Cremona were burst, and a vast area of country was submerged; but such a disaster is now comparatively rare. For the irrigation of the Lombard plain no less than 762,838 cubic feet per minute are drawn off by the canals.

Since the city of Rome has again become the capital of Italy the attention of the Italians has been specially turned to the Tiber, and several schemes of Herculean magnitude have been discussed. Garibaldi's project was adopted by both houses of the Parliament and sanctioned by the Government in 1875. During the present century the Danube, which is the most international of European rivers, has been greatly improved as a water-way, by the rectification of its course in the neighborhood of Vienna, by the clearing of the passage of the Iron Gates, and by the maintenance of a proper channel at the delta. It is almost needless to mention the works that have been carried on for the deepening of the seaward section of all the greater rivers, and the removal of the bars at their mouths; perhaps in this department the most remarkable results are exhibited by the Clyde.

Lakes.

In the accompanying table, for which we are indebted to Glogau, the principal lakes of Europe are arranged according to their size. If we examine their distribution we find they can easily be classified into groups.

Name of Lake.	Country.	Height above sea. English ft.	German sq. miles.	English sq. miles.

The Alpine lakes break up into a southern and northern subdivision—the former consisting of Lago Maggiore, Lago di Como, Lago d'Iseo, and Lago di Garda, all connected by affluents with the system of the Po; and the latter the lake of Geneva threaded by the Rhone, Lakes Constance, Zurich, Neufchatel, Biel, and other Swiss lakes belonging to the basin of the Rhine, and a few of minor importance belonging to the Danube. As factors in the historical development of the Alpine countries the first rank must be assigned to Geneva, Constance, and Como. Next in interest to the Al-

75. Netze	Prussia, Poland	Warthe	170	207	4,613
76. Thames	England, Gloucester	German Ocean	110	202	5,102

pine group comes the Swedish—Wener, Wetter, Mälar, and Hjelmar, lying between the Baltic Sea and the Skagerrack, and nearly as famous as their Scotch and English rivals for the beauty of their scenery. The North Russian lakes, Ladoga, Onega, etc., are mainly noticeable as the largest members of what in some respects is the most remarkable system of lakes in the continent—the Finno-Russian, which consists of an almost countless number of comparatively small irregular basins formed in the surface of a granitic plateau. In Finland proper they occupy no less than a twelfth of the total area. It is impossible to take individual account of the multitudinous small lakes that diversify the surface of every country in Europe, with the partial exception of Spain; but their influence on the climate and hydrography of the continent must not be overlooked. All of them help to increase the area of evaporation, and many even of those which are almost nameless act as reservoirs for rivers. Nearly all the rivers of Sweden, for example, have their origin in a lake or tarn; and the same is the case with many of the streams of the northern Pyrenees. The total area of the lakes given in the table is no less than 28,450 square miles, or about the united area of the Netherlands and Switzerland.

A few of the number are very shallow. The Neusiedler See, for example (the Peiso Lacus of the Latins and Fertötava of the Hungarians), completely dried up in 1864, and left its bed covered for the most part with a deposit of salt.[1] Others not mentioned in the table have been partially or completely drained by human labor. The Copais in Bœotia was attacked by Greek engineers as early as the time of Alexander the Great; but the tunnels which they constructed to carry off its waters have been choked up, and the lake is again in a state of nature. Lake Fucina or Lago Celano, in the Abruzzo in Italy, was doomed to destruction by the emperor Claudius; but the works which he constructed proved ineffectual, and it was not till 1862 that a large part of the basin was turned into dry land. The progress of agriculture has greatly diminished the quantity of marsh land in Europe, and there are only one or two really extensive regions which deserve the name. Most important of all are the Minsk marshes in Russia, and on these large encroachments are gradually being made. The draining of the Pomptine marshes in Italy made Pope Pius VII. famous in the 18th century; and at the present moment those of Ferrara are sharing the same fate.

Geological formations.

Geologists have as yet come to no agreement regarding the origin of the principal mountain ranges, and still less do they furnish a consistent and connected history of the shaping of the continent. It will consequently be sufficient to indicate the general distribution of the various formations, and the more important basins of deposition for the sedimentary rocks.[2] The typical basin is that which takes its name from Paris: in it the successive stratifications are arranged in an exceptionally symmetrical manner. To the south-east lies the basin of Bordeaux, separated by a plateau of granite and gneiss; to the north, on the other side of the Channel, the London basin; and to the north-east the basin of the lower Rhine. Further east comes the basin of the lower Weser, divided into two almost independent portions by the Harz mountains; and to the south-east is the Prague basin, which presents only fragmentary remains of its sedimentary deposits. Nearly the half of European Russia belongs to the Moscow basin, which, in the south-east, is conterminous with the probably more modern basin of the Caspian. The whole of the south of the continent, from the Pyrenees to the Caucasus, belongs to the Mediterranean basin, which is one of the greatest in the world, and has its northern limit marked by the Cevennes, the Jura, the Thüringerwald, the Böhmerwald, and the Arratyne plateau. The total surface area occupied by the plutonic and metamorphic rocks is far from inconsiderable; but, with the exception of the great mass of the Scandinavian peninsula, Finland, and Lapland, and the long line of the Urals, the individual portions are of comparatively small extent. In the Spanish peninsula they stretch from Corunna south to the Tagus, appear again in the neighborhood of Evora, form the western part of the Sierra Guadarrama, and rise in islets above the Silurian formations to the south. In France they constitute, not only the great plateau already mentioned between the Paris and the Bordeaux basin, but also the massive peninsula of Brittany; and in eastern Germany they are the predominant rocks of the Erzgebirge, the Sudetic chain, the Böhmerwald, and the inclosed area. They again appear in isolated masses of considerable extent along the inner side of the Carpathians; and in Turkey they reach from Novi-Bazar to the Black Sea, and from the south of the Balkans to the Ægean. It need hardly be added that they constitute the main mass of the Alps. The only country where the Silurian rocks have a large surface area is the Spanish peninsula, and there they are mainly confined to the western half. They show a long line in the Ural range, stretch from Lake Ladoga along the south of the Gulf of Finland, rise above the Baltic in the islands of Dago, Ösel, Gottland, and Öland, and appear sporadically throughout Scandinavia. Their very name comes from the fact that they are present in England. The other Palæozoic formations—Devonian, Carboniferous, and Permian—are widely developed. In Russia they stretch from the Baltic to the Oka, and from the White Sea to Voronezh; they occupy a considerable area to the west of the lower Don, and are laid bare in the valley of the Dniester. In Western Europe they are best represented in the countries on each side of the lower Rhine, in the British Islands, and in northern Spain; but they occur here and there in several other quarters. The Secondary formations are still more extensively distributed,—the Triassic and Jurassic forming a large proportion of central Germany, a good part of France, much of England, and nearly the whole of the eastern portion of European Russia. To the Cretaceous rocks alone belong a large part of the Paris basin, part of the lower Rhine basin, all the Danish or Cimbric peninsula, the great range of the Carpathians, the Balkan range, nearly the whole of Greece, Albania, Montenegro, Dalmatia, Servia, and a wide tract in the centre of southern Russia. The Secondary are in their turn exceeded by the Tertiary formations, which furnish the continent with some of its most valuable agricultural areas. The Miocene alone occupies a considerable part of the Paris basin, part of the basins of the lower Rhine and the lower Weser, the Lombardy plain, the Hungarian plain, Galicia, and Bessarabia, not to mention the valley of the Ebro and other extensive tracts in Spain. The Pliocene is best represented in the Caspian basin and the Ponto-Caspian depression, and along the Russian coast from the Danube to the Don.

Minerals.

Europe is richly furnished with mineral wealth, and the distribution is not so irregular as might appear from the actual state of the mining industry in the different countries. For the precious metals it is mainly indebted to other quarters of the globe, but it possesses abundant stores of iron ores, lead, copper, coal, and salt. Britain, Germany, and the countries of the Austrian-Hungarian monarchy are especially distinguished by the value and variety of their deposits; and Belgium and Sweden are largely indebted for their national prosperity, the one to its coal and the other to its iron. Spain naturally ranks high in this department, but the working of its mines is in a backward condition. In the lands of the Turkish empire matters are still worse, and Greece has comparatively little to show except the silver mines of Laurion. Roumania exports salt and petroleum, and Servia, since it became independent, has begun again to work its iron and copper mines. In the Russian empire there are valuable coal-beds in the European territory, but the richest mineral area lies on the Asiatic side of the Urals.

Platinum has hitherto been obtained nowhere in Europe except in the auriferous sands in the Russian government of Perm, which yield from 900 to 1000 kilogrammes a year. Gold, on the other hand, is widely diffused, but it occurs for the most part in such insignificant quantity as not to repay the expense of collecting. The total production is about 6900 kilogrammes per annum, and by far the greater part is furnished by Russia. The gold mines of Spain were at one time famous, and there was a considerable population supported by gold-washing in Transylvania and Roumania. Silver is much more abundant than gold, but it is less extensively distributed. There are productive mines in the Erzgebirge, the Carpathians, the Urals, the Norwegian Dovre-Fjeld, and the Sierra Morena, as well as in Sardinia and England. The total yield is about 300,000 kilogrammes per annum. A considerable proportion is obtained during the working of the lead mines, which are of great importance in several countries, more especially in Spain, Germany, and Belgium, where the supply of lead exceeds the local demand. In Spain, which has a large export, the lead mines are mainly situated in Murcia, Almeria, and Jaen; in France the most important are in the Puy-de-Dôme; in Britain in Durham and Northumberland; in Austria in Carinthia, Bohemia, Tyrol, and Galicia; and in Hungary at Neusohl and Nagybánya. In the German empire, Prussia, Saxony, Brunswick, and Anhalt are most productive; and in Italy, Sardinia, Tuscany, and Lombardy. In Portugal there are 15 mines;

[1] See Ascherson, "Die Austrocknung des Neusiedler Sees," in *Z. der Ges. für Erdkunde zu Berlin*, 1865.

[2] See map in Petermann's *Mittheilungen*, 1878.

and in Turkey lead ore exists at Gallipoli, and at Olovo in Bosnia. The total amount of copper obtained throughout the continent is estimated at about 589,000 cwt. yearly. The only countries that can afford to export are Spain, Sweden, and Norway; but Germany, Britain, Russia, Belgium, and Hungary are all great producers. In Britain the mines are mainly situated in Cornwall, Devon, and Chester; in Germany they are widely distributed, but the most productive are in the districts of Merseburg and Arnsberg in Prussia; in Hungary they chiefly occur in the Carpathian mountains. Of all the Spanish mines the best known are those of Rio Tinto and Tharsis in the province of Huelva (of which the latter is capable of yielding 500,000 tons of iron pyrites annually). More than a third of all the zinc obtained in Europe is contributed by Belgium, and nearly as much is furnished by Germany. The principal Belgian mines are in the province of Liége, and the principal German mines at Oppeln in Upper Silesia. Tin is found only in a few localities. The richest mines are those of Cornwall in England, which have been worked from the earliest historic period; and next in importance are the Austrian mines in the Erzgebirge. Mercury is practically peculiar to Spain and Hungary, though it is obtained in small quantities at Vallalta in the Italian province of Belluno, at Santa Fiora in the province of Grosseto, and in Germany at Deuxponts in the Palatinate, and is also known to exist in Bosnia and Roumania. The principal Austrian mines are at Idria in Carniola, and the principal Spanish mines at Almaden and Almadalejo in Ciudad Real.

The salt production of Europe amounts to about 95,000,000 or 100,000,000, cwt. per annum. To this total no contribution is made by Finland, Sweden, Denmark, Luxembourg, Belgium, Servia, or Montenegro. It is partly procured from mines, partly from springs, and partly from salt lakes and the ocean. The most productive mines are in the Carpathians (at Wieliczka and Bochnia in East Galicia), and at Salzburg on the north side of the Alps; there are also extensive deposits in Chester and Worcester in England, in the departments of Upper Saône and Ariége in France, at Wilhelmsglück and Friedrickshall in Würtemberg, at Berchtesgaden in Bavaria, at Leopoldshall in Anhalt, at Stassfurt and Erfurt in Prussian Saxony, at Stettin in Hohenzollern; and at Sprunberg in Brandenburg, at Cardona, Pinoso, Gerry y Villanueva, in Spain, and in the districts of Prahova, Valcea, and Bacau in Roumania. Salt springs are still more widely distributed. Bay salt is largely manufactured in France, both on the Mediterranean and Atlantic seaboards; in Russia, along the coasts of the Black Sea; in Spain, at Cadiz and Torrevieja, etc.; in Italy, in Sardinia, Sicily, and Elba; in Turkey, at the mouth of the Danube, and in the island of Crete; and in Greece, in the island of Santa Maria. The salt lakes of Bessarabia alone yielded on an average 13,924,000 cwt. yearly from 1819 to 1850, and carriers come for supplies from Poland, Volhynia, Kieff, and Tchernigoff. About 230 wagons are loaded daily in the season.[1]

Full details on the European coal-fields have already been given in the article Coal, vol. vi. pp. 52–55; and the reader will find a similar account of the iron mines under Iron. Sulphur mining is one of the greatest industries of Italy and Sicily, forming, indeed, almost the exclusive means of support for Girgenti and some other towns; graphite is obtained in Bohemia and Moravia, Bavaria, England, Russia, Sweden, and Spain; alum more particularly from Scotland, Bohemia, Germany, Russia, and Spain; asphalte from Switzerland, Italy, Brunswick, Dalmatia, and Tyrol; and petroleum from the Carpathian mountains, Alsace, Lorraine, France, etc.

Table showing Statistics of the Produce of Several of the more important Metals.[1]

The years vary from 1871 to 1875, and in the case of Spain from 1869 to 1872.

[1] Based largely on data furnished by Mr. Robert Hunt, F. R. S.

Climate.

The four great determining facts in regard to the climate of Europe are these; its northern borders are within the Arctic circle; in the south its most southern points are 9 degrees of latitude from the tropic of Cancer; to the east extends for 5000 miles the continuous land surface of Asia; to the west lie the waters of the Atlantic. Of minor but by no means small importance are the presence of the Mediterranean along the south, and the peculiar character of the African continent. To the ameliorating influence of the ocean must be ascribed the main features that distinguish the climate from that of the corresponding portions of Asia, and assimilate it so largely to the insular type. Like other great masses of water, the Atlantic is less exposed to rapid thermometric oscillations than the surface of the land, and its contiguity tends to produce a similar stability. Slowly but continually it is surrendering the heat which it has gathered in the regions of the sun. Though no problem of physical geography is more keenly debated than the method by which the heat is conveyed and distributed, the fact is admitted on all hands that such conveyance and distribution does take place. Part of the work is done directly by means of currents, part indirectly by means of winds. The questions in dispute are mainly—what are the currents, how are they produced, and what is the area of their individual influence? While one physicist ascribes all the credit to the Gulf Stream, another argues that the Gulf Stream has spent both its impetus and its heat long before it approaches the European seas, and that its contributions, if there be any at all, are altogether infinitesimal. Be that as it may, the influence of the ocean as a whole is easily verified; a glance at a map with isothermal lines at once indicates its extent. The line, for instance, of 36° of mean annual temperature, which in the east of the continent passes near Orenburg, reaches as far north as 73° in the sea between Iceland and Norway. As the complement to this stands the fact that the temperature of the East Spitzbergen Sea, is still so high that no true polar ice finds its way further south than 75° N. lat. while on the American coast it is carried down to 36° N. lat. In other words, if the European conditions were the same as the American, instead of the polar ice never being seen at the North Cape, it would come sailing down past the straits of Gibraltar.[2]

Rainfall.

As regards its rainfall Europe belongs in the main to the zone which is characterized by irregularity of seasonal distribution; its southern portions to the sub-tropical zone distinguished by the dryness of its summers. The line of demarcation runs at a little distance to the north of the Spanish coast of the Bay of Biscay, continues along the northern slope of the Pyrenees, turns north-eastwards to the neighborhood of Valence on the Rhone, curves southward to Genoa, follows the line of the Northern Apennines, strikes across the Adriatic from Rimini to the neighborhood of Zara, and proceeds by way of Seraievo, Novi-Bazar, and Sofia to the coast of the Black Sea, south of Zozopoli. Within the sub-tropical zone the maximum rainfall occurs during winter in the south of Spain and Italy; during autumn and spring in central and northern Spain, the south of France, and northern and central Italy. In the zone of irregular distribution Scotland, Ireland, and western England have their maximum in winter; western France, eastern England, the coast regions of the Low Countries and Denmark, and the greater proportion of Norway have theirs in the autumn; while in eastern France, the German Empire, Austria, Hungary, Russia, and Sweden it falls in summer. The general conditions that determine the quantity of rain in a given district are well known,—the height and direction of the mountains, proximity to the coast, and so on. As most of our rain is brought by south-west and west winds, the western parts of the continent have on the whole a heavier rainfall than the eastern; though to the south of the Alps and the Pyrenees the relief of the peninsulas, and the presence of such a large secondary reservoir of evaporation as the Mediterranean, produce great irregularities. The following statistics show the influence of a western position:—

[2] See Petermann's *Mittheilungen*, 1877, p. 24, and the works of Carpenter, Croll, Dove, and Buchan.

West.	Centimetres.	Inches.	East.	Centimetres.	Inches.
Galway..........	129·5	50·9	Dublin...........	74·2	29·2
Skye.............	257·8	101·4	Aberdeen	74·8	29·4
Penzance........	105·4	42·6	London..........	62·4	24·5
Bergen...........	225·8	88·8	Christiania.....	53·7	21·1
Gothenburg....	82.7	32·4	Stockholm	40·1	15·7
Husum..........	74·8	29·4	Lübeck.........	57·0	22·4

The greatest maxima of rainfall are registered at Stye-Pass in the west of England, 189·49 inches or 481·2 centimetres, and at Seathwaite, 152·14 inches or 386·7 centimetres. Next comes Glencroe in Argyllshire, with 128·60 inches or 326·4 centimetres. The Venetian and Lombard Alps furnish such maxima as Tolmezzo 95·9 inches or 243·6 centimetres, and Sta. Maria 97·7 inches or 248·3 centimetres; and in general it may be said that the rainfall exceeds 40 inches or 100 centimetres along the whole line of the Alps from Chambery to the neighborhood of Vienna in the east, and to the sea-coast in the south, down the central ridge of the Apennines to the latitude of Gaeta, along the line of the Balkans, in the Dalmatian, Montenegrine, and Albanian highlands, all round the north and west of Spain and Portugal from Cape Roca to the eastern end of the Pyrenees, in a large proportion of Ireland, Scotland, and Western England, and throughout nearly the whole of Norway. The plateaus are usually well watered, though their maxima are much below the maxima of the mountains; but the great Iberian plateaus are an exception to the rule. The rainfall of Salamanca is only 9·4 inches or 24·0 centimetres, and that of Albacete 10·3 inches or 26·3 centimetres —a fact which is to be ascribed partly to the exhaustion of the rain-clouds by the mountains of Galicia and Portugal, and partly to the treeless condition of the table-land itself. The average throughout Sweden and the greater part of Russia, in the Hungarian plain, the northern half of Bohemia, and the district of Germany from Halle to Dantzic, ranges from 40 to 55 centimetres or 15·7 to 21·6 inches. The lower part of the basin of the Dnieper, the whole of the basin of the Don, and the country watered by the middle division of the Volga, receive no more than from 25 to 40 centimetres or 9·8 to 15·7 inches; while the great Aralo-Caspian depression, including about 100 miles of the Lower Volga, is an almost rainless region.[1]

Winds.

In western Europe by far the most prevalent wind is the S.W. or W.S.W. It represents 25 per cent. of the annual total; while the N. is only 6 per cent., the N.E. 8, the E. 9, the S. 13, the W. 17, and the N.W. 11. Of the summer total it represents 22 per cent., while the N. is 9, N.E. 8, E. 7, S.E. 7, W. 21, and N.W. 17. In south-eastern Europe, on the other hand, the prevailing winds are from the N. and E.—the E. having the preponderance in winter and autumn.[2] Of local winds the most remarkable are the Föhn, in the Alps, distinguished for its warmth and dryness; the Rothenthurm wind of Transylvania, which has similar characteristics; the boro of the upper Adriatic, so noticeable for its violence; the mistral of southern France; the Etesian winds of the Mediterranean; and the sirocco, which proves so destructive to the southern vegetation. Though it is only at comparatively rare intervals that the winds attain the development of a hurricane, the destruction of life and property which they occasion, both by sea and land, is on the aggregate of no small moment. About six or seven storms from the west pass over the continent every winter, usually appearing later in the southern districts, such as Switzerland or the Adriatic, than in the northern districts, as Scotland and Denmark. As instances of the exceptional strength which is sometimes displayed, it may be mentioned that in April, 1800, men and cattle were actually lifted from the ground by the force of the storm, and in November of the same year about 200,000 trees were blown down in the Harz mountains alone.

Snow line.

The snow-line is subject, as is well known, to great local variations. In the western and central Alps it lies about 8860 feet above the sea, and in the eastern Alps on an average about 330 feet higher. In exceptional instances, of course, the snow disappears at a much greater altitude, and even such summits as the Jungfrau (13,671 feet), the Strahlhorn (13,750), and the Chaberton are occasionally stripped completely bare. The whole range of the Pyrenees, where the line usually lies about 8950 feet on the north side and about 10,000 on the south, is sometimes in the same condition. In Norway, towards the North Cape, the snow line is 2360 feet, in the island of Seiland about 3200, on Sulitjelma about 3970, on Dovre 5540, on Jotune 4910, on Sululand 5300, and at Folgefonden 4800,—a difference of from 400 to 1000 feet being observable between the eastern and western side of the peninsula, mainly due to the more abundant precipitation on the latter. On the western side of the Caucasus the mean elevation is 11,700 feet, on the eastern 14,100. There are no nevados in the Urals, though some of the summits exceed 5000 feet in altitude. The Alps and the Scandinavian mountains are the only ranges that possess a fully developed glacier system, but both the Pyrenees and the Caucasus have individual specimens of considerable extent. The most important of the Pyrenean group are the Maladetta, the Cabrioules, the Mont Perdu, the Brèche de Roland, the Vignemale, and the Néouville glaciers.

Botany.

The principal botanical regions of Europe have already been indicated in the article DISTRIBUTION. According to Schouw's nomenclature, the Mediterranean countries belong to the region of Labiatæ and Caryophyllaceæ; the countries of northern Europe, about as far as the neighborhood of the Arctic circle, to the region of Umbelliferæ and Cruciferæ; and the small remaining portion to the region of the Saxifrages and Mosses. The varying relief of the continent, and the consequent variety of climatic conditions, give rise to many infractions of this general rule,—the most remarkable being furnished by the Alps, which are high enough to have a large arctic area, and by the steppes of Russia, which, as is well known, also afford a peculiar environment.[3] The Arctic region, whether in the Alps or elsewhere, is distinguished by the shortness of its period of vegetation and the small number of its annual plants; the north-European region has a long period of vegetation and a regular winter rest; the Mediterranean region has a long period of vernal growth, a protracted summer siesta, a short period of autumnal growth, and a winter rest varying greatly according to locality; and the steppe region has a short period of exuberant vernal growth, limited on the one hand by a severe winter, and on the other by a parching summer. The nearest approach to tropical conditions is made by the south of Spain. In the Vega of Murcia there is no set time to sow and time to reap; every month brings its fruit, and spring and autumn keep pleasant fellowship throughout the year. The ground is no sooner cleared of its crop than it is again under the plough, and within a few weeks it is green with another blade.[4]

No exact statement can be given in regard to the number of genera and species represented in the European floras.

Several districts have only been partially explored by the botanist; he not unfrequently finds it difficult to decide whether a given plant has a right to be admitted into his lists; and he is naturally more interested in estimating the comparative richness of his scientific regions than of such conventional areas as the continents. Hinds, reckoning all known species of plants at 134,000, allows 11,200 to Europe; while Friedrich Nyman, in his *Sylloge Floræ Europææ*, 1854–1855, gives 1115 genera and 9738 species according to Fries's classification, and assigns 883 genera and 8104 species to the dicotyledons, 206 genera and 1544 species to the monocotyledons, and 26 genera and 90 species to the acotyledons. In all probability the numbers, especially of the species, are below the truth. The total number of so-called useful plants cultivated in European gardens is stated by Professor Göppert at from 2400 to 2500; but a large proportion of these are mere exotics. The extent, indeed, to which this is the case, even with many species of wide distribution, is one of the most striking facts in botanical geography. The vine, the olive, the fig tree, and the mulberry were not improbably brought from Syria or Asia Minor by the Greeks; the Arabians introduced the cotton plant; the walnut and the peach are originally from Persia, the apricot from Armenia, and the sugar-cane and the orange from China. The leek and the onion, the mustard plant and the cumin, the laurel and the myrtle, are all Asiatic. For the pomegranate we are probably indebted to the Phœnicians, and the quince still bears the name which it received from the town of Cydonia in Crete. The cypress is a native of the neighborhood of Herat, the plane tree of the Taurus, the chestnut possibly of Armenia. Lucullus, the conqueror of Mithradates, brought the first cherry-tree to Europe; and some less famous Roman of the first century after Christ was the introducer of the pistachio. Maize, tobacco, and the potato are well known to be of American origin, and the same is the case with the agave and the opuntia, two of the most characteristic plants of the Mediterranean region. The scarlet oak was brought from North America to England in 1691; the cedar of Lebanon was first planted in British soil in 1683; and among recent additions are the Douglas pine from the Rocky Mountains, the deodara from the Himalayas, the *Wellingtonia gigantea* from California, and the *Eucalyptus Globulus* from Australia. The last is being planted in thousands in southern Europe, and has produced a greater sensation than perhaps any other botanical stranger. It would be easy to continue the list to an indefinite extent, and it would require to be supplemented by a list of floral additions that have taken place within historic time without the intentional intervention of man. This second class is also a numerous and continually increasing one.[1] In the neighborhood of Port Juvenal, near Montpellier, 487 exotics from America, Asia, Australia, and New Zealand were collected by Godron, and of these 52 species were new to science. The *Anacharis Alsinastrum* or *Elodea canadensis*,[2] from Canada, now luxuriates in the rivers of England and Prussia, where it was quite unknown about 1850; and the *Eriocaulon septangulare* has found a new home in the streams of Ireland. In the former instance the rapid diffusion is all the more remarkable as the plant is diœcious, and only one sex has reached Europe. It will be readily understood that if the introduction of new species into the continent is of frequent occurrence, the migration of indigenous species from district to district must be more frequent still. The plants of the higher regions are often carried down by the rivers, and effect a permanent settlement in the plains; and from time to time a foreign army leaves the seeds of a foreign flora on its camping-ground. Thus the *Campanula pusilla*, for example, has floated down from the Alps to Strasburg, and the *Bunias orientalis* has grown in the Bois de Boulogne since the Cossacks were there in 1815. There is a limit of course to such introductions and immigrations: of plants as of men it is equally true *non omnes omnia possunt*.

Cultivated plants.

The most important economical position is held by the cereals. Wheat is most extensively cultivated in Russia, Austria, the Danubian principalities, France, England, and Germany. The parallel of 57° or 58° may be taken as its northern limit, though it is grown as far north as 65°, and is found to ripen in the island of Dyro in 69° 5′. Spelt (*Triticum Spelta*) is mainly cultivated in south-western Germany, Switzerland, and Belgium. Barley is cultivated in West Finmark as far as 70°, and is part of the usual crop in all countries of the continent. Oats are more frequent in the central and northern regions; their practical polar limit is 69° 28′, though they have been known to ripen at Hammerfest in 70° 37′. Rye is an important crop in nearly all the great grain-growing countries, but it is especially in favor in the east and north; its northern limit is between 69° and 70°. Maize has been grown in 63° 15′, reaches its practical limit in 59° 55′, and is extensively cultivated only in the southern parts of the continent. Sorgho (*Sorghum saccharatum*) from China and a few other foreign cereals have been successfully introduced, but are hardly anything more than agricultural curiosities. The next place belongs to the potato, which has spread over an enormous area in central and northern Europe. It has been grown as far north as the island of Magero in 71° 7′ N. lat., or about four miles S.E. of the North Cape. The greatest producers are Germany, Belgium, Sweden, the Netherlands, Norway, and Switzerland. A considerable variety of leguminous plants are grown in Europe either for their fruit or forage—beans, pease, lupines, clover, lucerne, sainfoin, etc. The common pea (*Pisum arvense*) and the common bean (*Vicia Faba*) have their northern limits respectively at 64° 41′ and 67° 17′. A species of lupine (*Lupinus linifolius*) furnishes a substitute for coffee both in Norway and Tyrol. The vine can be grown without protection in southern Scandinavia, and has been known to ripen its grapes in the open air at Christiansund in 63° 7′; but its cultivation is of no importance north of 47½° on the Atlantic coast, 50½° on the Rhine, and from 50° to 52° in Russia. The following is the average wine-production of the several countries:—France, 42,000,000 hectolitres (or 924,000,000 gallons); Italy, 30,300,000; Austria-Hungary, 23,000,000; Spain, 20,000,000; Germany, 4,440,500; Switzerland, 1,155,000; Greece, 1,150,000; Roumania, 1,000,000; Russia, 614,000. A special Greek variety of vine is the source of the currants of commerce; it is cultivated in the Peloponnesus, Cephalonia, Zante, Ithaca, and Santa Maura, and yields an annual average export of 128,000,000 ℔. The olive, with its double crop, is one of the principal objects of cultivation in Italy, Spain, and Greece, and is not without its importance in Portugal, Turkey, and southern Austria. The average total of the oil harvest in these countries amounts to about 140,000,000 gallons; and of this Italy alone produces about 66,000,000.

Besides the turnips and other roots which furnish so much of the winter-fodder required by the northern farmer, the beet holds an important economic position in central Europe as a producer of sugar. Tobacco is extensively grown from Sicily to Sweden, but its cultivation is forbidden in England, Spain, and San Marino, and in Austria it is a state monopoly. Its northern limit is about 63° 26′. It receives special attention in Turkey, Greece, Russia, Germany, France, and Switzerland. Hemp and flax have a very wide distribution, the former furnishing a valuable export to Archangel in the north and to Italy in the south. Among all European countries Russia is the greatest producer: during their church fasts her vast population make an enormous consumption of hemp oil. Hop-growing is hardly known in the south, but forms an important industry in England, Austria, Germany, and Belgium. The plant grows wild in Norway as far north as 64° 12′. Among the exotics exclusively cultivated in the south are the sugar-cane, the cotton-plant, and rice. The first, which is found in Spain and Sicily, is of little practical moment; the second holds a secondary position in Turkey and Greece; and the third is pretty extensively grown in special districts of Italy, more particularly in the valley of the Po. Of the vast number of fruit trees which flourish in different parts of the continent only a few can be mentioned. Their produce furnishes articles of export to Austria-Hungary, Germany, France, Belgium, Italy, and Spain. In Sardinia the acorn of the *Quercus Ballota* is still used as food, and in Italy, France, and Austria the chestnut is of very common consumption. In the Mediterranean region the prevailing forms—which the Germans conveniently sum together in the expression Südfrüchte, or southern fruits—are the orange, the citron, the almond, the pomegranate, the fig, and the carob-tree. The importance of these fruits to Italy and Spain is too well known to require more than passing mention. Sicily, which was one of the great granaries of the Roman empire, is now almost a continuous orchard. In recent years a new kind of pistachio—the cacahuetes, or mani—has been cultivated in Spain, and its fruit extensively exported. The palm trees have a very limited range: the date palm (*Phœnix dactylifera*) ripens only in southern Spain with careful culture; the dwarf palm (*Chamærops humilis*) forms thickets along the Spanish coast and in Sicily, and appears less frequently in southern Italy and Greece.

---

[1] See Zeyes, *Versuch einer Geschichte der Pflanzen-Wanderung*; Blyth, *Essay on Immigration of the Norwegian Flora during alternating Rainy and Dry Periods*, 1876; Robert Brown, in *Geographical Magazine*, 1874.

[2] See K. Bolle, in *Zeitschrift für Erdk. zu Berlin*, 1865.

Such are the main economic plants of Europe; but the list might be indefinitely extended if we were to include all the plants which enter into the *flora cibaria* of the various regions—from the caper-bush of the south to the *Polygonum viviparum* and *Oxyria reniformis* consumed by the Laplanders in the north.[1]

Forests.

When the Aryan peoples began their immigration into Europe a large part of the surface must have been covered with primeval forest; for even after long centuries of human occupation the Roman conquerors found vast regions where the axe had made no lasting impression. The account given by Julius Cæsar of the Sylva Hercynia is well known: it extended, he tells us, for sixty days' journey from Helvetia eastward, and it probably included what are now called the Schwarzwald, the Odenwald, the Spessart, the Rhön, the Thüringerwald, the Harz, the Fichtelgebirge, the Erzgebirge, and the Riesengebirge. Since then the progress of population has subjected many thousands of square miles to the plough, and in some parts of the continent it is only where the ground is too sterile or too steep that the trees have been allowed to retain possession. The consumption of timber has of necessity been enormous, more especially on account of the climatic condition of the continent and the maritime activity of a large part of its inhabitants. To the dweller in the warmer regions of the earth the chief value of a tree is not unfrequently its shade; by the European its worth is as often estimated by the quantity of heat it will yield on his hearth. Several countries, where the destruction has been most reckless, have been obliged to take systematic measures to control the exploitation and secure the replantation of exhausted areas.[2] To this they have been constrained not only by lack of timber and fuel, but also by the prejudicial effects exerted on the climate and the irrigation of the country by the denudation of the high grounds. But even now, on the whole, Europe is well wooded, and two or three countries find an extensive source of wealth in the export of timber and other forest productions, such as turpentine, tar, charcoal, bark, bast, and potash.

According to the calculations of A. Bernhardt,[3] the following table gives an approximate view of the forest areas in the several countries:—

	Total Area.		Forest Area.		Population.	Proportion per Head of Total Area.		Proportion per Head of Forest Area.	
	Hectares.	Acres.	Hectares.	Acres.		Hectares.	Acres.	Hectares.	Acres.
Greece	5,010,000	12,380,411	701,500	1,733,504	1,350,000 (1863)	3·7	9·1	0·52	1·28
Turkey	52,747,460	130,346,358	12,660,000	31,284,632	18,000,000	2·9	7·1	0·70	1·72

The average proportion for all Europe being rather more than 25 per cent., four countries rise considerably higher in the scale: viz., Norway 66, Russia 31, Austria-Hungary 29·5, and Sweden 29·02; and the other rank as follows:—Germany 25·7, Turkey 24 (?), Spain 20·38, Switzerland 17·5, France 15·8, Italy, 14·39, Greece 14, Belgium 10·6, Netherlands 7, Denmark 6, Portugal 5, and Great Britain 4. Other statisticians rate the proportion for the continent at nearly a third, and arrange the states in a somewhat different order.

The Scandinavian countries have a large timber trade. In Sweden and Norway the most usual trees are coniferous; but in the former a certain number of birches, alders, and ash-trees are intermingled, and towards the south the oak and the beech occur. This last is the characteristic tree of Denmark; though some other species, which were common in the prehistoric period, are not without importance, and coniferous trees have been again introduced. The Russian forest area is mainly in the northern part of the country, but it is separated from the Arctic coast by a wide treeless belt. Towards the south there are no great stretches of woodland, and for the most part the only trees are found along the banks of the rivers. The Mennonites on the Sea of Azoff have formed plantations, and there are others in the land of the Don Cossacks. The fir-tree is found as far south as 48° N. between Novomovskovsk and Pavlograd in the government of Kharkoff.[4] The most widely distributed tree is the pine; and of the deciduous trees the most frequent are the birch, the aspen, and the oak. In the north of Russia alone the annual production of tar amounts to 297,000,000 lb. In Austria-Hungary there is still abundance of wood, especially in the Alps and the Carpathians; but in some quarters, more particularly in Transylvania, the most reckless destruction is allowed to take place. The principal trees are the pine, the fir, the beech, the oak, the larch, and the hornbeam; next come the ash, the elm, the maple, and the birch; and in the third place, the acacia, the poplar, and the *Götterbaum*. According to the Bulletin of the Geographical Society of Belgium, the value of the timber obtained on the lands of the Hungarian crown amounts annually to about £1,042,000. In Germany, the pine and fir are most frequent in the south, and the oak and birch in the west and south-west; while in the central district coniferous and deciduous trees are about equally common. In no part of Europe are the forests under more judicious management. France is most indebted to the oak, the birch, the chestnut, the fir, and the pine; but they fail to satisfy the home consumption. The poplar gives a peculiar character to its southern landscapes, and the chestnut furnishes a valuable addition to its alimentary resources. Italy has a rich variety of types—the silver fir (*Abies pectinata*) and other conifers, the *Quercus sessiliflora*, the cork-tree, and other oaks, the chestnut, the sycamore, the mountain ash, the evergreen oak. It exports manna, which is obtained from the ash tree, galls, and turpentine. Switzerland not only supplies a great internal demand for timber, but is able to contribute to foreign markets. The common trees are for the most part the same as in Austria-Hungary. In Spain and Portugal the first rank as an economic factor belongs to the cork tree, which yields in the former country about £3,820,000 worth of bark for export, and gives employment to thousands of the population. The oak, the red birch, the chestnut, the cypress, the plane, and several conifers are also of importance. In Portugal the largest individual forest—the royal domain of Leiria—consists mainly of the Bordeaux pine.

Zoology. According to the system proposed by Dr. Sclater, and adopted by Mr. Wallace, the most recent English writer on the distribution of animals, Europe belongs to the great Palæarctic Region, which also includes the most part of the continent of Asia and a broad belt along the north of Africa. The northern and central portions of Europe constitute a special sub-region, distinguished as the "European" *par excellence;* and the southern portions in conjunction with the African belt constitute the Mediterranean sub-region. The line of demarcation between these two is almost the same as that which separates the zone of sub-tropical rains from the zone of rain at all seasons of the year, the only important difference being that, while the Italian Alps and the Lombard plain belong meteorologically to the north, they are zoologically assigned to the south.

Mammals. According to Mr. Wallace, the "European" sub-region contains two distinctive genera of mammals, the *Mygale* or musk-rat and the *Rupicapra* or chamois, and its characteristic forms are the mole, the hedgehog, the shrew, the badger, the bear, the wolf, and the fox, the weasel, the otter, the hare, and the rabbit, and the dormouse. In the Mediterranean sub-region a similar position is held by the *Dama* or fallow-deer, the civet, the hyena, and the porcupine. In former geological periods not only were the Quadrumana represented in Europe by several species, but one of those, the *Dryopithecus*, discovered in the Miocene formations, probably approached nearer to man than any of the existing anthropoids. At present the only species of the order in the continent is the *Macacus inuus*, a littte monkey about a foot and a half long, which disports itself about the rock of Gibraltar, but strangely enough has Asiatic rather than African affinities. The cosmopolitan Cheiroptera or bats are well represented—no fewer than thirty species of the family *Vespertilionidæ* alone being described. Perhaps the most common species throughout central Europe is the *Vespertilio pipistrellus* or ordinary British bat, but several others, as the *Vespertilio discolor* and the *Vespertilio limnophilus*, have a wide range. Of the genus *Sorex* among the Insectivora there are at least ten species, the *Sorex tetragonurus* or common shrew inhabiting nearly every country in the continent. An Italian species, *Sorex etruscus* or *Crocidura etrusca*, is remarkable as the smallest of all known quadrupeds. Besides the *Mygale muscovitica*, already mentioned as peculiar to the European sub-region, there is another species, the *Mygale pyrenaica.* The common hedgehog (*Erinaceus europæus*) is universally distributed; and a smaller species, *E. auritus*, is found in the province of Astrakhan. The ordinary English mole, *Talpa europæa*, is unknown in Ireland, and in southern Italy gives place to the *Talpa cæca.* There are comparatively few of the larger members of the Carnivora, and their domain is continually being diminished. The brown bear, *Ursus arctus*, is still found in the Pyrenees, here and there in the Alps, in the Carpathians, and the Scandinavian mountains; and his polar cousin, the *Ursus maritimus*, is met with along the arctic coasts. To the general distribution of the badger there appears to be no exception. The glutton is for the most part confined to the forest regions of the countries that border the Arctic Ocean. The genus *Mustela* is represented, not only by the polecat and the weasel, but by the martin, the pine-martin, and the ermine, all of which are pretty familiar in most of the sub-region, though it is only in the colder countries that their value as fur-bearers is developed. The *Mustela boccamela* or honey-weasel appears to be confined to Sardinia; and it is questionable if the ferret, *Mustela furo*, introduced by man from Africa, exists in the wild condition. An important place in the fauna of Europe is still held by the wolf and the fox, the former being from its numbers the most formidable of man's feral antagonists. It will be a long time ere the more mountainous countries of the Continent can boast, like Britain and Ireland, that their last wolf is killed, and the "tabunchiks" or horse-herds of Russia will probably for many generations have to renew their annual battles with the famished packs. It is indeed asserted that since the abolition of serfdom the number of wolves has considerably increased, since the peasants are no longer obliged, as they formerly were by their landlords, to organize regular hunting expeditions. Besides the common or gray wolf, *Canis lupus*, of universal distribution, there is a black species, *Canis lycaon*, of less frequent occurrence. The jackal, *Canis aureus*, is found in southern Russia, Greece, and Turkey. There are at least four species of fox—the *Canis vulpes*, well known in western, central, and northern Europe; the *Canis melanogaster*, or black-bellied fox, familiar in Italy, Sicily, and Sardinia; the *Canis lagopus*, arctic or blue fox, whose most popular name indicates its localities; and the *Canis corsac*, whose large packs make incursions from Tartary as far west as the Volga. The civet is found in France and Spain. Of the five or six species which represent the cat tribe, or genus *Felis*, even the most widely diffused, the *Felis lynx* or common lynx is growing scarce in all except the more mountainous regions; and the *Felis borealis* or northern lynx is familiar only in Norway and Sweden. In spite of the keen pursuit to which they are subjected the seals may still be seen, though in much diminished numbers, on the shores of all European seas, including the Baltic and the Caspian. The Caspian species belongs to the same genus (*Callocephalus* of Dr. Gray) with those of the Arctic Ocean, which probably indicates that the connection between these two habitats was more recent than the connection between the Caspian and the Mediterranean. It is doubtful whether we should include the walrus in the list of European fauna, though it is common about Spitzbergen, and occasionally appears pretty far south. The next animal which presents itself in the ordinary system of classification is one of the most interesting, on account of its rapid disappearance before the march of civilization. The natural limits of the beaver were between 33° and 67° N. lat., and within that area it was formerly present in great numbers. On the coasts of the Black Sea, where it was abundant in the beginning of the Christian era, it is no longer to be found, and it is about 500 years since it disappeared from England. Its present habitats are mainly in Poland, Russia, Sweden, Finland, and Lapland; though it still built its dams in the Moldau, the Neubach, the Lansee, the Danube, and the Salzach in Austria, at least as late as 1866.[1] It has left its mark on our geographical nomenclature in such names as Biberach, Bibersburg, and Beverley. The genus *Arvicola.* or water-vole, is represented by about ten or eleven species, some of which are very widely distributed, while others are limited to very small areas—the *Arvicola nivalis* to the Alpine region, the *Arvicola destructor* to Italy. No small notoriety belongs to the members of the genus *Lemmus* on account of their strange migrations and the destructive effects of their visits. There are three or four species, the best known of which is the *Lemmus norwegicus*, or Norwegian lemming. Equally notorious for their destructive capabilities, and much more general in their distribution, are the rats and mice, which constitute the next natural order. The most prevalent species, the *Mus decumanus*, or common brown rat, was first observed in Europe in 1727, but since then has taken possession of country after country and expelled several weaker congeners. Nine species are described, including the well-known house mouse, or *Mus musculus*, and a special Iceland variety. The common hamsters, distinguished by their provident preparation for the winter, are found in Poland, Silesia, Belgium, and Alsace; and two cognate species occur in Southern Russia. The same region presents three species of *Dipus*, or jerboas. The next genus is almost peculiar to the "European" sub-region: *Spalax typhlus*, perhaps the only species, being confined to Southern Russia, Hungary, Moldavia, Greece, and Western Asia. The bobak (*Arctomys bobak*) inhabits Bukovina and the southern parts of Poland and Russia; the marmot, *Arctomys marmotta*, is restricted to the snowy regions of the Alps; and the *Arctomys citillus* is found in Austria, Bohemia, Poland, and South Russia. One species of squirrel, the *Sciurus vulgaris*, is familiar in all the wooded districts of Europe; and another, *Sciurus alpinus*, belongs to the Alps and the Pyrenees. The flying squirrel, *Pteromys sibericus*, is found in the forests of Lithuania, Lapland, and Finland. A considerable range is assigned to the dormouse, or *Myoxus*, in its three species—*Myoxus glis*, *Myoxus nitela*, and *Myoxus avellanarius*, of which the last is the most common. On the other hand, the porcupine, or *Hystrix*, is limited to Greece, Italy, and Spain. Hares and rabbits, which form the genus *Lepus*, have a very wide range, and present but little variety. The distribution of species, however, is peculiar,—the common rabbit, for example, being abundant in England, France, and Spain, but absent from Silesia, Galicia, and Russia, and a large part of Italy. The Ruminantia have suffered even more than the larger Carnivora from the encroachments of man; the aurochs (*Bos urus*) which at one time had a wide range, is now confined to Lithuania; the *Bos scoticus* exists in a half-tame condition in a few parks in England and Scotland; the ibex or steinbock is growing scarce in the Alps and Carpathians; and the musmon or wild sheep is only to be met with in Sardinia and Corsica, part of Spain, and some of the Greek islands. The chamois, however, is still fairly common in the Alps of Switzerland, France, and Germany, in the Apennines and the Carpathians, and also in Greece. The only proper antelope, *Antilope saiga*, occurs but rarely in the country to the north of the Black Sea. Fallow deer are found wild in Spain and Sardinia, but elsewhere are protected by man. The elk is still to be met with in Lithuania, Russia, and Scandinavia; the red deer in Scotland, Scandinavia, Germany, and Spain; and the roebuck (*Cervus capriolus*) in the Scottish Highlands, the Apennines, the Carpathians, and the Sierra de Segura. Of the great Pachydermatous order, which has left such abundant remains of its hippopotami, elephants, and woolly rhinoceroses in our Pleistocene formations, the only representative in a feral condition is the wild boar, or *Sus scrofa*, which is found in various regions from Spain to the Caucasus, but does not venture north of the Baltic. The larger Cetacea are growing scarce in the European seas, but the common whale, *Balæna mysticetus*, still comes as far south as the Mediterranean; and the spermaceti and the rorqual are captured in the northern regions. The dolphins, grampuses, and porpoises are pretty commonly represented throughout the various seas, now by one species now by another.

Birds.

How rich the avifauna of the European continent really is may be judged by consulting such noble monographs as those of Gould, Sharpe and Dresser, or Bree: but it must be borne in mind that it is a variable quantity, and that no monographs can long represent the exact state of the case. The extinction or introduction of mammalian species is easily observed; but the continual movements of the feathered tribes are less easily ascertained. This has been clearly shown by C. A. Westerland in his account of the geographical distribution of the birds in Sweden and Norway. He gives a great many data which prove that southern species not unfrequently move northwards, and that there is a regular tendency of Asiatic and European birds to migrate to the west; while on the other hand it is well known that western winds bring American strangers to our shores. The *Muscicapa albicollis* has been denizened in Gothland for no more than thirty years; and the *Alauda cristata*, first observed in 1833, now regularly breeds in Scania. *Emberiza rustica*, indigenous to Asia and north-eastern Europe, appeared at Haparanda in 1821, and now spends its summers in Lapland. Similar facts might be quoted for country after country and district after district. The jackdaw began to build in Murcia in Spain about 1850, and it is now one of the commonest species; in Thuringia, the magpie, once abundant, is growing rapidly scarce. Altogether, according to Degland and Gerbe's classification, there are 247 genera and 531 species more or less belonging to the continent; but of these hardly one or two are peculiarly its own. As characteristic of his northern sub-region, Mr. Wallace names the thrushes, warblers, rudlings, tits, pipits, wagtails, buntings, house-sparrows, linnets; and of the Mediterranean sub-region, the *Luscineola*, the *Pyrophthalma* (*Curruca melanocephala* of Degland), and the *Bradyptetus* or bouscarle (*Cettia* of Degland) among the Sylviidæ; *Telephonus* among the shrikes; *Halcyon* and *Ceryle* among the king-fishers; the quail-like *Turnix* among the Gallinæ; and *Gyps*, *Vultur*, and *Neophron* among the vultures. The bearded vulture, or lämmer-geier (*Gypaetos barbatus*), is the largest of European birds; it is found in gradually diminishing numbers in the French and Swiss Alps, the Ligurian mountains, the Caucasus, and perhaps the Pyrenees. *Vultur monachus* or *arrianus* is common in Sardinia, the Pyrenees, and Bessarabia; *Neophron percnopterus* in France, Switzerland, Spain, Greece, and southern Russia. The golden eagle (*Aquila chrysaetus*), which is the largest in Europe, builds equally among the rocks of the Alps, the Pyrenees, and the Grampians, and on the treeless steppes of Russia. Next in size comes the imperial eagle, which belongs to the south of the continent; and then follows a list of lesser eagles, hawks, buzzards, kites, etc., to the number of forty species more or less, the genus *Falco* alone being represented by eleven. The owl family, Strigidæ, counts ten species, noblest of which is *Bubo maximus*, the eagle-owl, or grand duc of the French, almost rivalling the golden eagle in size; it is found not only in the French mountains, but in Switzerland, Italy, Sicily, Bessarabia, and the Crimea. The passerine order is represented by a great variety of genera and species, many of which have a wide range, and are known by the most familiar names in all the countries of the continent. In direct economic importance the first place is held by the gallinaceous order, the Grallatores, and the Palmipedes, which furnish all the species that are distinguished as game, and a great many others that are largely used as food. A few of the smaller birds are thus appropriated in special districts: the lark, for example, is caught in great numbers in the neighborhood of Halle and Leipsic, and the blackbird shares a similar fate in Corsica.[1]

Fishes.

From its mountain-lakes to the surrounding ocean the waters of Europe are for the most part well stocked with fish. No complete summation has been made of the number of genera and species represented; but it is suggestive of no small variety to learn that thirty-five species have been found in the lakes of Tyrol alone, lying between 200 and 8000 feet above the level of the sea. A considerable proportion of the genera are cosmopolitan, and a still greater number range over wide areas outside of Europe. As peculiar to his "European" sub-region, Mr. Wallace mentions two genera of the perch family—the *Aspro*, and the *Percarina* of the Dniester. Among characteristic forms are the stickleback (*Gasterosteus*), found as far south as Italy; the pike (*Esox*), which ranges from Lapland to Turkey; the *Silurus* of the Swiss lakes and German rivers; and several members of the carp family or Cyprinidæ, including the carp proper (*Cyprinus*), the roach, tench, bream, bleak, etc. Of much more practical importance are the Salmonidæ, among which the salmon holds the first place. This noble fish is found in all the rivers of the Atlantic versant as far south as the Loire, and especially in Scotland, Norway, and Iceland it proves an abundant source of wealth. In southern Russia, where the river-fisheries attain a development unknown in any other part of Europe, its place is supplied by the sturgeon, the sterlet, and the sevruga, and economically at least by several species belonging to the perch family, which hold an important position in virtue of their abundance. The greatest sea fisheries of Europe are those of the German Ocean, from which England, Scotland, Norway, Holland, and France have long reaped magnificent harvests, and in which Germany has more recently begun to share. The value of the sea fish exported from Britain, Norway, and Holland is about £4,000,000 per annum. It is needless to mention the names of the principal species—herring, cod, etc.; and the conger-eels of the Channel islands, the pilchards of the Cornish coast, and the sardines of France are almost as familiarly known. In the Baltic there is great abundance of various smaller kinds of fish—more particularly the sprat, the sardine, and several members of the perch family; and some of the Salmonidæ are of considerable economic importance. No less than 300,000 tons of sardines have been caught in a single year at the mouth of the Dwina, and the Esthonians may almost be said to subsist on a fish which they name the "kilka." In the Mediterranean the tunny, the sardine, and the anchovy give existence to the most extensive fisheries—the first passing in enormous shoals from the straits of Gibraltar eastward to the Black Sea, and skirting in its passage the coasts of Sardinia, Naples, and Sicily. The people of Comacchio on the Adriatic, to the number of 5000, are supported by the capture of the mullet, the eel, and the "acquadella," which enter their lagoons from the sea by a canal, and are prevented from returning by an ingenious system of sluices and water-gates. Among the minor animals of the European seas there are none except the oyster that have the commercial importance of the trepang of the Eastern archipelago; but several species of shell-fish, urchins, and crustaceans are extensively consumed. Oyster-beds are found on most of the Atlantic coasts, and the artificial culture of the species has recently received a great development, especially in France and England: the produce of Cancale and Granville in the bay of St. Michel, of Essex and Kent, of Ostend in Belgium, and Bohuslän in Sweden are in high repute. The sponge and the coral fisheries of the Mediterranean are both vigorously pursued, the former with most success in the Ægean, and the latter on the coasts of Sardinia, Corsica, and Andalusia.[1]

---

[1] See also Fritsch, *Naturgeschichte der Vögel Europas.*

Reptiles.

Though the reptiles as a class are represented by about forty genera, the species are for the most part inconspicuous, and in no instance formidable. The three land tortoises are all confined to the south, and one of them has its only European habitat on the Caspian. There are as many fresh-water tortoises, but only one, *Emys lutaria*, reaches as far north as Prussia. The turtle is principally caught in the Mediterranean; the chameleon is peculiar to Spain; the gecko and the *Hemidactylus verruculatus* are confined to the southern regions; and the *Phyllodactylus europœus* has only been discovered in Sardinia. *Stellio vulgaris*, very common in Greece, is the only member of the large family of the Iguanidæ that exists in Europe. On the other hand, there is a great variety of lizards (Lacertidæ and Chalcidæ), and several are of wide distribution. The *Gongylus ocellatus*, or spotted skink, is found on the shores of the Mediterranean. *Anguis fragilis*, or the slow-worm, is familiar in all except the colder regions of the continent. No fewer than eighteen species of the genus *Coluber* are described,—the largest being the *Coluber elaphis*, which not unfrequently exceeds 5 feet in length, and the most widely distributed the *Coluber natrix*, or ringed snake, which does not exceed 4 feet. The *Coluber æsculapii* gives its name to the German watering-place of Schlangenbad, or Snakes' Bath. The Viperidæ are much less prolific of species; but the *Pelias berus*, or common adder, is well known in the most part of central Europe. Of the frogs and toads there are eight genera: the genus *Rana* is represented by the common and the esculent frog, the latter of which is absent only from the British Islands; the genus *Alytes* by *A. obstetricans*, which sets the example of the curious human custom of the *couvade;* and the genus *Hyla* by *H. viridis*, or the common tree-frog, whose stentorian croak may be heard in every country of the continent. The salamanders and newts are represented by five genera: the genus *Triton* contains seven species, of which *Triton cristatus* is most commonly distributed. They would bring the list of European reptiles to a close if it were not for the presence in the caves of Carinthia and Carniola of the famous *Proteus anguinus*, or *olm* of the Germans, whose history is one of the most curious of those elucidated by modern naturalists.[2]

Insects.

Insects do not play so conspicuous and ostentatious a part in Europe as in some of the warmer regions of the globe; it is only in special localities or exceptional seasons that their destructive or irritating influence becomes formidable to man. There are not many towns like Fasano, where the inhabitants have in summer to leave their usual residences to the occupancy of flies; and if the European horticulturist has a hard battle to fight with caterpillars, earwigs, and wasps, he generally succeeds in gaining a fair crop after all. The mosquito and the tarantula are the most venomous of those which attack the human species. The locust, which spreads such alarm in Africa and Asia, appears in western Europe only at intervals and in demoralized detachments; though in the south of France it is found worth while to offer a reward for the collection of the insects and their eggs. In Turkey, the Danubian principalities, and southern Russia it sometimes commits tremendous ravages; and all efforts of the agricultural population are futile to check the advance of the countless swarms. The year 1860 was unhappily distinguished by the severity of the attack. But if insects play an inconspicuous they by no means play a small part in the European regions. In the northern subregion, among the characteristic Lepidoptera, are *Parnassius, Aporia, Leucophasia, Colias, Argynnis, Vanessa;* and of the Coleoptera, *Carabidœ, Staphylinidœ*, and *Curculionidœ*, are especially abundant. The Mediterranean subregion has two peculiar genera of butterflies—*Thais* and *Doritis*, and *Anthocharis* and *Zegis* are characteristic; of the Coleoptera, *Carabidœ, Copridœ, Buprestidœ, Cantharidœ*. and *Curculionidœ* are abundant. The three insects of greatest economic importance are the silk-moth, the bee, and the cantharis. The silk-worm, since its introduction in the 6th century, has become an important object of cultivation in Italy, Turkey, Greece, France, Spain, and Portugal, and has even proved remunerative in Prussia, Bavaria, and central Russia; and recently a new species from Japan, which feeds on the oak and not on the mulberry, has been successfully reared in the Baltic provinces. Bee-keeping is an extensive industry in Italy, France, Switzerland, Russia, and Sweden; and in Greece the tax on bees furnishes £1600 to the revenue. The cantharis is a native not only of Spain, as its popular name of Spanish fly imports, but also of France, Germany, Italy, Hungary, and South Russia, and even occurs in the south of England. After the declaration of Mexican independence in 1820 the cultivation of the cochineal insect was introduced into the Spanish province of Granada with such success that no less than 801,915 ℔ of raw cochineal was exported to England in 1850. The present generation has seen two very unwelcome additions to the number of European insects—the *Phylloxera vastatrix* and *Doryphorus decemlineata* or Colorado beetle, of which the former has completely ruined a large proportion of the French vineyards, and the latter has threatened to play similar havoc with the potato crop.

Domestic animals.

The horse holds the first place among the domestic animals of Europe, and in no other region has it developed a greater variety of type. Whether the present species is of European origin has not been quite decided; but remains of a similar form occur in the Pliocene and Pleistocene strata, and it is evident that the prehistoric peoples set the example of that hippophagy which scarcity of animal food has again introduced into Europe. Now at least there are no wild horses on the continent, though they are mentioned as late as the 8th century in a letter of Pope Gregory to Boniface.[3] Horse-breeding is a highly important industry in almost all countries, and in several, as Russia, France, Hungary, and Spain, the state gives it exceptional support. Those which have the greatest export trade are Russia, Denmark, Austria-Hungary, Germany, the Netherlands, and Belgium. The Hungarians are a specially horse-loving people, counting in 1871 no fewer than 141 horses to the thousand inhabitants, instead of 67 as in Austria. Almost every district of the continent has a breed of its own: Russia reckons those of the Bashkirs, the Calmucks, the Don-Cossacks, the Esthonians, and the Finlanders as among its best; France sets store by those of Flanders, Picardy, Normandy, Limousin, and Auvergne; Germany by those of Hanover, Oldenburg, and Mecklenburg, which indeed rank among the most powerful in the world; and Great Britain by those of Suffolk and Clydesdale. The English racers are famous throughout the world, and Iceland and the Shetland Islands are well known for their hardy breed of diminutive ponies. The ass and the mule are most abundant in the southern parts of the continent, more especially in Spain and Italy. In the one country they number about 2,320,000, and in the other about 1,000,000. The camel is not popularly considered a European animal; but it is reared in Russia in the provinces of Orenburg, Astrakhan, and Taurid, in Turkey on the Lower Danube, and in Spain at Madrid and Cadiz; and it has even been introduced into Tuscany. One of the strangest sights of southern Russia to a traveller from the west is the huge ungainly creature yoked to what is practically a toy cart. A much more important beast of burden in eastern and southern Europe is the ox; the long lines of slow-moving wains in Roumania, for example, are not unlike what one would expect in Cape Colony. In western Europe it is mainly used for the plough or fattened for its flesh. The Netherlands, Denmark, Servia, Roumania, Turkey, Russia, Italy, Sweden, Spain, and Germany are all exporters of cattle; and all the other countries are more or less engaged in cattle-breeding for their own demands. It is estimated that there are about 100 distinct local varieties or breeds in Europe, and within the last hundred years an enormous advance has been made in the development and specialization of the finer types. The cows of Switzerland and of Guernsey may be taken as the two extremes in point of size, and the "Durhams" and "Devonshires" of England as examples of the results of human supervision and control. The Dutch breed ranks very high in the production of milk. The buffalo is frequent in the south of Europe, more especially in Transylvania and Italy; in the former country the number is about 58,000, and in the latter about 40,000. Great attention is given to dairy-farming in Great Britain,

France, Germany, Switzerland, Denmark, Austria, and part of Italy. Switzerland, the Netherlands, Austria, Denmark, Ireland, and Finland are exporters of cheese or butter, or both; Italy, though famous for the so-called Parmesan cheese, requires a large import, and the abundance of olive oil discourages the manufacture of butter. Sheep are of immense economic value to most European countries, and form an important article of export for the Netherlands, Germany, Austria, Hungary, Russia, Italy, Portugal, Denmark, Servia, Roumania, and Sweden. The local varieties are even more numerous than in the case of the horned cattle, and the development of remarkable breeds quite as wonderful. In all the more mountainous countries the goat is abundant, especially in Spain, Italy, and Germany. The swine is distributed throughout the whole continent, but in no district does it take so high a place as in Servia, where there are no fewer than 1062 to 1000 inhabitants, a proportion which more than doubles the next highest, which is afforded by Luxembourg. Spain ranks third in the list, and has a large export of hams and sausages. In the rearing and management of poultry France is the first country in Europe, and has consequently a large surplus of both fowls and eggs. The latter produce is also exported by Austria and Spain. In Pomerania, Brandenburg, West Prussia, Mecklenburg, and Würtemberg, the breeding of geese has become a great source of wealth, and the town of Strasburg is famous all the world over for its *pâtes des foiés gras.*

The following tables show the distribution of the more important domestic animals in the principal countries of Europe:—

	Year.	Horses.	To one sq. kilometre.	To one sq. mile.	To 1000 inhabitants.	Cattle.	To one sq. kilometre.	To one sq. mile.	To 1000 inhabitants.
Italy	1868	1,196,128	4·0	10·3	44·6	3,489,125	11·8	30·5	130·2

Races.

Ethnology is still in its infancy, painfully learning its first principles, and gradually discovering true methods of verifying its data and generalizing their teachings. There is such a thing as race; but we cannot be said to have attained to any single test or any combination of tests which does not leave our classifications more or less uncertain. We can ascertain whether the majority of a given people have dark hair or light, whether they are dolichocephalic, mesocephalic, or brachycephalic, or exhibit several varieties of skull; but it has still to be proved how far such characteristics are permanent, and as permanent available for our purpose. Europe in every square mile of its surface gives the lie to the supposition that consanguinity is implied by community of speech; Celts are equally eloquent in English and French; Slavonians equally enthusiastic for the dignity of Deutschland or the glory of Greece.[1] There are, perhaps, only two peoples in Europe of whom we can be said to have anything like ethnological statistics, the Jews and the Gypsies; and in both cases it is due to the fact that they have so long been treated as social or religious pariahs. It is easy to ascertain how many men in Europe use French as their mother-tongue; but we have no means, apart from historic evidence, which applies only to individual instances, of knowing whether three generations back any man's progenitor was a Corsican, a German, or a Breton. And if there is one fact to which every new investigation gives additional emphasis it is this, that there is no nationality, and no individual component of a nationality, which can establish the purity of its blood. What to the superficial observer are the most homogeneous peoples turn out on closer examination to be only conglomerates in which the elements are better assimilated. In Würtemberg, for example, as is shown by H. v. Hölder, the so-called German population is composed of Romans, Vindelicians, Rhætians, Avars, Hungarians, Slaves, Swiss, Swedes, and others introduced during the Thirty Years' War, Waldensians, Tyrolese, and Jews.[2] Still it is true (to borrow another analogy from geology), that if all are more or less obviously conglomerates, the materials have probably been derived for the most part from strata of the same formation. If the Frenchman is partly German, partly Celtic, German and Celt do not differ from each other more than limestone, marble, and chalk.

From recent researches it is now familiarly known that Europe had its human inhabitants in the Pleistocene period. They are distinguished by the name of the Palæolithic or Old Stone people, in contrast to a later population still in the same stage of civilization. Their remains have been discovered in England, Belgium, France, Germany, and Switzerland; and some investigators are disposed to recognize two varieties, distinguished as the men of the caves and the men of the river-beds.[1] Having possibly entered Europe before the first glacial period, they were certainly there at the final transition to the present conditions of climate. They lived by hunting and fishing, and in general characteristics appear to have been similar to the Eskimo, with whom some are disposed to identify them. If this identification be a mistake (and at best it is very problematical), they have left no distinct representatives behind them. What progress they had made in the arts, necessitated by their mode of life, may be in some measure estimated by the remarkable relics of their implements and weapons still recognizable; but there are no sufficient data to decide whether they were in a state of advance or decline: the difference of finish in different specimens of the same handiwork may be due to different degrees of care or skill possessed by contemporaneous workmen. As far as can be judged, the continent of Europe again ceased for a time to be a human habitation; and when light breaks in once more it is found in possession apparently of two races, both in the Stone stage of civilization, and known by the common name of the Neolithic or New Stone peoples. In the mean time the fauna of Europe had changed and become in the main what it still is. The chief point of interest attaching to these Neolithians is how far the brachycephalic, and presumably the older, variety is still traceable in our modern population.

---

[2] H. v. Hölder, *Zusammenstellung der in Württemberg vorkommenden Schädelformen*, 1876.

There are several peoples, most of them of small numerical importance, which are undoubtedly aliens from the commonwealth of the Aryan race now dominant throughout the greater part of the continent,—the Turks, the Magyars, the Finns, Esthonians, and Lapps, the Votiaks, and the Basques; and we know that in the Roman period of the historic epoch the Iberians, the Ligurians, and possibly the Etruscans and the Rhætians, occupied a similar position. The Turks and the Magyars are at once put out of the question by the fact that there is documentary evidence of their arrival in Europe long after the Christian era; and the dubiety which attaches to the affinity of the Etruscans and the Rhætians renders their classification impracticable. The Votiaks may be left out of account, from their almost Asiatic localization; so that there only remain four actual and two historical peoples to be considered. Three of the four—the Finns, Esthonians, and the Lapps,—may be bracketed together as Ugrians or Uralians, or under any other convenient name (though the Lapps may possibly be more distinct than this would make them), so that practically we have two actual and two historical. Arranged geographically, the Ugrians constitute a north-eastern or Baltic group; and the Basques, the Iberians, and the Ligurians a southern or Mediterranean group. Of the Ligurians little further is certainly known than that in historic times they occupied the north-western slopes of the Apennines, or the modern Piedmont, and extended west to the mouth of the Rhone; but probable traces of their presence have been collected as far south as the mouth of the Tiber and as far north as the Loire or Liger. Of their language we are absolutely ignorant, and their classification is almost purely hypothetical. They evidently lost ground at a very early period from the encroachments of various peoples, and among others from the inroads of the Iberians, whom we have now to consider. This people is specially connected with the Spanish peninsula, which derived from them the popular name of Iberia; but they appear also to have occupied Sardinia, Corsica, and Sicily, may possibly, as some maintain, have been one of the primitive elements of the population of Italy, and, according to a hint of Tacitus, probably extended as far north as Brittany. At the time of the Roman conquest of Spain they were already largely mingled with Celtic blood, a fact which was indicated by the name of Celtiberians. There is no reason to suppose that they have died out or been exterminated, and consequently it is presumably possible to discover them more or less distinctly among the mingled population of modern Spain. Here the Basques at once present themselves, a peculiar people speaking a peculiar language, and occupying the very part of the country where from analogy we might expect to find the remains of an ancient race. In what respect do the Basques agree with our knowledge about the Iberians? The Iberians, as has just been stated, were no longer homogeneous at the time of the Roman conquest; and the Basques, according to cranial data, exhibit an interfusion of blood: "they possess a moderate brachycephalism and a strongly marked dolichocephalism." The Iberians, however, were clearly distinguishable from the Celts; and the same is true of the Basques. The Iberians are described as of short stature, slight build, and dark complexion; and a similar account may be given of the Basques. The identification of the two peoples is consequently accepted by a large number of anthropologists; but the unanimity is hardly so great in regard to their further identification with the Ugrians of the north-east. In favor of the generalization, there is a certain similarity of physical type, and the probability, as it appears to a large school of investigators, that the Finns and Esthonians are, like the Basques, the remains of a population which formerly extended to the south and west over a much wider area; against the generalization is the fact that no closer connection lies between the Basque language and the Finnish than that they both belong to the agglutinative family, and it is quite as probable that the Ugrians have come in from the north and east at a comparatively modern period. If we adopt the bolder hypothesis in its full extent, and it is adopted by many investigators, the continent of Europe was originally inhabited by a small, swarthy, brachycephalic race, who were formerly represented in historic times by Iberians, Ligurians, and other less known peoples, and in modern times are still partially represented by the Basques, the Esthonians, and the Finns, who have retained their non-Aryan speech, and by smaller groups in England, Brittany, Prussia, and Spain, who have adopted the alien languages spoken in their vicinity. By some a still further identification is ventured with the Berbers of North Africa; and a few, as Hyde Clarke and Homalius d'Halloy, maintain that the so-called Aryan immigration was only in a comparatively small degree an introduction of a new race, and ought rather to be viewed as the diffusion of a civilization. Whatever dispute, however, such ethnological innovators may raise, there can be no question as to the almost universal predominance of the Aryan influences in the historic times; and though anything like chronology is for the most part out of the question, the general features of the great movement to which these influences are due can be stated with considerable certainty. Four great Aryan detachments are easily distinguished, and may for convenience be designated by the very imperfect and somewhat misleading names of the Græco-Latin or Southern, the Celtic or Central, the Teutonic or Northern, and the Slavonic or North-Eastern. Whether the Southern or the Celtic was the first of the two to enter Europe is altogether unknown: one offshoot from a common stock may easily maintain a nomadic or semi-nomadic state for a longer time than another and a later offshoot. The southern detachment was probably a succession of detachments,—the first represented, it may be, by the old progenitors of the Albanians and the so-called Pelasgic tribes, the second by the various tribes who settled in Italy, and the third by the Hellenic or Greek tribes. The Greeks at least appear to have entered Europe by way of Asia Minor and the Archipelago, and the Italian tribes may have followed a similar route. A more northern line of march, or nomadic progress, was chosen by the Celts, of whose passage up the valley of the Danube we have a trace in the Boii, the Celtic people who have given their name to the now Germanized kingdom of Bavaria. If the opinion of Virchow, based on the presumed incorporation of ancient historical materials in the *Ora Maritima* of Avienus, be correct, they reached southern Gaul and Spain about the 6th century B.C.[2] The Teutons or Germans began to be known to the Romans shortly before the Christian era, and in the 4th century A.D. pushed westward within the boundaries of the empire. The Slavonians have never advanced much beyond the Elbe in the north, but towards the south they extended in the course of the 9th and 10th centuries into Austria on the one hand and Greece on the other. Of the Semitic peoples, the Jews, which are now the most important, have entered in successive detachments, more in the fashion of ordinary immigrants; the Arabs, who contributed largely to the progress of European civilization, but have left little trace of their blood except in southern Spain, crossed into that country in 710. The settlement of the Hungarians dates from the 10th century, and that of the Ottoman Turks, the last great addition to the ethnological conglomerate of Europe, dates no further back than the 14th.

The following table, founded (as all such estimates are) mainly on linguistic and political data, is given by Dr. Brachelli as an approximate survey of the numerical importance of the various peoples of Europe. A strictly ethnographical classification will probably be always impossible, and certainly cannot be attained in the present state of scientific statistics. In many cases the possible error in the summation is very considerable: the Jews, for example, here given at 3,000,000, are reckoned at 5,226,858 in an interesting article in the *Journal of the Society of Biblical Archæology*, 1876,—2,647,036 of them being assigned to Russia.

	German peoples		94,980,000
	Germans, Dutch, and Flemish	58,100,000	
	English	28,800,000	
	Swedes, Norwegians, Danes, Icelanders	8,080,000	
	Greco-Latin peoples		96,410,000
	French and Walloons	37,000,000	
	Italians and Friulians	27,800,000	
	Spaniards and Portuguese	20,800,000	
	Roumanians, Moldavians, Wallachs	8,030,000	
	Greeks and Hellenized Wallachians	2,720,000	
	Rhætians or Ladinians	60,000	
	Slavonic peoples		82,170,000
North Slavs	Russians and Ruthenians	55,000,000	
	Poles	9,700,000	
	Bohemians, Moravians, Slovaks	6,500,000	
	Wends	140,000	
South Slavs	Croatians, Servians, Bosniaks	5,800,000	
	Bulgarians	3,800,000	
	Slovenians	1,230,000	
	Celts		4,100,000
	Semitic peoples		3,200,000
	Jews	3,000,000	
	Maltese, Moriscos, and Arabs	200,000	
	Lithuanians		2,800,000
	Albanians		1,300,000
	Basques		700,000
	Gypsies		600,000
	Circassians		400,000
	Armenians		260,000
	Total of Aryanized populations		286,920,000
	Magyars		5,920,000
	Finnish peoples		4,710,000
	Total of Uralian population		10,630,000
	Tatar peoples		2,500,000
	Osman Turks		1,200,000
	Kalmucks		100,000
	Total of Mongolians		3,800,000

Language.

Although language is no test of race, it is the best evidence for present or past community of social or political life; and nothing is better fitted to give a true impression of the position and relative importance of the peoples of Europe than a survey of their linguistic differences and affinities.[1] The following table contains the names of the various languages which are still spoken on the Continent, as well as of those which, though now extinct, can be clearly traced in other forms. Two asterisks are employed to mark those which are emphatically dead languages, while one indicates those which have a kind of artificial life in ecclesiastical or literary usage.

I. ARYAN (Indo-Germanic, Indo-European, Celto-Germanic).		
1. INDIC branch, represented by		Gypsy dialects.
2. IRANIC branch " "		(a) Ossetian.
		(b) Armenian.
3. HELLENIC branch, " "		*(a) Greek.
		(b) Romaic.
		(c) Neo-Hellenic.
4. ITALIC branch " "		*(a) Latin.
		**(b) Oscan.
		**(c) Umbrian, etc.
	Neo-Latin	(d) French.
		(e) Walloon.
		(f) Provençal.
		(g) Italian.
		(h) Ladin (Rumonsh, Rumansh, Rheto-Romance.)
		(i) Spanish.
		(j) Portuguese.
		(k) Roumanian.
5. CELTIC branch, represented by		(a) Irish.
		(b) Erse or Gaelic.
		(c) Manx.
		(d) Welsh.
		**(e) Cornish.
		(f) Low Breton.
6. TEUTONIC branch, represented by		**(a) Gothic.
	Scandinavian	**(b) Norse or Old Norse.
		(c) Icelandic and Faroese.
		(d) Norwegian.
		(e) Swedish.
		(f) Danish.
	Low German	**(g) Saxon, Anglo-Saxon, or First English.
		(h) English.
		**(i) Old Saxon.
		(j) Platt-Deutsch or Low German.
		(k) Flemish } Netherlandish.
		(l) Dutch } Netherlandish.
		(m) Frisic.
	High German	**(n) Old High German.
		(o) Middle High German.
		(p) New High or Literary German.
7. SLAVONIC branch, represented by		*(a) Church Slavonic.
	South-Eastern	(b) Russian.
		(c) Ruthenian, Rusniak, or Little Russian.
		(d) White Russian or Bielo-Russian.
		(e) Bulgarian.
		(f) Servo-Croatian.
		(g) Slovenian.
	Western	(h) Czech (Bohemian).
		(i) Slovakian.
		(j) Polish.
		(k) Sorbian (Wendic, Lusatian).
		*(l) Polabian.
8. LETTIC branch, represented by		**(a) Old Prussian.
		(b) Lettish.
		(c) Lithuanian.
9. UNATTACHED		**?(a) Old Dacian.
		(b) Albanian.
II. SEMITIC.		
1. CANAANITIC branch, represented by		*(a) Hebrew.
		**(b) Phœnician or Punic.
2. ARABIC branch, represented by		**(a) Arabic.
		**(b) Mosarabic.
		(c) Maltese.
III. FINNO-TATARIC (Turanian, Uralo-Altaic, etc.).		
1. SAMOYEDIC branch or group, represented by		(a) Yurak.
2. FINNIC or UGRIAN, represented by		(a) Finnish proper or Suonic.
		(b) Karelian.
		(c) Tchudic.
		(d) Vepsic.
		(e) Votick.
		(f) Crewinian.
		(g) Esthonian.
		(h) Livonian.
		(i) Lapponic.
		(j) Tcheremissian.
		(k) Mordvinian.
		(l) Permian.
		(m) Votiak.
		(n) Siryenian.
		(o) Magyar or Hungarian.
3. TURKISH or TATAR group, represented by		(a) Kazak Khirghiz.
		(b) Nogairic.
		(c) Tchuvak.
		(d) Turkish.
4. UNATTACHED		Basque.

From this conspectus it appears that there are still about 60 distinct languages spoken in Europe, without including Latin, Greek, Old Slavonic, and Hebrew, which are still used in literature or ecclesiastical liturgies. Besides, as we shall presently see, all those which are spoken over extensive territories, and some even which are confined within very narrow limits, are broken up into several distinct dialects. Most of the number, however, are destined to disappear within a comparatively short period, before the encroachments of the few which are especially favored by political circumstances and literary culture. The process is rapidly going on, and everything tends to its acceleration. Some, indeed, whose doom appeared almost sealed in the end of last century, have gathered fresh life and repulsed the intrusive language by which their existence was threatened; and on others a temporary and melancholy restoration has been inflicted by the mistaken enthusiasm of a patriotic minority. English, French, German, Russian, Italian, and Spanish will probably for a long time share the real dominion of Europe; Dutch and the Scandinavian tongues will maintain their ground, but they hardly give promise of expansion; Bohemian, Hungarian, and the South-Slavonic have made good their position; and Neo-Hellenic, under favoring circumstances, may get possession of the territory of its nobler ancestor.

---

[1] See on the whole subject Hovelacque's *Science of Language*, Latham's *Nationalities of Europe*, and the same author's *Philology*.

Greek and Latin may fairly claim the first place in an historic sketch, on account of the immense and varied influence they have exerted, directly or indirectly, on the popular and literary language of all the prominent peoples of Europe. The former, which is preserved in what is at once the most perfect and the most multiform of the older literatures of the world, was spoken wherever a Greek city was established in Asia, Europe, or Africa. It had several well-marked phonetic dialects:—the Æolic, represented in Europe by the Bœotian variety; the Doric, employed in Sparta and most of the other Peloponnesian states, as well as in other colonies of Sicily and Southern Italy; and the Ionic, which in the Attic dialect attained its noblest development, and became the principal literary form. A rude dialect of the Æolian type was spoken in Thessaly; and in several districts of northern Greece other varieties must have had their home, some of them probably so divergent from the more cultured dialects as to be unrecognizable by the rough and ready philology of the ancient Greeks. After the extension of the political power of the Hellenic race by the Hellenized Macedonians the Attic dialect became in a necessarily modified guise the language of at least the educated classes over a wide foreign area. This κοινὴ διάλεκτος, or common dialect as it was called, was that in which all the Christian Scriptures were, if not originally penned, at least most potently disseminated; and some time after the establishment of the seat of the empire at Constantinople it was adopted as the official language of Eastern Europe, and developed or degenerated into what is distinguished as Byzantine Greek. Amid all the linguistic confusion of mediæval and modern times in the Balkan peninsula the old Hellenic speech maintained a precarious and degraded life in the so-called Romaic of the Greek people, still recognizable to the philologist, but to the vulgar ear and eye very successfully disguised. It is still spoken, not only in the modern kingdom of Greece, but in Thessaly and other parts of Turkey along the coasts of the Ægean and the Sea of Marmora, and in the Greek settlements of southern Russia. Since the declaration of national independence an attempt has been made to go back to something liker the language of Xenophon; but as yet the Neo-Hellenic is almost purely a literary form, unintelligible to the great bulk of the people in the country. At best it is only a compromise between ancient Greek and Romaic, neither conforming to the classical standard of the one nor systematically accepting the grammatical changes developed in the other. As education advances,—and it is advancing rapidly under the control of the central administration,—it will probably take root among the people, and under the vivifying influences of national life grow up into a national speech. The ancient common dialect is still used in the liturgical services of the Oriental Church. The alphabet has been employed by several communities in the Turkish empire for their Turkish dialects,—among others by the people of Mariupol.[1]

Latin was only one of a number of closely related languages domiciled in the peninsula of the Apennines, and by several of these it was affected much in the same way in which English is affected by German or French. Most of the number have left neither literature nor history behind them, but they must still be differentiating factors in the dialects of modern Italy. Oscan, which was spoken in a large part of the country south of Rome, and Umbrian, which takes its name from a district to the north, are both known to us from inscriptions,—the latter by the remarkable liturgical series called the Eugubine Tables. The Latin language kept pace with the extension of the Roman empire till it came into contact with the higher culture of Greece and the East; as an aggressive language it has no historic parallel, for though the area of English has advanced as rapidly in modern times, this advance has mainly found place where English-speaking people have outnumbered the foreign elements in the population. It continued to be the language of nearly all European literature for centuries after it had ceased to be a spoken speech; and it was the language of all learned literature well on in the 17th century. It is still used in the liturgy of the Roman Catholic Church, and still forms the most potent linguistic element in all European education. Its alphabet is more widely employed than any other in Europe, and is at the present moment gaining ground against the "Gothic" characters of modern Germany, as it did in early ages against the Saxon characters in England.

Of the languages which have sprung from Latin, French resembles it most in its fortunes, though not in its forms. It is the official, literary, and educational language of the country whose name it bears, and is daily becoming more and more the popular language as well. Based as it is on the old *langue d'œil* of the north, it has gained the superiority over the dialects of Burgundy, Picardy, and Normandy, and the more cultured Provençal of the south, has already reduced them to the rank of mere patois, and is gradually diminishing even their local importance. On the north-west it is more slowly displacing the Breton, and in the south making inroads on the Basque. It was nearly naturalized among a large part of the inhabitants of Alsace-Lorraine, and is still spoken by upwards of 200,000 of the new citizens of the German empire. In Switzerland it is the mother tongue of about 600,000 people, being dominant in Neufchatel, Geneva, and Vaud, and sharing the ground with German in Freiburg, Valais, and Bern. In Belgium it is the principal speech of the educated classes. No European language has had such an extensive foreign history within the continent. Not only was the closely related Norman French introduced into England in the 11th century, with such striking effect on the English vocabulary, but at several subsequent periods literary French has been potently at work. In the decadent period of German literature it largely supplemented the German language among the upper classes, and for a time furnished a large proportion of his vocabulary to the nominal writer of German. In Russia there was a similar French period about the beginning of the 18th century, which has left its influence to this day on the official publications of the Government. And in spite of the growing claims of German and English, French is still acquired by a greater number of foreigners than any other modern tongue.

The language usually known as Italian is not so much the national language of Italy as the language of a special district. The other dialects have not sunk to the level of patois; and at the present moment it is a matter of keen debate what is to be considered the true standard for the people at large. From Venice to Palermo there is a rich variety of forms which have received more or less of literary culture: and the pretensions of Florence to be the sole and final arbitress are far from being unanimously admitted. Whatever position be assigned to Tuscan as the language of education, it will be a long time before it attain the predominance in Italy which French possesses in France. The dialects are usually divided into three main groups:—those of Upper Italy, including Genoese, Piedmontese, Venetian, Æmilian, and Lombard; those of Central Italy, including Tuscan, Roman, and Corsican; those of Southern Italy, including Neapolitan, Calabrian, Sicilian, and Sardinian. From Italian the other peoples of Europe have borrowed many terms for artistic technicalities, but comparatively little which belongs to everyday life.

Literary Spanish or Castilian is in much the same position as literary Italian, with this difference, that its literary precedence is more definitely established. A large area is still occupied by Catalonian or Catalan, both in Catalonia proper, in Valencia, and in Majorca; and the speech of the Galicians is much more akin to Portuguese. In Catalonia rich and poor, citizens and peasants, speak the provincial language; in Valencia and Majorca only the cultivated classes employ Castilian. On the whole, however, the Castilian territory is on the increase, and it is making its most rapid acquisitions from the Galician and Basque.[2] Spanish is naturally distinguished from the other Neo-Latin languages by the greater number of words which it has borrowed from Arabic.

Portuguese is really what the name implies, and has to contend against no alien idioms. In comparison with Spanish it has diverged further from the Latin type. It has been equally indebted to Arabic, and has also a considerable French element.

Walloon, the language spoken by the Latinized people of the Low Countries, is now a mere patois. Ladin is spoken by about 580,000 persons who occupy several considerable areas in the Alpine region, from the valley of the Rhine in the west to the neighborhood of Aquileia on the Adriatic in the east.[3] Roumanian is not only the national language of the country of that name, but is used by a considerable population in Servia, Hungary, Transylvania, Bukovina, Bessarabia, Roumelia, Thessaly, and Albania. In Roumania it is the object of increasing literary culture; and in spite of the foreign influences to which it has been so long exposed, it does not present much variety of dialect in the other districts.

Of the Teutonic languages the Gothic furnishes the oldest literary monument—the translation of the Scriptures by Ulphilas or Wulfila, who flourished in the latter part of the 4th century; but it is totally extinct, and among the living representatives of the branch the first place is due to what is popularly known as German *par excellence*,—that is, the modern literary or cultured form of High German. This is usually dated from Luther's translation of the Bible, which marks the transition from the "Middle" to the "New" period. It is not only the recognized speech of the various states of the German empire, but either in its cultured shape or in tributary dialects it is spoken by about 9,000,000 people in Austria-Hungary, and by nearly 2,000,000 in Switzerland. It has lost ground through the revival of Bohemian and Hungarian, but has gained on all the minor linguistic enclaves. Along the frontier regions of Russia and Poland it is partially retreating, partially advancing: Russia naturally discourages the German element in the Baltic provinces, and Germany as naturally the Polish element in Prussia. In both districts, German is the language of higher education. Whatever repressive measures Russia may adopt, it can plead, not only the example of Germany, but the fact that it is only attempting to recover ground that has been lost by the Slavonic tongues. Slavonic names of places occur as far west as Hanover, though the Germans frequently disguise or destroy them. Where it meets the Italian frontier the Teutonic language is retrogressive. Botzen in the end of last century was a border town of the German area; it is now thoroughly Italianized; and even Meran, several miles up the valley of the Adige, and 60 miles from the political frontier, is rapidly losing its Teutonic character. That the movement has been in this direction for centuries is clear: but it is doubtful whether the present German enclaves of the Sette Communi and Tredici Communi were always insular, or are to be taken as proof that the Teutonic frontier formerly extended as far south as the neighborhood of Verona and Vicenza.[1]

The territorial relations of the Scandinavian languages are sufficiently indicated by their names. They are nowhere aggressive, except where they come into contact with Finnish and Lapp. All of them, even the Faroese, have a certain amount of literature; but three only, Danish, Swedish, and Icelandic, are vigorously cultivated. Norway is mainly indebted for its books to Sweden and Denmark, and its language is slowly passing into a patois. Danish has undergone the greatest changes from the old Norse type, and naturally from its position has been most affected by foreign influences.

Of the Low German group the Old Saxon, formerly spoken between the Rhine and the Elbe, has left several remarkable literary monuments; and two or three of its dialects, now bracketed together as Anglo-Saxon, furnished the basis of the present English language, which, however, by its mere vocabulary has nearly as much right to be considered a member of the Latin or Italic branch. The only modern representative of the group besides English which ranks as a literary language is Dutch, which is spoken in Holland, and, under a slightly modified form known as Flemish, in a large part of Belgium. Along the coast and islands of the North Sea the current dialects, varying from district to district in an almost exceptional manner, are remnants of the old Frisian tongue, whose oldest written documents date from the 13th century; and the popular language of the countries between the Rhine and Weser and the Weser and Elbe, where it is not Dutch or Frisian, is Platt-Deutsch, which, while overshadowed by the High German, has recently attained a certain literary position through the writings of Fritz Reuter.

The Celtic languages are all without exception decadent,—the most tenacious of life being the Welsh and the Breton. The people who still retain them as their mother tongues are becoming more and more accustomed to the simultaneous use of the dominant languages around. The Welshman and the Scottish Highlander learn English, the Breton French. Cornish died out last century, and left only a few fragmentary texts; Irish is rapidly following it, but will be preserved in a considerable literature; Welsh alone has a fairly vigorous literature at the present time.

According to Professor Zerffi, there are no less than seventeen Slavonic dialects. The most important is Russian, or Great Russian, the national speech of the empire whose name it bears. At present it is spoken by about 34,390,000 of the 65,705,000 of the total population; and its area is rapidly being extended by the direct agency of the Government. In 1871 it was made the official language of Poland, and rendered obligatory in all the law courts of the country; and in 1876 it became practically the only permissible form in Little Russia, where all popular literature and public notices in the local language were prohibited. While it retains a rich inflexional system, Russian has enriched its vocabulary by a large foreign element, from French, English, and German; and its scientific terms are for the most part those of Western Europe. As a written language it is deeply indebted to the Church Slavonic. Closely cognate is the Little Russian, or Ruthenian, already mentioned, which is spoken by about 14,201,280 people in Russia and upwards of 3,000,000 in Austria. Its Russian area includes Volhynia, Podolia, Kieff, Kherson, Ekaterinoslaff, Kharkoff, Poltava, Tchernigoff, Minsk, Grodno, and Lublin, as well as portions of Astrakhan, the Don Cossack Country, Saratoff, and Voronezh; in Austria it is mainly confined to Galicia. Possessing as it does a rich store of popular tales and songs, and employed by several writers of great ability during the present century, it ranks much higher than the third Russian dialect—the White Russian—which is the current speech of about 3,592,000 people, for the most part in Grodno, Minsk, Mohileff, Vilna, and Vitebsk, and is mainly distinguished by Lithuanian and Polish elements. The second place in the Slavonic group may be assigned to Polish, which in spite of political disasters is still spoken by a large but scattered population. It is estimated that there are 3,905,871 Poles in Russian Poland, 2,450,000 in Prussia, 2,465,000 in Austria-Hungary, and 861,000 in European Russia. An extensive and vigorous literature will preserve the language even if it pass, as seems not improbable, altogether from the lips of men. Czech, or Tsekh, is the national language of Bohemia, and is also largely spoken in Moravia and north-western Hungary, where it is usually known by the names of Moravian and Slovak. The differences between the dialects of the several countries are on the whole comparatively slight; but as between Bohemian proper and Slovak, they are sufficiently marked to lead some philologists to recognize the Slovak as a separate language. There is a rich Bohemian literature which, dating from the 10th century, has after a long period of depression and threatened extinction received a new development in modern times. Bulgarian is distributed throughout European Turkey far beyond the district that bears the name of Bulgaria, and it also appears in eastern Roumania and south-western Russia. A very small proportion of the people by whom it is used are of Slavonic blood; and it has departed more than any other Slavonic language from the common type. Its literature is almost exclusively modern, and would be of little moment were it not for its possible value to a possible nation. A much higher position has been attained by the Servo-Croatian, which is spoken by about 5,500,000 people, in Servia, Bosnia, Montenegro, southern Hungary, Slavonia, Croatia, Istria, and Dalmatia. Its dialects though numerous are so slightly differentiated that with any one of them a traveller can make himself understood by those accustomed to any other. It is usual to divide them into three groups—a western or Istrian, a southern or Dalmatian, and an eastern or Servian. Even if the political unification of the South Slavonians should never be realized, the future of the Servo-Croatian is secured by the vigorous literary development which is encouraged both at Agram and Belgrade. Unfortunately it is written and printed in two alphabets—the Cyrillian being employed by the Servians and the Latin by the Croatians. The remaining Slavonic tongues are of little practical importance except to the philologist. The Wends are being rapidly Germanized, and are now estimated at about 137,000, principally situated within an area of rudely elliptical form, with its two foci represented by Bautzen and Kottbus. Since 1849 their numbers have diminished by upwards of 4200. The language shows two distinct varieties.[2]

The Lettic branch though decadent is interesting as linguistically the oldest of the Aryan languages in Europe. The Lithuanians were in the Middle Ages one of the most powerful peoples of the Baltic region, but fell into a secondary place by the incorporation of their country with Poland in 1386. Their language is still retained by about 150,000 or 200,000 people in Germany, and by about 1,434,750 in Russia, where those of the western part of the government of Kovno and the southern part of the government of Suwalki are known as Shomudes or Samogitians. Two dialects are recognized—the High or Southern, and the Low or Northern. The Letts still number more than 1,000,000, situated in Courland, Livonia, and Vitebsk. Old Prussian, extinct two hundred years ago, was very similar to Lithuanian. With regard to the two languages marked in the table as "unattached," almost nothing is known of Old Dacian, and the history of Albanian is but partially elucidated. The Skipitars, Arnauts, or Albanians are one of the most remarkable peoples of south-eastern Europe. They not only occupy Albania proper, but also appear in considerable numbers throughout the rest of European Turkey and Greece,—forming, it is calculated, a total of 1,500,000. The colonies which settled in Italy and Sicily, though amounting to nearly 90,000, have given up their native language. Hahn, who was the first to make a thorough investigation of the subject, distinguishes two dialects—the Toskan and the Gegian,—which are as distinct as High German and Platt-Deutsch. Besides the Greek alphabet another of dubious origin is also employed.[3]

The Semitic languages are mere exotics in modern Europe. Hebrew, the most widely distributed, is little more than the ecclesiastical language of the Jews, who for the most part employ the common language of the country in which they reside not only in public intercourse but also in private. At the same time it is regularly taught in their schools, furnishes them with a number of familiar every-day expressions, and is not only the language of the professional literature of theologians, but appears in frequent quotations in their popular periodicals. Arabic, at one time the dominant language not only of southern Spain but of Sicily and part of Italy, is nowhere the usual speech of any European community; but it is familiar to the educated classes of Turkey. Maltese can still be recognized as of Arabic derivation, but has incorporated a vast mass of foreign words. Mosarabic has been extinct at least since the 18th century; the liturgical service in the cathedral of Toledo, which still bears the name, is performed in Latin.

The most important of the Finno-Tataric languages are the Turkish, the Hungarian, and the Finnish. The first varies greatly in its vocabulary in different places and grades of society; and the official form is largely composed of Arabic words. As a popular speech in Europe it has a very limited and discontinuous area. Hungarian, on the other hand, has maintained or recovered a remarkable degree of homogeneousness, and occupies on the whole a very compact territory in spite of the intrusion of German; while its literature ranks as one of the most vigorous of the secondary literatures of Europe. Finnish proper is spoken by 1,710,274 people in the Russian empire (of whom 1,615,613 are in the duchy of Finland), and by 14,930 in Sweden and 7637 in Norway; while the closely cognate Karelian numbers 303,277 in Russia. The Tchudes, Vepses, and Votes, who amount to 48,000 in all, live in the governments of Olonetz, Vologda, Novgorod, and St. Petersburg, in the neighborhood of Lakes Ladoga and Onega. Their languages or dialects are very similar to Esthonian, which, with the exception of Hungarian, ranks as the most literary member of the group, and is spoken by upwards of 749,000 people. Livonian lingers as the speech of a few thousand seafaring folk in Courland. The Lapps contribute 17,178 to the population of Norway, 6700 to that of Sweden, and 7497 to that of Russia. Their language is divided into four dialects. The Tcheremisses, Mordwines, and Votiaks are grouped together as Finns of the Volga,—the first, to the number of about 260,000, situated in the country between the rivers Viatka and Vetluga; the second being scattered, to the number of about 792,000, through the governments of Samara, Saratoff, Simbirsk, Pensa, Nizhni-Novgorod, Tamboff, Kazan, Ufa, Orenburg, and Astrakhan; and the third, about 240,500 strong, occupying the western half of the government of Viatka. Another group is composed of the Permians, Siryenians, and Voguls. The two former were at one time one people, and had considerable fame in the Middle Ages for their commercial activity; they are now mere hunters, fishers, and peddlers, and number respectively about 67,000 and 85,400 people in Perm, Vologda, and Archangel. The Voguls are a little colony from Asia, 2000 strong, in the government of Perm. The total number of Tatars in Russia is said to be 1,212,610. They are found in all the sixty-one governments, with the exception of nine; but are most numerous in Kazan, Simbirsk, Ufa, and Viatka. They are closely connected with the Bashkirs of Ufa, Orenburg, Perm, and Viatka, who altogether amount to 757,000. The Nogaians, who live in the neighborhood of the Sea of Azoff, are a mixed people, containing remnants of the Khazars, Petchenegs, and Cumanians; the Tchuvashes are a Tatarized branch of the Finns of the Volga; and the Meshtcheryaks of Ufa, Orenburg, Pensa, and Kazan are also of Finnish descent. The first still number 15,000, though a large number emigrated to Turkey after the Crimean war, the second 569,000, the third 136,000. The language of the Nogaians is the same with that of the Tatars proper, and that of the Tchuvashes seems to lie midway between Nogairic and Turkish. The Kirghiz, of whom there are 156,000 in Astrakhan and Orenburg, speak a dialect which is equally difficult of comprehension to the Tatar of Kazan and the Bashkir; and the Calmucks—107,000 in Astrakhan—are still more widely separated by language from their nearest kin.[1]

Basque, which is spoken in the Pyrenean districts of France and Spain, is an agglutinative language, but cannot be classified. It is dying out more rapidly in the Spanish than in the French territory.[2]

Political divisions.

In 1877, as appears by the table on page 617, the European territory was distributed among 18 distinct political totalities (exclusive of the petty states of San Marino, Andorra, Monaco, and Luxembourg), viz.—the German empire, the Russian empire, the Ottoman empire, the united monarchy of Austria-Hungary, the united kingdom of Great Britain and Ireland, the republic of France, the kingdoms of Italy, Spain, and Portugal, the kingdoms of Belgium and of the Netherlands, the kingdom of Denmark, the united monarchy of Norway and Sweden, the kingdom of Greece, the republican confederation of Switzerland, and the principalities of Montenegro, Servia, and Roumania. Several of these consist of a greater or smaller number of partially independent states connected with each other according to very different degrees of political copartnery. The German empire, as one of the most recent as well as most extensive, naturally presents an unusual number of anomalies. Founded April 16, 1871, it comprises no fewer than twenty-six states under the presidency of the kingdom of Prussia, and these states are very dissimilar in size, constitution, rank, and general importance. Four, including Prussia, are kingdoms, six are grand duchies, five are duchies, seven are principalities, and three are free cities. The organization by which they are united consists mainly of a federal council or *Bundesrath*, in which the individual states are represented by the nominees of their several governments, and a *Reichstag*, or Imperial Diet, the members of which are elected by universal suffrage. All military power is centralized in the hands of the emperor: his consent is necessary for all important appointments in the different divisions of the army, and he can command the erection of fortresses on the soil of any of the states, and if occasion requires can declare any part in a condition of siege. The practical dominancy of Prussia is further secured by the fact that it possesses 236 of the 397 members who compose the Imperial Diet. As separate states, Prussia, Würtemberg, Saxony, and Bavaria are all constitutional monarchies, each with its parliament or *Landstag*, consisting of an upper and a lower house. The various grand-duchies, duchies, and principalities have their several *Stände*, or states, some consisting of two chambers and some of one, and presenting considerable variety in the amount of representation accorded to different elements of the community, in the rules of election, and in the length of period for which it is valid. That unusual combination of geographical names, Austria-Hungary, and its equally unusual adjective Austrian-Hungarian, which are so uncouth and bewildering to the ordinary reader, are an attempt to indicate the relation of complete political equality established between the two great sections of what is popularly known as the Austrian empire. Each has its own parliament,—in Austria called the *Reichsrath* or Imperial Council, and in Hungary the *Reichstag* or Imperial Diet; each its own ministers, budget, and other administrative machinery; and the transactions between the two countries not unfrequently show like the transactions between two independent powers. The same person is monarch over both, and the united army is under his command, but there practically the unification ceases. Russia is an hereditary monarchy, nominally governed by the absolute will of the emperor or czar, but really by this in combination with a system of four great councils. Finland still retains its separate parliament, instituted in 1772, and supplemented by an imperial senate under the presidency of a governor-general. Switzerland is a confederation of twenty-two states, with a republican government. The supreme legislative power is in the hands of the federal assembly, which is composed of a national council or *Nationalrath*, and a council of states or *Ständerath*,—the members of the former being chosen by the people of Switzerland in general, and the members of the latter by the people of the individual cantons. The executive power is entrusted to a federal council, and the highest judicial authority to a federal tribunal, consisting respectively of seven and eleven members, nominated for three and six years by the federal assembly. Sweden and Norway are two kingdoms under one king, with separate government, constitution, and laws. In Sweden the legislative power is mainly in the hands of the diet, which consists of two elective chambers, while the executive is in the hands of the king and a council of state. The constitution of Norway is rather more democratic: the full legislative power belongs to the Storthing, and the king has no right of veto if the same bill passes three times. The common affairs of the two countries are decided in a council of state consisting of representatives of each.

Such are the most abnormal political arrangements in Europe. Britain, Belgium, Denmark, Italy, the Netherlands, Portugal, Spain, Roumania, Servia, are hereditary monarchies, with a parliament of two chambers and a responsible ministry. Greece differs in as far as it has only one chamber. Montenegro is an hereditary monarchy, with a senate; Monaco an hereditary principality, with a council of state; and Andorra and San Marino are both republics, with a general council.

Population.

It may be safely affirmed that the population of Europe has been steadily increasing since the time of the great Revolution, though it is impossible to ascertain exactly the average rate. The number in 1787 is said to have been 144,000,000; at the peace of 1815, 180,000,000; in 1833, according to Balbi, 227,000,000; in 1854, 258,778,850; and in 1874, according to Behm and Wagner, 309,178,300. If the earlier estimates, which are little better than guesses, even approximate to the truth, we would have in 59 years an average annual increase of 1,850,000. In England and Prussia rather more than one per cent. of increase takes place every year, while in France during the greater part of the century the gain has been

[1] Including 14·23 German, or 302·57 English square miles of islands not given in the separate kingdoms.

considerably less, and in exceptional years there has even been a decrease. If then we adopt one per cent. as the mean for Europe, the 180,000,000 people in Europe ought, in 1874, to be represented by 323,769,000. Two causes have greatly diminished the growth—war and emigration. In the Crimean war the direct loss was 386,000 soldiers; that of the French army in Italy was 10,173; and that of the German army in 1866 between 10,000 and 11,000. In the war of 1871–72 the victors lost 45,000 and the conquered a still greater number. The total loss since 1855 cannot be less than a million at the very least. Of the extent to which emigration from Europe has gone on during the present century every one has some idea; the immense territory occupied by people of European descent speaks for itself. Since 1820, Germany has contributed about two million inhabitants to the United States alone; since 1815, Great Britain and Ireland have seen no less than from eight to nine millions of their populations leave their shores for ever. The drain on other countries, however, has been much less,—France, for example, counting her loss by emigration in the ten years from 1849 to 1858 as 200,000, and Austria her loss from 1850 to 1868 at no more than 58,000.

The general rule that, other conditions being equal, the population decreases with the elevation of the country, holds especially true of Europe. None of its larger cities lie far above the sea-level. The highest point of permanent human occupation is the hospice of St. Bernard—at an altitude of 2472 metres, or 8108 feet; and the highest village, St. Veron la Ville, in the neighborhood of Briançon, has an altitude of 2009 metres, or 6589 feet. There is a little hamlet of German immigrants called Juf, 108 feet higher, in the Swiss valley of the Avers, a tributary of the Rhine. Chaux de Fonds, a town of nearly 20,000 inhabitants in the Jura, stands at an altitude of 1000 metres, or 3280 feet, and the average elevation of the Engadine, with its numerous villages, is about 6000 feet. The highest inhabited spot in the Dovre-Fjeld is said to be Hjerkin, at 3152 feet above the sea; in the Grampians Corrour (Inverness-shire) at 1738, in the Harz the Brockenhaus at 3739, and in the Pyrenees Mont Louis at 5208.[1]

The districts of densest population, or nearly 400 to the square mile, are the lower valley of the Thames, the neighborhood of Newcastle, and the area which includes Liverpool, Birmingham, Sheffield, and Leeds, in England, the district between Boulogne and Liége, the neighborhood of Cologne and Elberfeld-Barmen, the valley of the Rhine for some distance above the junction of the Maine, part of the valley of the Neckar, the country to the south of Leipsic, the vicinity of Prague, a large portion of the valley of the Po, especially round about Milan, the neighborhood of Naples, and a little district round about Oporto. Most of these districts of densest population are surrounded by areas in which the ratio varies from 280 to 380 inhabitants per square mile. In France the only districts approaching the higher figure are the vicinity of Paris and of Lyons; and in Spain the only spot reaching the lower is San Sebastian. Round about Barcelona and on the coast between Cartagena and the mouth of the Jucar there are from 190 to 240 per square mile. In no part of the Russian territory does the ratio rise higher than 140, and most of it varies from 25 to 95. The same low figures are applicable to the whole Scandinavian peninsula, with the exception of the most southern part of Sweden, which, with eastern Denmark, attains a ratio of 150 per square mile.[2] In a large part of Norway indeed, as well as in both the north and the south-east of Russia, the ratio is not more than from 3 to 5. The only other portions of the globe which reach the highest European density are the valley of the Ganges, part of the Chinese empire, and possibly some parts of central Africa.

Proportions of the sexes.

The numerical relation between the sexes is different in different countries as well as in the differently constituted portions of the same national community. The most prominent causes that interfere with the equilibrium are the greater destruction of men in time of war, and the greater removal of men by emigration. The following table gives the relations in the principal countries:—

	Males.	Females.	Excess or Defect of Females.
Russia, 1867	34,210,210	35,154,331	+ 944,121
German Empire, 1871	20,154,109	20,906,737	+ 752,628
Prussia, 1871	12,169,274	12,523,807	+ 354,533
Bavaria, 1871	2,368,558	2,494,892	+ 126,334
Saxony, 1871	1,248,799	1,307,445	+ 58,646
Würtemberg, 1871	876,164	942,375	+ 66,211
Baden, 1871	712,551	749,011	+ 36,460
Hesse, 1871	421,849	431,045	+ 9,196
Mecklenburg, 1871	319,096	335,783	+ 16,687
Hanse Towns, 1871	249,685	263,849	+ 14,164
Oldenburg, 1871	155,336	159,123	+ 3,787
Brunswick, 1871	155,540	156,630	+ 1,090
Anhalt, 1871	103,579	99,858	+ 3,721
Lippean States, Waldeck, and Pyrmont, 1871	96,927	102,491	+ 5,564
France, 1872	17,982,511	18,120,410	+ 137,899
Austria-Hungary, 1869	17,737,175	18,167,260	+ 430,085
Austrian portion	9,991,487	10,403,493	+ 412,066
Hungarian division	7,745,688	7,763,767	+ 18,079
Great Britain, 1871	15,584,132	16,261,247	+ 677,115
Italy, 1871	13,472,262	13,328,892	— 143,370
Spain, 1871	8,324,000	8,475,000	+ 151,000
Belgium, 1866	2,419,639	2,408,194	— 11,445
Roumania, 1860	2,276,558	2,148,403	— 128,555
Portugal, 1864	2,005,540	2,182,870	+ 177,336
Sweden, 1870	2,016,653	2,151,872	+ 135,219
Netherlands, 1869	1,764,118	1,815,411	+ 51,293
Switzerland, 1870	1,364,814	1,304,833	— 59,981
Denmark, 1870	918,788	945,708	+ 26,820
Finland, 1865	878,537	923,711	+ 45,174
Norway, 1865	835,947	865,809	+ 29,862
Greece, 1870	754,176	703,718	— 50,458
Servia, 1866	626,681	589,444	— 37,237
Luxembourg, 1871	98,245	99,283	+ 1,038

Portugal and Greece represent the two extremes—the former having far above the normal number of females, or 1088 to every 1000 males, and the latter far above the normal of males, or nearly 1072 to every 1000 females. The following table gives the order of the various countries:—

	Females to 1000 Males.		Females to 1000 Males.
Portugal	1088	Denmark	1030
Würtemberg	1076	Prussia	1029
Sweden	1067	Russia	1028
Lippe states	1057	Oldenburg	1027
Hanse Towns	1056	Austria-Hungary	1024
Bavaria	1053	Hesse	1022
Mecklenburg	1052	Spain	1018
Baden	1052	Luxembourg	1011
Finland	1051	France.	1008
Saxony	1047	Brunswick	1007
Switzerland	1046	Hungarian lands	1002
Great Britain	1043	Belgium	995
Austrian lands	1041	Italy	989
German empire	1037	Roumania	944
Anhalt	1037	Servia	940
Norway	1036	Greece	933
Netherlands	1030		

For Russia proper the census of 1858 gave 33,655,824 males to 35,275,904 females, or 1000 to 1048.

Population of cities.

During the present century the industrial development of the more advanced countries has led to a remarkable aggregation of the people into cities, and facilities of travel have in many cases caused a large part of the city population to take up their residence in suburbs more or less separate from the central nucleus. In the following list of the towns and cities in Europe with more than 100,000 inhabitants, it is noticeable that no fewer than twenty-one belong to Britain, and that nine of these are among the thirty, most of which are or have been political capitals, whose inhabitants exceed 200,000.

75.	Adrianople	(1874),	100,000

There are nine with 90,000 or upwards—Leghorn, the Hague, Malaga, Stuttgart, Frankfort-on-the-Maine, Jassy in Roumania, Sarratoff, La Valette in Malta, and Saloniki or Thessalonica; sixteen have more than 80,000—Oporto, Dantzic, Aberdeen, Murcia, Lemberg, Le Havre, Nottingham, Strasburg, Preston, Catania, Nuremberg, Bremen, Bolton, Gratz, Norwich, and Christiania; eighteen lie between 80,000 and 70,000—Wilna, Kieff, Kazan, Cork, Blackburn, Stettin, Roubaix, Barmen, Aix-la-Chapelle, Altona, Brünn, Ferrara, Rheims, Cadiz, Elberfeld, Trieste, Huddersfield, and Szegedin; twenty-one are upwards of 60,000—Düsseldorf, Toulon, Plymouth, Wolverhampton, Chemnitz, Lucca, Geneva, Saragossa, Granada, Verona, Brest, Padua, Halifax, Devonport, Amiens, Rochdale, Utrecht, Nismes, Versailles, Gothenburg, Nikolaieff; thirty-six between 50,000 and 60,000—Greenock, Brunswick, Montpellier, Tula, Krefeld, Alessandria, Swansea, Zurich, Modena, Posen, Maria-Theresiopol, Croydon, Limoges, Carthagena, Mainz, Southampton, Palma, Stockport, Mülhausen, Nancy, Halle, Berdicheff, Bath, Nice, Jerez de la Frontera, Rennes, Merthyr Tydvil, Essen, Metz, Augsburg, Reggio, Bari, Pisa, Seraievo, Gallipoli, Philippopel.

It must of course be kept in mind that lists like the above can only present an approximate view of the facts,—first, because the censuses or estimates of the various places are not strictly contemporaneous and do not proceed on the same methods; and, secondly, because the areas to which they apply are determined by different considerations in different cases. It is not unfrequently hard to say what ought to be accepted as the limits between town and not-town,—whether ancient villages and hamlets to which the city has grown outwards, or the modern suburbs which it has built at short distances, should be included or excluded. With those cities which have kept the characteristics of the walled towns of the mediæval period the matter is easily settled, but in most cases the modern city has either got rid of its walls and turned their site into promenades or boulevards, or, retaining them as an interesting historical monument, has overflowed their limits in all available directions. In some very modern instances, such as Elberfeld-Barmen in Prussia, clusters of dwelling-houses and industrial establishments have sprung up sporadically along a convenient valley; and while there are large gaps in what we may call the area of architectural occupation, the various groups have a complete community of social and commercial life. Municipal boundaries give us but little assistance, for these are modified not only by the different municipal systems of the different countries, but also by all kinds of local conveniences, traditions, and rivalries.

Military and naval forces.

An enormous increase has taken place since the French Revolution, and indeed within a much shorter period, in the size of the military establishments throughout Europe. The rivalries and jealousies of the various nations have led them to vie with each other in the strength of their armies and navies; and as it is impossible to withdraw more than a certain number of men from productive labor to non-productive drill and display, a strange return, under greatly modified conditions, has been made to that earlier state of society in which the army was the whole mass of the male population capable of bearing arms. Universal obligation or liability to personal service as a soldier is recognized by Germany, Austria, Hungary, Greece, Italy, France, Spain, Portugal, Denmark, Switzerland, and Turkey. In Belgium the army is recruited by conscription, in Russia mainly by conscription, and in the Netherlands and in Norway and Sweden partly by conscription and partly by voluntary enlistment. According to the Swiss constitution, there can be no standing army within the federal territory. The following table, quoted by Kolb from a paper by Freiherr von Fircks in the *Journal* of the Prussian statistical bureau, gives an estimate of the military forces of the principal states in 1859 and 1874:—

	1859.		1874.	
	Total Army.	Available for Offence.	Total Army.	Available for Offence.
Germany	836,800	483,700	1,261,160	710,130
Austria-Hungary	634,400	443,800	856,980	452,450
Russia (European).	1,134,200	604,100	1,401,510	665,890
France	640,500	438,000	977,600	525,700
Italy	317,650	156,450	605,200	322,000
Belgium	80,250	53,800	93,590	59,140
Netherlands	58,550	42,200	64,320	32,430
Great Britain	245,800	77,300	478,820	71,860
Denmark	57,550	38,450	48,700	30,500
Sweden and Norway	134,900	46,300	204,510	54,910
Total	4,230,550	2,459,750	6,110,690	3,012,560

Thus the only nation which had decreased its force during that period was Denmark; France, instead of having one soldier to every 58 of the population, had one to every 37; Great Britain, instead of one to 119, had one to 71. Since 1874 matters have not greatly changed. According to the *Almanac de Gotha* for 1878, the several states rank as follows, taken in the order of the strength of their forces in time of peace:—

Russia	787,998	Belgium	45,970
France	494,105	Sweden	36,495
Germany	418,821	Denmark	35,699
Austria-Hungary	296,218	Portugal	34,203
Great Britain	233,872	Montenegro	30,000
Italy	220,690	Roumania	17,169
Turkey	157,667	Norway	12,755
Switzerland	106,102	Greece	12,188
Spain	100,000	Servia	4,222
Netherlands	52,930	Luxembourg	634

The total amounts to upwards of 3,000,000, or very nearly the population of Scotland or of the largest city in the world: in other words it forms one per cent. of the whole population of the Continent, more than one in fifty of the male population, or probably about one in fifteen of the adult male population. The expense incurred is enormous,—the average sum paid by each individual for the defence of his country being, according to the *Almanac de Gotha*,—

	Francs.		Francs.
1. France	24·86	11. Denmark	6·58
2. England	21·45	12. Greece	5·81
3. Germany	10·10	13. Norway	5·67
4. Spain	8·81	14. Switzerland	4·51
5. Italy	8·63	15. Turkey	3·88
6. Belgium	8·23	16. Roumania	3·65
7. Portugal	7·58	17. Servia	3·21
8. Austria-Hungary	7·35	18. Luxembourg	2·46
9. Russia	7·26	19. Montenegro	2·14
10. Sweden	6·93	20. Netherlands	2·06

The maritime nations, almost without exception, maintain a considerable navy for warlike purposes; and the greater powers have lavished their wealth on experiment after experiment in the endless task of mutual competition for the most destructive and indestructible fleet. In 1877–78 Britain had 58 ironclads (of which 47 are described as efficient), France, 58, Germany 20, Russia 29, Austria-Hungary, 14, Italy 16, Turkey 15 large and 18 small, Spain 10, and the Netherlands 17. The difference of size and structure of the individual vessels makes the fleets of the several countries practically incommensurable in a general survey; and without the actual test of conflict it would be hard to say which of the approximately equal equipments is the most powerful. An American official[1] investigator in 1877 decided in favor of Britain, which not only manufactures her own armored ships, but has constructed a large number of vessels for Russia, Turkey, Spain, Holland, Italy, Denmark, Greece, and Portugal.

National debts.

A most important result of the military expenses of the different countries has been the extraordinary development of national debts. In 1848 the total for all the European states was about £1,700,000,000; by 1873 it had increased to £4,680,000,000, or at the rate of £119,000,000 annually. Each successive war, the Crimean, the French-Austrian, the Prussian-Austrian, and the French-German—has added to the load. Mr. Robert Dudley Baxter, in a paper in the *Journal of the Statistical Society*, 1875, arranged the countries in groups according to the rate of interest they paid on the market price. The states of low interest, paying from 3 to 4 per cent., were the United Kingdom, Denmark, Holland, Belgium, and Germany; the states of moderate interest, 5 to 6½ per cent., Russia and France; the states of high interest, 6½ to 10 per cent., Portugal, Hungary and Austria, Italy, and Turkey; while Spain, paying upwards of 16 per cent., ranked as a state of excessive interest. According to a table furnished by Dr. Kolb, if the several national debts were equally distributed over the respective populations, every inhabitant of Portugal would have to pay about £27, every inhabitant of France about £25, 4s., of Great Britain £24, 15s., of Spain £22, 10s., of the Netherlands, £18, 18s., of Italy £16, 16s., of Turkey £13, of Austria-Hungary £10, of Belgium £5, 17s., and of Russia £5, 5s. The country which ranks lowest is Switzerland, which has no standing army,—the average for every man being there only about 8s. or 9s. Were it not for the enormous development of European commerce such a state of matters could not be supported, and even as it is several countries have been practically, if not formally, bankrupt during the present century. The preceding table gives the annual revenues of the different countries.

	Income.	Expenditure.
France (1877)	£106,885,620	£106,691,868
Russia (1877)	81,539,714	81,252,857
Great Britain (1877)	78,565,000	78,125,000
Italy (1877)	59,564,396	56,915,096
Austria (1877)	37,663,781	40,556,947
Prussia (1878)	32,581,920	32,581,920
Spain (1877)	29,433,000	29,430,000
Hungary (1877)	23,341,042	21,447,457
Belgium (1877)	10,161,830	9,857,700
Netherlands (1876)	8,642,556	9,539,139
Portugal (1877)	5,346,661	5,510,200
Sweden (1878)	4,782,778	4,782,778
Roumania (1876)	3,915,776	3,915,776
Denmark (1877–8)	2,734,189	2,239,443
Norway (1877–8)	2,235,000	2,235,000
Switzerland (1876)	1,659,496	1,704,880
Greece (1877)	1,401,678	1,466,760

Commerce.

The commerce of Europe may be said to have had its beginning when the people of the early stone period bartered on from horde to horde the flint or jade best fitted for their weapons, and there is reason to believe that far back in prehistoric times the amber of the Baltic found its way across the Alps to add a new element to Italian decoration. It was not till the Roman period, however, that the great lines of traffic were distinctly laid; Rome was the first European city whose necessities and desires formed as it were a great centre of combustion requiring a continual current from all directions to feed the ever-brightening flame. Since the 10th century, when the northern nations had finally settled in their present seats, the commercial activity of the continent has increased from generation to generation, and in none has it made a greater advance than in the present. Europe has now a hundred Romes; and the mightiest of them is to the Rome that then was as the world of the 19th century is to the "world" of the first. Along with increased necessities and more varied desires have been developed greater possibilities of supply and satisfaction; and the commerce of Europe has become the commerce of the globe.

The great indispensables are food and clothing, and in regard to neither of these is Europe self-sufficing. Austria, Russia, Roumania, and Denmark are the only countries that grow a sufficient quantity of the cereals to maintain a regular export, and even these are indebted to foreign supply for much of their ordinary food materials. Russia annually produces about 644,000,000 bushels of grain, and of this she can spare upwards of 120,000,000. The chief corn-growing districts are New Russia and Bessarabia, and the principal ports of outlet are Odessa, Taganrog, Rostoff, Mariupol, and Berdiansk. England and France purchase most of the wheat, and Germany most of the rye. Austria-Hungary produces about 400,000,000 bushels; but it is only in favorable years that the export exceeds the import. Roumania has an average harvest of about 89,000,000 bushels, and exports to the value of about £4,500,000. Denmark counts about 79,000,000 bushels of produce, and has a surplus of 65,000,000. England and Ireland derived in 1874 about 63 per cent. of their foreign wheat from the United States and Canada, 11 per cent. from Russia, 8 per cent. from Germany, and 4 per cent. from Chili. The value of the whole import amounted to upwards of £51,000,000; and it is calculated that on the average England requires the produce of about 4,500,000 acres of foreign wheatfields. The average harvest in France yields about 658,000,000 bushels; and in favorable years she has a small export. Germany produces about 715,000,000, but requires at least £80,000,000 worth additional. Belgium's medium harvest reaches 64,000,000 bushels, but it is never sufficient for the population; in 1873 they paid upwards of £64,000,000 for foreign supplies. The Netherlands produce about 31,000,000, and purchase to the extent of £3,000,000. The Italian harvest furnishes about 282,000,000 bushels, besides 27,000,000 bushels of rice, but the import exceeds the export sometimes to a very high value. In favorable years Sweden and Norway yield 82,000,000 bushels; the former country exports oats and barley, and imports rye, wheat, and meal; the latter, with a surplus of oats, requires a large foreign supply of all other grains. The Spanish produce varies from 27 to 200 millions of bushels, but about £2,300,000 worth have to be imported. Portugal, with a mean harvest of 30,000,000 bushels, purchases to the amount of £250,000. For the whole of the continent the total harvest may be stated at about 4,893,000,000 bushels.

Europe finds greater difficulty in satisfying its demands for animal food. The average consumption per head of population is rising in all the principal countries; and though the modern stock-raiser can produce a greater quantity of flesh per ox or sheep, it is in several districts found more profitable to turn the ground to other uses, and sheep and cattle farming are consequently on the decline. There has thus grown up a great import trade, not only of living animals, but, within the last twenty years, of preserved meat, the principal sources being North and South America and Australia. The trade is yet in its infancy, and trustworthy statistics are not readily accessible.

---

[1] King, *The War Ships of Europe*.

An ever-growing addition to the food supplies of Europe is made in the form of what are called colonial wares—sugar, tea, coffee, etc. Though the native production of beet sugar amounts on an average to 22 or 23 million cwt. per annum, that would only furnish about 7 ℔ on an average to each inhabitant; while as far back as 1866, according to Robert Burger's calculation, the average demand was more than 11 ℔ per head, and in Britain had reached about 42 ℔. The consumption, moreover, has since then increased enormously—Great Britain having advanced to 62 ℔ per head, France from 13 ℔ to 19 ℔, and Germany from 10 ℔ to 15 ℔. Almost the same might be said of tea, in the consumption of which Britain again stands first, requiring about 4 ℔ a head per annum; and of coffee, of which Belgium requires the greatest average supply, or about 9 ℔ a head. And to all this must be added the multitudinous articles of consumption from far and near that give such a cosmopolitan air even to an ordinary grocer's shop.

For that most universal of all clothing materials, cotton, Europe is almostly entirely indebted to other parts of the world; and though it grows a large quantity of wool and no inconsiderable amount of silk, its demand for both far exceeds its domestic supply. So much, however, of what it imports is again exported in the form of manufactured goods, that it is almost impossible to obtain a correct estimate of its true consumption. For details on these enormous trades the reader may consult the separate articles. The European production of wool was reckoned in 1871 at upwards of 562,370,000 ℔,—England contributing 159,000,000, France 91,108,000, and Russia 90,760,000 to the total. The production of silk is about 12,000,000 ℔.

Some idea of the relative position of the separate countries in the general traffic of the world may be obtained from the following table of the strength of the commercial marine:—[1]

	Vessels of all kinds.	Steamers.	Tons.	Men.
Great Britain	22,200	2,557	5,533,000	210,000
Germany	5,082	219	1,285,000	40,000
France	5,115	316	1,141,000	35,000
Italy	4,808	102	1,080,000	50,000
Norway	6,990	118	1,020,000	48,000
Holland	2,000	52	491,000	16,000
Spain	4,500	150	392,000	20,000
Greece	2,100	7	392,000	20,009
Russia	3,160	192	383,000	20,000
Austria	3,000	95	373,000	32,000
Sweden	3,300	390	353,000	32,000
Denmark	2,800	88	186,000	......
Turkey	1,500	10	176,000	6,000
Portugal	800	16	113,000	8,000
Belgium	70	12	30,000	1,400
Approximate totals.	87,100	5,544	15,863,000	550,000

Industries.

If it were not for the enormous development which has been attained by its manufacturing industries, Europe would have no means of paying for what the other continents can afford to send; it has comparatively few raw materials which it can give in exchange, and so it pays for them with its labor and its skill. The countries which rank as emphatically industrial are Great Britain, France, Saxony, Switzerland, Belgium, Würtemberg, Prussia, and Alsace-Lorraine. In the manufacture of iron Britain stands at the head of the list, especially for steel, wire, rails, and cast-iron. In the first department its principal rivals are Germany, France, Austria-Hungary, Sweden, and Belgium; in the second Germany, France, Sweden, and Belgium are also exporters, and Austria-Hungary and Italy manufacture for their own markets; and in the third the state of matters is much the same, with the exception that several other countries are also producers in a small way. The manufacture of cast-iron is more widely distributed, forming an important industry not only in most of the countries already named, but also in Italy, Spain, the Netherlands, etc. The same position of supremacy belongs to Britain for its cutlery, though a great deal of attention is devoted to this department by all the chief Continental nations. Austria, for example, produces yearly about 600,000 scythes, more than 1,000,000 sickles, and about 200,000 straw knives, and of the first it exports a large number, especially to Russia. Vienna has a great manufactory of fire-proof safes, and ranks with Steyr, Letten, Ferlach, Weipert, and Prague in the production of military weapons. Prussian pens and needles are well known throughout the continent; and still better her cannon and needle-guns. In the manufacture of cotton, brass, and lead, the first place belongs to France and Great Britain; and in that of zinc to Belgium, Great Britain, and Prussia. In bronze France is distinguished both by the quantity and variety of her productions. Great Britain, France, Austria, and Germany are the only countries in which scientific instruments are made in large numbers, and with excellent finish; in the manufacture of musical instruments the same countries stand high, but have a greater number of competitors. In watchmaking Britain, France, and Switzerland carry off the palm; the Belgian clocks are accounted excellent; and the products of the Black Forest in the same department are too well known to need even a passing mention. The ruder branches of the ceramic art are almost universally cultivated, but only a few countries furnish a large export of the finer wares. Porcelain is largely manufactured in Bohemia, at the royal potteries of Meissen and Berlin in Prussia, at Dresden in Saxony, at Limoges in France, at Copenhagen in Denmark, at the imperial potteries of St. Petersburg, and at Stoke-upon-Trent and Worcester in England. Freiburg in Breisgau supplies the markets of a large part of the world with porcelain button knobs and beads; and the Thüringerwald and Sicily are noted for their little porcelain figures and ornaments. The manufacture of glass is also of the widest distribution. Austria-Hungary numbers about 300 glass-works, Germany rather more, Britain upwards of 220, France 175, Italy 70, and so on. Bohemia gives its name to a well-known class of goods; France takes the first place for its beads and glass jewelry; and Belgium is perhaps even better known for supplying the common wants of the glazier. The polishing of precious stones is carried to greatest perfection in France; but Vienna, St. Petersburg, London, Dublin, Berlin, and several other great cities also rank high. Amsterdam has long been the principal seat of the diamond trade. Bohemia and Baden find a valuable industry in the working up of their garnets and rock crystals; and Oberstein in Oldenburg is remarkable as the source of nearly all those fancy articles in agate which under various names—Scotch pebbles and the like—are sold throughout Europe. Rome is the principal seat of the production of cameos and mosaics, and marble-cutting has attained its greatest development in Tuscany. It is impossible to enter into detail on the various industries which use wood as their raw material; almost every country and district has its share, and they differ not so much in the nature as the finish of the articles which they produce. In the produce of the turning-lathe Austria, Germany, England, and France rank highest, and they also keep their position in the department of wood-carving. Italy is first in straw-plaiting, which is of prime importance in Tuscany; and next come Switzerland and Belgium. Leather-making and its associated industries are of universal distribution; the brush manufacture has reached its fullest development in England; and hair is most successfully turned to artistic account in France.

In the great department of spinning and weaving Britain stands *facile princeps*. Of the cotton manufacture, especially, it has long been the greatest centre, not only in Europe, but in the world; but within the present generation the industry has been rapidly developing in Germany, France, Russia, and several other Continental countries. The relative position of each is indicated by the following table of the number of spindles employed in the trade.

England	39,500,000	Spain	1,400,000
France	5,200,000	Belgium	650,000
Germany	5,100,000	Italy	500,000
Switzerland	2,060,000	Scandinavian states	300,000
Russia	2,000,000	Netherlands	230,000
Austria	1,600,000		

In wool-spinning and cloth-weaving the chief countries are again Britain, Germany, France, and Belgium, and to these succeed Austria, Italy Russia, Sweden, and Spain. As minor or domestic industries both branches have a very wide distribution. The greatest amount of silk is spun in Italy and France, and the latter country holds the first place in silk-weaving, though she has powerful competitors in Germany, Britain, and Switzerland. Great Britain again outstrips all her rivals in the general manufactures of flax, hemp, and jute; in linen thread she is excelled by France, and in the extent of her rope works by Russia. Linen weaving is widely distributed as a domestic industry, and is rapidly developing as a factory industry in Germany, Belgium, and the Netherlands. The state of the paper trade may be gathered from the following statistics for 1874:—

---

[1] See Neumann-Spallart's contributions on the Trade of the World to the several volumes of Behm's *Geographisches Jahrbuch*.

	Paper works.	Produce. Cwt.
*Germany	423	3,535,000
*Britain...	274	3,535,000
*France	404	2,907,000
*Austria	130	1,414,000
*Italy	67	943,000
Russia	66	658,000
*Belgium	19	442,000
*Norway and Sweden	20	265,000
*Spain	17	255,000
*Holland	10	141,000
Portugal	19	117,000
Denmark	5	70,000
Switzerland	30	19,000

The countries marked by an asterisk export part of their production. In paper-staining France ranks first, and Britain in the making of papier-maché. Sugar-refining is of most importance in Britain, France, the Netherlands, Belgium, and Germany; and the more modern manufacture of chocolate flourishes best in France and Spain. Britain brews a greater quantity of beer than any other country, and Germany, Austria, and Belgium come next in order; Germany and France are the greatest manufacturers of brandy, and Holland has almost given its name to one of the principal liquors; but this whole department of industry is of the very widest distribution. Among the more peculiar and local branches may be mentioned the Kirschwasser and Eau de Cologne of Germany, the plum brandy of Roumania, Servia, and Bosnia, the aniseed liqueur of Albacete in Spain, and the famous productions of the monastic establishment at Chartreuse. Vinegar is most largely and successfully manufactured in France. In the preparation of tobacco, Germany stands first; and the Netherlands are indebted for a large trade in this department to their East Indian colonies. The soap manufacture has reached its highest development in France and Britain; while the greatest exporters of tallow are Russia, Roumania, and Servia. Sweden is especially famous for its matches, which are sent to all parts of the world. The preparation of ultramarine is of great importance in Germany; and Austria has unrivalled manufactures of white lead in Carinthia.

Such are a few of the main features of that wonderful industrial activity which is daily acquiring a more varied aspect and extending over a wider area. The younger nations are developing their resources, and turning their attention to industries that they had long neglected; and in the older nations almost every year sees an addition to the bewildering multiplicity of human occupations.

Railways.

While most of the several countries, as appears by the accompanying table, are on the whole fairly supplied with internal railway communication, and a few have developed a nearly perfect system of primary and secondary lines, much has still to be done before the general international system will be approximately complete. Of natural obstacles the mountains are the most formidable, and at the head of the mountains in this respect, as in others, stand the Alps. Between all the countries of northern and central Europe regular traffic is easily maintained: the north of France, Belgium, Holland, and the north of Germany are practically one as far as the great network of railways is concerned. Between France and southern Germany the connection is not so close, though the Franco-German frontier is crossed by four or five lines, and the Swiss system, which is well developed, affords several additional routes. Between Germany and Austria there are almost equal facilities, more especially along the borders of Bohemia and Saxony. Eastwards and southwards in Poland, Russia, and Austria, the meshes of the net grow very wide, but the main threads are knotted together and satisfy the necessities of international communication. Such is the state of the case in the countries of central Europe; but if the traveller wishes to proceed by rail to any of the three southern peninsulas, he finds himself in a very different position. From France he can enter Spain only by two routes, one of which takes him round the western end of the Pyrenees, and the other, opened in 1878, round the eastern end; at all other parts of the frontier the mountains bid defiance to the engineer. From Spain, where he will find the internal system still very incomplete, the traveller may cross the Portuguese frontier and proceed by rail direct to Lisbon, but if he wish to reach Oporto without visiting Lisbon he must resign himself to the old-fashioned road. His case is better if he turn in the direction of Italy: from France he may glide into Italy through the tunnel of the Col de Frejus, or as it is popularly called Mont Cenis, which was completed in 1870 and opened in 1871; or from Bavaria he may traverse the other extremity of the Alps by the Brennerbahn, and reach the Lombard plain by the valley of the Adige. By all other routes he must in the mean time accept the service of the diligence; but workmen have been busy since 1871 under the massif of St. Gotthard, and within a few years he may be able to pass right through from Zurich to Bellinzona and Milan. It has also been proposed to effect a communication between the railways of north Italy and the line of the Rhone valley by means of a tunnel through the Simplon; and one German engineer at least, Sturm, has a scheme for boring under Mont Blanc itself. Once in Italy, the traveller can proceed as far as Otranto at the eastern end of the peninsula, or to Reggio at the western. If, instead of Italy, it be his desire to visit the countries to the south of the Danube, the railway altogether fails him. By Austrian lines he may reach Sessek on the Save, Essek on the Drave, or Bazias on the Danube; or if he go round by Galicia, he may proceed south through Bulgaria, cross the Danube at Rustchuk, and continue as far as Varna on the Black Sea. But at no point is there any connection with the Turkish system, or rather fragmentary beginnings of a system: the lines from Constantinople and Aghatch which meet to the south of Adrianople, stop short in the valley of the Maritza, and the line from Saloniki proceeds only as far north as Uskub. In Greece there is but one little line, from the Piræus to Athens. By the Russian railways the traveller can journey direct south to Odessa, Nicolaieff, or Sebastopol on the Black Sea, to Taganrog or Rostoff on the Sea of Azoff, or even to Vladikavkas in the Caucasus. Eastward he may advance as far as Tsaritsin or Saratoff on the Volga, and to Orenburg at the end of the Ural range. North-eastwards his limits are Nizhni-Novgorod and Vologda. According to the plans of the Russian Government, a few years will see the construction of lines of communication with eastern Siberia on the one hand and the new provinces of central Asia on the other. It is sufficient to mention the projected tunnel between France and England. The following table gives the length of the railway lines in the several countries for 1860 and 1875:—

	1860.		1875.	
	Kilometres.	Miles.	Kilometres.	Miles.
Great Britain	16,791	10,433	26,870	16,696
Belgium	1,729	1,074	3,517	2,185
Germany	11,253	6,997	27,980	17,386
France	9,316	5,790	21,587	13,413
Austria	5,402	3,436	17,368	10,792
Russia	1,384	869	18,488	11,488
Italy	1,705	1,055	7,704	4,787
Spain	1,916	1,190	5,796	3,601

Netherlands	259	160	1,895	1,177
Switzerland	936	598	2,066	1,283
Turkey	....	....	1,537	955
Roumania	....	....	1,233	766
Denmark	109	677	1,260	782
Portugal	131	814	1,033	641
Norway	68	42·2	555	344
Greece	....	....	12	7½

Since 1875 the railway contractors have not been idle. At the end of 1876 there were 16,872 miles open for traffic in Great Britain, and upwards of 5000 miles in course of construction. In the beginning of 1877 the Belgian lines amounted to 2228 miles or 3580 kilometres, and the French lines to 14,078 miles or 22,671 kilometres.

Telegraphs. The telegraphic system, as appears by the accompanying table, is well developed throughout the continent, more especially in Switzerland, Great Britain, Belgium, Bavaria, and Würtemberg. As far as it is international, it is largely indebted to British enterprise and capital, and many of the most important companies have their centres in London. All the maritime countries have submarine cables. Norway has no fewer than 193, with a total length of 1233 nautical miles; Denmark 29, with a length of 101 miles; and Holland 18, with a length of 36. The three Russian cables of the Baltic have a total length of 62 miles, and unite Cronstadt with the capital, and the islands Ösel and Aland with the continent. Of the 12 Italian cables the most important, about 118 miles long, communicates with Sardinia; and of the 6 Spanish three are devoted to Iviça, Minorca, and Majorca. Most of the 26 French cables are short, with the exception of that which stretches across the Mediterranean from Marseilles to Algiers. Great Britain has a large number communicating with various parts of the continent, as well as with Ireland, the Channel Islands, Orkney and Shetland, the Hebrides, etc. Of prime importance to the continent at large are the great transatlantic cables, four of which have their European termini in the west of Ireland, while a fifth, the longest yet laid down, stretches from Brest in Brittany 2585 miles to St. Pierre near Newfoundland, and a sixth from Lisbon to Pernambuco in Brazil. Two others are projected —one from Portugal, and another from the Shetland Islands round by the Faroes, Iceland, Greenland, etc. Direct communication is maintained between England and India by the lines of the Eastern Telegraph Company, and other lines continue the system as far as Australia on the one hand and Japan on the other.

Telegraphic Communication in Europe in 1875.

Canals. Within recent years fresh attention has been directed to the older canal-system, which was by many regarded as having had its day. Not only are the canals which had fallen into partial decay being in many cases restored, but new canals are either constructed or planned. Without entering into the details of the separate national systems, some idea may be formed of the extent of this means of communication by the following facts. We may pass from the Rhone to the Loire, and from either river to the Seine; the Seine in its turn is connected with the Meuse and the Rhine; the Rhine communicates with the Danube in the south, and with the Ems and the Weser in the north; the Weser is already in communication with the lower part of the Elbe, and it is proposed to construct a line of canals to unite these rivers further inland; from the Elbe we pass by the Spree system to the Oder; the Oder, by means of its tributary the Wartha, gives access to the Vistula; and the Bug, a tributary of the Vistula, brings us to the great Russian network of rivers and canals by which we can journey from the Baltic to the Black Sea or the Caspian, or from either of these to the White Sea in the north. Thus it appears in brief that water highways exist between all the great river-systems and all the principal seas. It was only in the summer of 1876 that the Dutch opened a new canal between Amsterdam and the sea; in 1877 the senate of Finland voted 200,000 rubles for a canal between the Baltic and the White Sea; and very extensive additions are proposed to the German system. A scheme has even been started by an American engineer, H. C. Spalding, for connecting the Black Sea and the Caspian, and thus increasing the area of the latter at the expense of the neighboring steppes; and a less quixotic proposal contemplates a canal from the Don to the Volga across the ridge of nearest approximation. In France there is already a line of water-way between the Bay of Biscay and the Mediterranean, but it is only available for inland traffic; and the proposal is now entertained of constructing nothing less than a ship-canal. An earlier and more extravagant project to make such a canal through Spain from Bilbao to the valley of the Ebro has naturally remained a dead letter.

Education. Since the 18th century, there has been great advance in the general educational condition of Europe. That it is the duty of every state, if not to provide instruction for the rising generation of citizens, at least to see that it is provided, is a principle more and more thoroughly recognized and acted upon; and the obscurantist doctrine that the lower classes become more revolutionary and dangerous by becoming more intelligent and better informed is less frequently employed as an open argument. Even in Turkey a law was at least passed in 1869 requiring the establishment of secondary schools and gymnasiums in the principal towns; and education is one of the matters dealt with in the proposed reforms of 1878. How slow the movement has been even in the more civilized countries is strikingly shown by the fact that England has not yet realized the far-sighted schemes suggested more than a thousand years ago by her wise West Saxon king, Alfred. The educational reformers of almost every country have had a hard battle to fight in their endeavors after a satisfactory organization, and compromise and half-measures have frequently been the order of the day. From time immemorial the clergy have had, and they certainly for a long time had a right to have, a predominant share in the control of all educational matters throughout Europe; the sacred books of the various forms of religion or doctrinal compendiums of individual sects have been the most familiar manuals of primary instruction; and even when the teacher has been a layman, ecclesiastical supervision more or less efficient has been added. The present tendency, even in countries like Italy on the one hand, and Sweden on the other, where there is little difference of creed among the population, is decidedly in favor of the teachers being laymen and the instruction secular. That the clergy do not readily acquiesce in the changes that diminish their influence is excusable; but at the same time their demands have occasioned the most lamentable obstruction to educational progress.

In order that primary education may be rendered universal, it has been found necessary to make it compulsory; and this has been done either directly or indirectly in all the great countries of Europe. It is now easier to name those that have not adopted direct compulsory measures than those that have adopted them. The former list includes France, Russia (with the exception of the Baltic provinces), Finland, Belgium, Turkey, Servia, and Montenegro. In England, the gradual extension of the school-board system practically involves the extension of compulsory education, though the question is left in the hands of local authorities instead of being decided once for all by the central legislation. Owing to the differences existent between the organizations of the several countries, it is impossible to institute an exact comparison: but the following table, revised from Brachelli's, presents an approximate survey:—[1]

	Year.	Schools of popular instruction.	Scholars.	Scholars to every 1000 inhabitants.
Switzerland........	1872	5,088	413,789	155
German empire...	1872	56,000	6,000,000	152
Luxembourg	1874	644	28,437	142
Norway	1873	6,502	243,969	138
Sweden	1875	8,123	606,876	138
Netherlands	1873	3,790	500,059	136
Denmark............	1867	3,064	226,679	135
France	1872	70,179	4,720,000	131
Belgium	1872	5,678	618,937	123
Austria..............	1875	15,166	2,134,683	100
Hungary	1872	16,300	1,464,775	94
Great Britain.......	1876	17,787	2,340,277	83
Spain	1873	27,760	1,381,972	82
Italy	1873	42,920	1,827,381	70
Greece................	1874	1,227	81,449	50
Finland	1873	1,382	76,477	42
Portugal	1870	3,500	140,000	32
Roumania	1873	2,221	82,145	17
Servia	1874	517	23,278	17
Russia................	1873	23,183	1,009,037	14

The countries of southern and eastern Europe are all very low in the scale; but several of them, and notably Italy, Greece, and Russia, are making rapid advances. The last of these has great difficulties to contend against in the extent of its territory and the sparseness of its population; but such a fact as the following speaks for itself: "In 1866," says M. Hippeau,[2] "in every 100 conscripts only one could read and write; in 1870 this number had risen to 11 in the 100." Several of the local boards have recommended the adoption of obligatory attendance at school. Much less hopeful is the condition of Spain, where at the last census (1860) 72 per cent. of the population could neither read nor write. Yet even there the movement is in the right direction. A fine contrast is afforded by the Scandinavian countries, where the peasantry have long been accustomed to relieve the tedium of their winter nights by reading the sagas of their native land, and by some of the Swiss cantons, where there are only 4 per cent. of the population totally uneducated. In France, according to the official statistics of 1875, there are 30 persons in every 100 unable to read or write; and in Belgium, according to the results of the census of 1866, 42 in every 100 above seven years of age are in the same condition. The high position of the German empire is mainly due to Prussia, which may be regarded as the forerunner of educational progress in Europe. Among the other states the differences are very considerable. Brunswick, Anhalt, Oldenburg, Saxony, and Thuringia rise above the average of 152 scholars to the 1000 inhabitants; Mecklenburg and Bavaria sink as low as 121 and 126 respectively. A high position is held by the free city of Bremen, where the public expenditure for education has risen from 0·60 of a mark in 1847–51 to 8·45 marks in 1872–76 for each head of the population. In Austria the contrasts between the provinces are enormous,—every thousand inhabitants in Silesia, Bohemia, Moravia, or Tyrol sending from 130 to 136 children to school; while in Galicia, Dalmatia, and Bukovina the numbers are only 29, 23, and 19.

If statistics are unsatisfactory in regard to the condition of primary schools, they are still more unsatisfactory as regards the institutions for the training and education of the primary teacher. Till some approximation be made between the systems of the several countries, it conveys almost no information to say that in Prussia there are 107 and in Russia 45, in Switzerland 32 and in Portugal 6. And still more impossible is it to institute a comparison with respect to the secondary schools and the various institutions devoted to instruction in special departments of art or science. In all the more advanced countries they are increasing in number and in the specialization of their work.[3]

In Germany there are twenty-one universities, including the academy of Münster, with about 1983 professors and teachers, and a total attendance of 19,000 students. The best known are Berlin, Leipsic, Göttingen, Halle, Tübingen, Bonn, Heidelberg, Jena, and Erlangen. In Austria-Hungary there are ten, with 1018 professors, and upwards of 12,000 students. Italy numbers one more than Germany, with 1093 professors, and not far from 10,000 students. Russia has nine, including the Finland university of Helsingfors, and the practically German university of Dorpat. The total teaching staff numbers upwards of 600, and the students more than 7000. The four Scandinavian universities of Upsala, Lund, Christiania, and Copenhagen, count 280 professors and 2700 students. There are four in Holland, inclusive of the Amsterdam Academy, and four in Belgium, the number of professors being respectively 149 and 229, and that of students 2056 and 2272. Since the addition of Geneva, Switzerland has the like number, with a teaching staff of 250 to 300, and an attendance of upwards of 1200. Spain boasts of ten universities with 400 professors, and, if her statistics are correct, has more than 15,000 students. Portugal, in its one famous institute at Coimbra, has about 1000 students, many of whom are from Brazil and the colonies. A university was founded at Athens in 1837, another at Belgrade in 1838, and a third and fourth at Bucharest and Jassy in 1864. The professors number in all 128, and the students upwards of 2000. In France the organization of the higher education is peculiar: Bordeaux and Lyons are the only two cities besides Paris which have all the five faculties of theology, law, medicine, science, and literature, and it is only in Paris that they are incorporated into a "university." In sixteen other towns there exists one or more of the separate faculties. The professors in France exceed 420, with 14,500 students. The Catholics have free "universities" at Angers, Lyons, and Paris. Making allowance for defective statistics, it may be said that continental Europe has about 7000 persons engaged in university teaching, and that the students number from 88,000 to 90,000. In Britain the universities differ greatly from each other in constitution and arrangement. Oxford and Cambridge have together about 80 professors and over 5000 undergraduates. London university, which is merely an examining board, had 17,312 candidates for matriculation in 1877. Durham numbers 5 professors and 109 students. In the four Scotch universities there are 102 professors and about 5000 students. The Queen's university, Ireland, has 54 professors and 745 students, and the Dublin university 39 professors and 1200 students.

Europe, and especially northern and Germanic Europe, has long been distinguished from eastern and southern countries by the greater social and educational equality existing between the sexes; but in this, as in so much else, there is still abundant room for improvement. A powerful movement has set in towards a fuller recognition of the rights of woman; and the right to instruction is recognized as one of the most fundamental. A greater assimilation is in most of the more civilized countries being effected between the educations given to boys and girls; and a powerful party, with powerful arguments, support the thesis that equal opportunities should also be afforded to young men and to young women. In Prussia the general movement is represented by the Victoria or Lette Union at Berlin, and the Otto Petter Union at Leipsic, both of which have founded institutions for the higher education of women. The Jews of Frankfort-on-the-Maine have established two important schools—the *Philanthropinum* and the *Müsterschule;* and the city of Carlsruhe has had a superior school for girls since 1826. The university of Zurich has set the example of the free admittance of women; the London University opened its gates to them in 1877; and the older universities of England and Scotland have at least sanctioned extramural lectureships and condescended to examine if not to teach them. A women's college has been opened at St. Petersburg by Catherine Dikhova under imperial patronage; Hungary has a similar institution; and so the innovation is becoming familiar, and within a generation or two the condition of female education at the beginning of this century bids fair to appear a semi-barbarian state of things hardly credible at so recent a date.

---

[1] The numbers for Great Britain represent those schools only which are under Government inspection, and do not include the statistics for Ireland.

[2] M Hippeau's volumes, *L'instruction publique en Italie*, 1875, *L'instruction publique en Russie*, 1878, etc., afford a convenient popular account of the education of most of the principal countries.

[3] See an interesting *Report on Weaving and other Technical Schools of the Continent, presented to the Clothweavers Company of London*, 1877.

To recapitulate, European education is being more widely diffused, is passing from the control of the clergy or the private citizen into the hands of the state, is becoming more secular and less sectarian, and in its higher departments shows a growing catholicity towards the more modern aspects of thought and life.

Religion. Europe is pre-eminently the country of monotheism, which forms the central doctrine, not only of its dominant religion, Christianity, but also of the minor rivals Judaism and Mahometanism. To none of these three religions has it given birth; and, what is more remarkable, its peculiarly Aryan population have adopted their religion from a Semitic people. The various nations of Europe were still polytheistic when they first entered within the historic horizon; and this polytheism has left more numerous traces of its influence than superficial observers might imagine. Not only have the gods of the Greek and Roman pantheons and their ruder rivals of the north obtained an immortality in the literature and art of all the cultured nations of Europe, but amid the manifold traditions and half-unconscious beliefs of the common people there are fragments of older and baser creeds. Much has still to be done before the amount of such survivals can be estimated with anything like accuracy, but that their number is considerable has been already well established.[1] Nor need it be matter of surprise when we consider how recent the introduction of Christianity into Europe really is, and how, to vast masses of men, it came, not as a conviction of the intellect or a captivation of the heart, but as the infliction of a conqueror or the command of a king; and how, even when it was adopted through the persuasive eloquence of genuine missionaries, it obtained, in many cases, but a divided allegiance, and had to accept and sanctify as best it might the rites and symbolism of the religion which it expelled. That the English still speak of Wednesday and Thursday, that the French have their Vendredi and Mardi, the Italians their Venerdi and Martedi, is of purely historic interest, and implies no lingering attachment to Woden or Thor, to Venus or Mars; but there is no country in Christian Europe in which the popular ideas about supernatural agency in general are not the mongrel products of paganism and Christianity.

Christianity in Europe is broken up into three main divisions,—the Roman Catholic Church, the Greek or Eastern Church, and the Protestant or Evangelical Church; and each of these has received more or less numerous modifications and subdivisions under the influence of different political and social environments. Roman Catholicism not only can boast of the greatest number of adherents, but has the greatest claim to unity, at least in its external organization, and stands in direct contrast to many portions of the Protestant Church, which, while maintaining the superiority of their respective creeds, acknowledge the local and temporary character of their constitutions. The unity, however, has all along been more nominal than real,—rather the beau-ideal of the administrative hierarchy than the actual condition of the organization which they control. Discordant elements have frequently threatened a disruption; severe contests have taken place between the spirit of centralization in Rome and the desire for local independence in individual countries; and in the present century the irreconcilability of two great parties has given rise to the so-called Old Catholics in Germany and Switzerland, who in the latter country at least seem likely to break up into two distinct sections. There are two religious communities in Europe which occupy a special relation to the Roman Catholic Church, the United Greeks and the United Armenians, otherwise known as Catholics of the Greek rite and Catholics of the Armenian rite. They both acknowledge the supremacy of the pope, but they are permitted to retain many peculiarities of organization and ritual. The United Greeks have an archbishop at Gran in Hungary, and another at Lemberg in Galicia. The United Armenians are found in Russia and Austria, but are still more numerous in the Ottoman empire. A schism not unlike that of the Old Catholics broke out amongst them in 1869. The pope by the bull *Reversuris* claimed to exercise certain rights which his predecessors had never enforced, and the Armenians not only rebelled, but drove their patriarch Hussan into exile because he supported the papal authority. The small church of Utrecht, which dates from the year 1704, retains the doctrines of the church of Rome, but emphasizes the superiority of the councils over the pope, and has no connection with the papal organization.

The Greek Church has been divided by political influences into several independent communities, each with its own organization, but all united by a common creed, and the consciousness of a common historic origin. The head of the whole church was at one time the patriarch of Constantinople; but he never had the same supremacy as the pope, and has gradually sunk to be little more than the head of that branch which is subject to the Porte. The Greek Church of Russia began to establish its independence in the middle of the 13th century; till about the middle of the 15th it sent its nominees for the office of metropolitan of Kieff to the patriarch of Constantinople for consecration; afterwards the consecration was performed by a council of Russian bishops; and in 1589 the metropolitan was raised to be the ecclesiastical peer of the patriarch. Peter the Great allowed the office to lapse, and supplied its place by a council or synod, which still remains the central authority in the Russian church, the emperor being recognized as the supreme defender of the faith, and practically holding the place of chief administrator. The Austrian branch of the Greek Church is also governed by a general synod composed of all the bishops under the presidency of the patriarch of Carlowitz, and three provincial synods, the Austrian proper meeting at Czernowitz, the Servian at Carlowitz, and the Roumanian at Hermannstadt. After the declaration of the political independence of Greece, it was natural that there should arise a desire for the independence of the national church; and the patriarch of Constantinople was obliged to recognize its autonomy in 1850. A similar movement took place in Bulgaria in 1870. Though the Greek church is dominant in Russia, there is a very considerable number of sectarian communities. Chief of these are the "Raskolniks" (separatists or non-conformists), who seek to maintain a more scrupulous accuracy in the ritual than the state church enforces. Of totally different character are the heretical sects, some of whom, as the Molokani, show great reverence for the letter of Scripture, while others, as the Skoptsi or Eunuchs, profess the wildest anti-scriptural doctrines, and are carried into excesses of practical fanaticism.

The Protestant churches of Western Europe, which have so marvellously exemplified what naturalists call propagation by fission, may be doctrinally divided into two great groups,—the "Lutheran," which maintain the platform of the great Reformer; and the "Reformed," which have advanced further in their divergence from Roman Catholicism. Politically there are three great classes—state churches, free churches enjoying state endowments, and free churches which either from necessity or choice are entirely independent. To the Lutheran group belong the state churches of Sweden, Norway, and Denmark, and that form prevails also in Prussia, Hanover, and the Baltic provinces of Russia; the "Reformed" includes the Calvinistic churches of Holland and Scotland, and a great number of ecclesiastical organizations in England, Scotland, Switzerland, Germany, and France. The established church of England, though frequently classed with the Lutheran group, has so many points of contact in doctrine and ritual, both with Calvinism on the one hand and Roman Catholicism on the other, that it may be allowed to stand by itself. In Prussia, Baden, and a few of the smaller German states, the two parties are associated under the title of the United Lutheran Church, and have very close relations with the political administration. It is impossible to do more than mention the minor subdivisions of Moravians, Episcopalians, Presbyterians, Methodists, Independents, Quakers, Unitarians, for which the reader may consult the separate articles, and such works as Stäudlin's *Kirchliche Geographie*, Wagger's *K. Statistik*, Döllinger's *The Church and the Churches*, and De Mestral's *Tableau de l'Église Chrétienne.*

Mahometanism or Islam has comparatively few adherents in Europe, and has moreover ceased to be aggressive. If it still occupies in Constantinople one of the noblest of Christian churches, it is more than six hundred years since it surrendered in Cordova one of the noblest of its mosques. Its adherents are mainly Turks, Tatars, and Slavonians; and outside of Turkey they are nowhere very numerous except in southern Russia. Judaism, which at one time had no small proselytizing energy, has for a long period in Europe been nothing but the religion of the people of Jewish descent. It is divided into two great organizations, the so-called orthodox party representing traditionalism, and the reformed party representing freedom of thought. Even among the orthodox considerable laxity of observance is creeping in, and marriages with Christians are growing more and more frequent. Buddhism is still professed by the Calmucks of southern Russia; and the Tcheremisses, and several cognate tribes, and part of the Lapps, Finns, and Samoyedes, still preserve their pagan creeds and customs. The following table from Brachelli gives approximately the numerical strength of the various religions:—

---

[1] See Tylor, *Primitive Culture*, vol. ii.

Countries.	Catholics.	Greeks.	Other Christians, chiefly Protestants.	Jews.	Mahometans.

Changes of territorial distribution.

The political history of Europe begins with the Greeks; but while they contributed more extensively than any people have done since to the theory of government, they have left practically no trace of their political organization in the present association of states. From first to last, in spite of religious and political confederations, and of the unifying influence of the Macedonian hegemony, they retained what in modern phraseology would be called their particularism,—each city or state working out its own political development and testing the value of the various forms of political life for itself. The Greeks were not a conquering people; they felt nothing of the land-hunger of modern nations; and even the great conquests to which they were led by the Asiatic genius of Alexander the Great did not present themselves as acquisitions of territory. They were great founders of cities, and their colonies were distributed along the coasts of Europe from Spain in the west to the Black Sea in the east; but if all the ground that they thus occupied were added together, it would form a comparatively small country. The city, wherever it was, continued an integral part of Hellas, but Hellas was rather the name of a people and a civilization than of a country or a state. In this respect no greater contrast could be found than that afforded by the next people of European history. The history of Rome is almost from its beginning to its close a history of conquest; the limits of its territorial advance were no sooner fixed than the period of decadence set in. Where the Greeks had planted a city the Romans subjugated a region. And thus it is that to the present day the lines of Roman organization are as distinctly traceable on the political map as the lines of Roman roadway in local topographies.

As the Greeks had been the great defenders of Europe from the encroachments of Persian ambition, so the Romans repulsed the Semitic power of the Carthaginians; and as the defence against the Persians was the great determinating factor in later Greek development, so the repulse of the Carthaginians was the prime factor in the later Roman development. The Punic wars led to the conquest of Sicily and Spain; and the conquest of these gave at least a new emphasis to what was already perhaps a national tendency. In 227 B.C. proconsuls were appointed for the province of Sicily and the province of Sardinia and Corsica; the second Punic war left Rome master in 201 of the greater part of Spain and supreme in the western Mediterranean; the capture of Numantia in 133 put the rest of Spain in its power; the battle of Pydna secured the subjugation of Greece; the campaigns of Julius Cæsar added the vast territory of Gaul to its domain; and when Augustus effected the great change in the constitution which left its effete nomenclature to the 19th century, he was able to adopt the Danube, the Rhine, and the ocean as the north-eastern boundary of the European part of his empire. His rule was paramount in all the region which now comprises Portugal, Spain, France, Belgium, western Holland, Rhenish Prussia, parts of Baden and Würtemberg, most of Bavaria, Switzerland, Italy, Tyrol, Austria Proper, Western Hungary, Croatia, Slavonia, Servia, Turkey in Europe, and Greece. The populations of many of these countries had already begun to be Romanized in language and customs, but most of them were still distinctly aliens. During the succeeding centuries of the empire a few comparatively unimportant oscillations of frontier took place, and a few additional elements were added to the motley conglomerate of Roman citizenship; but the main features were still the same when Constantine introduced his new administrative distribution, and fixed the seat of government in the city which still bears his name. Christianity, which now received the sanction of the civil power, had gradually changed from an organ of political disintegration into an organ of political union. The worship of Christ and the service of the empire formed two powerful bonds of association between the members of discordant races, and even proved strong enough to break up several tribes into two sections,—one of which was Christian and imperial, and the other pagan and barbarian. But even in the reign of Constantine the frontiers were with difficulty maintained: he had himself to resume the contest more than once with several powerful Germanic peoples. Before long, the whole of the outer world to the north-east was in motion. The Visigoths, or West Goths, were pressing on the lower Danube; behind them, in the countries of the Bug and Dnieper, lay the East Goths; and further east were the warlike, horse-loving Alans in the country of the Don and the Volga. Other German tribes or confederations—Franks, Saxons, Alemanni, Longobards—had settled or were settling along the upper Danube and the Rhine, and had crossed or were crossing into Roman territory. Far to the east, over the country now known as Russia, the Scythians and Sarmatians were nomadizing; and in the outskirts, along the Ural, we can dimly distinguish the Magyars, the Avars, the Petchenegs, and other tribes that were afterwards to force their way westward. In the reign of Valens a new impetus was given to the barbarian hordes. The Huns, a wild nomadic people, suddenly appeared on the lower Don, subjugated the Alans and the East Goths, and drove the defeated West Goths across the Roman frontiers. As a Christian people the fugitives obtained permission to settle on the south of the Danube; but the treatment they received from the Roman officials drove them to rebellion; they defeated Valens in the great battle of Adrianople, and threatened to invade Italy itself; and it was not till the reign of Theodosius that they were persuaded by important concessions to take peaceful possession of lands in Mœsia, Dacia, and Thracia.

Plate X.

Hitherto the empire had, in spite of all the confusion of rival emperors and intrusive tribes, maintained a theoretical unity; in 395 A.D. a division was effected which practically proved definitive. Arcadius, the eldest son of Theodosius, became emperor of the East, with his capital at Constantinople; and Honorius his brother became emperor of the West, with his capital not at Rome but at Ravenna. Had the Roman territory been confined to Europe the division would have been extremely unequal, as Arcadius only received the country to the south of the Danube and east of the Drinus, or, in other words, little more than European Turkey and Greece; like the sultan's, his possessions were mainly in Asia and Africa.

Instead of tracing the gradual disintegration of the Western empire, with its monotonous detail of invasions, concessions, repulses, etc., it will be well to pass down to the 6th century, and see what has been effected in the interval. We now find the German race almost everywhere in the ascendant. England is in the hands of the English; the kingdom of the Franks extends from Brittany to Thuringia; the West Goths are dominant in the greater part of Spain

and nearly all the country to the south of the Loire; the Suevi are in possession of the remainder of Spain; the Burgundians occupy a compact territory, which includes, besides the basin of the Rhone and Saone, parts of the contiguous basins of the Rhine, the Seine, and the Loire; and the East Goths, under the sanction of the emperor of the East, hold sway in the rest of western Europe, from Provence to the Danube and from the Alps to the Sicilian Strait. Outside of the old frontier the Gepidæ (also German) have established a kingdom in the country to the north of the Danube; on the north-west they are conterminous with the Lombards; the Thuringians are established to the west of the Böhmerwald; the Saxons lie between the Meuse and the Oder; the Danes are in possession of Denmark, and the other Scandinavian peoples hold the country from which they derive their name. It would seem as if Europe were in a fair way to become a German confederation, or, it might be, a German empire. But all over the old Latin area the Germans are ceasing to be Germans; and beyond that area, both in Europe and Asia, there are other peoples destined to play a part in the settlement of the West. The Bulgarians, a Mongolian tribe, have reached the country between the Dnieper and the mouth of the Danube; the Czechs or Bohemians, already occupy the country which now bears their name; the Croats are to the north of the Lombards; and other Slavonic tribes have pushed south to the coast of the Adriatic.

Plate XI. If we again pass down for about two centuries, the whole scene is changed. The West Goths and East Goths have almost disappeared,—the former only living on in the little kingdom of Asturia in the north of Spain; to the south of the Ebro and the Douro the country is in the hands of Arabs, or Moors, who first crossed the Strait of Gibraltar in 711; the king of the Franks is that Charles the Great, or Charlemagne, who is the mightiest monarch Europe has seen since Constantine, and he has not only extended his kingdom on all sides, but he has been chosen emperor of the West, and his authority is acknowledged from the Ebro to the Elbe, and from the North Sea to the Tiber. A new political power has arisen in the pope, or bishop of Rome, whose spiritual supremacy is beginning to be widely recognized. The Eastern or Byzantine empire is more and more exposed to the intrusion of Slavonians: they have under the name of Servians established a considerable kingdom between the Adriatic and the middle Danube, and, mingled with other races like the Bulgarians and the Avars, they occupy a large region to the north of the Danube. In the country to the north of the Black Sea, as far east as the Volga, has grown up a great kingdom called the kingdom of the Khazars, with its capital at Balangiar or Astrakhan; the people is mainly of Ugrian stock, but it has accepted the Jewish religion, and, allowing complete religious toleration, is mingled with representatives of many nationalities; politically it continues important for centuries as a bulwark against the advance of the Slavonic tribes from the north. Of all these states from the Atlantic to the Volga the one that showed most powerfully at the time, and which has lived most prominently in historic record, is undoubtedly the empire of Charles the Great; but of all it was the first to perish: even the nucleus of his kingdom was divided into two—that of the West Franks and that of the East Franks.

By the end of the 10th century the map again presents great modifications. The Mahometans are still in possession of a great part of Spain, and the northern region has been broken up into several independent states—the kingdom of Leon, the little kingdom of Pampeluna, and the countship of Castile or Burgos. The western Franks now form the kingdom of France with its capital at Paris, and since 987 have been ruled by the dynasty of Capet, which will continue to modern times. The duchies of Gascony, Aquitaine, Burgundy, and Normandy, and the countships of Flanders, Champagne, and Toulouse, have been gathering strength, and will maintain for centuries a certain amount of independence. Germany has recently become the representative of the Roman empire through the coronation of Otto the Great of Saxony; and Otto III. is forming plans for the increase of the imperial power. His authority is recognized by the dukes, not only of Lorraine, Alemannia, Bohemia, and Carinthia, but by those of Spoleto, Benevento, and Salerno, as well as by the minor potentates of Italy, with a few exceptions in the far south. The duchy of Poland and the kingdom of Hungary are less formally and steadily subordinate. Between Germany and France lies the kingdom of Burgundy or Arles, which must not be confounded with the duchy of Burgundy, and whose limits extend from Basel to Provence, including all the lower basin of the Rhone. In the Balkan peninsula the Servian principality maintains its independence, and the Bulgarians have extended their power from the Danube southwards to Thermopylæ. Among the peoples to the east the Russians are already the most powerful; and the great empire of the Khazars has disappeared.

Plate XII. During the next five centuries Europe was full of hurry to and fro, of petty strivings and plunderings, of great wars and invasions, of crusades and conquests. At one time it appeared as if the Scandinavian peoples were to take possession of England, and at another as if the English were to become masters of France; the French attempted the annexation of Italy; the most powerful of the Italian commonwealths extended its authority over the islands and mainland of Greece; all Europe sent forth its armies for the recovery of the sacred sepulchre; and all Europe was in alarm at the advance of the Ottoman power. Amidst all the confusion and conflict, the modern nations were slowly taking shape under the influence of a rapidly developing feudalism, and by the time we reach the 16th century we can speak of France and Germany, of Spain and Portugal, of Poland, Russia, and Turkey, with something of the same meaning in the words as they possessed till the Great Revolution.

In the second decade of the 16th century the house of Hapsburg, in the person of Charles V., attained an unprecedented preponderance. Through the action of the laws of inheritance he acquired the Netherlands, the Spanish monarchy with the kingdom of Naples, and the Austrian states of his paternal grandfather; and in 1519 he was elected to the imperial throne. On his abdication he left the German states to his brother Ferdinand, and the rest of his possessions to his son Philip. Between the various countries thus absurdly united with the Spanish crown there was no kind of cohesion, and even in a period of repose the association could hardly have been expected to last. The 16th century was anything but a period of repose. The extent of the new monarchy raised the rivalry of England and France; the Turkish power was dangerously aggressive in the East; and religious discord added a new and potent element of disintegration. War followed war in rapid succession; and many of the most flourishing parts of the continent were laid waste with a desolation which centuries of peace but partially effaced.

It was not till 1648 that the treaty of Westphalia gave the greater part of the continent another period of repose. The contest of which it was the immediate termination left Sweden the most powerful of the Scandinavian states, with important acquisitions from Denmark and Norway, from Germany, Russia, and Poland. The Protestant Netherlands and Switzerland were now formally recognized as independent. In Germany the house of Hapsburg was no longer in a position of undisputed supremacy; the houses of Hohenzollern, Saxony, and Wittelsbach had all gained in importance; and, instead of a powerful kingdom, there was nothing but a "lax confederation of states." The authority of Spain was still acknowledged in Naples and Sicily, in Milan and Sardinia, as well as in the Catholic portion of the Netherlands. Venice was the principal native power in the north of Italy, and a large part of the central region was in the hands of the church. France had increased her territory by the acquisition of Alsace, and was the most formidable military state in the continent. The three kingdoms of the English crown had for some time been united under a common dynasty. Russia was recovering her position; Poland was already beginning to decline; the Turkish power was losing ground before the Germans and Hungarians, and, as a natural consequence, the Hungarian kingdom was gathering strength.

The rest of the 17th century was mainly remarkable for the series of wars with which the name of Louis XIV. of France is more immediately associated. They produced in the long run comparatively small alterations in the partitioning of territory, as the treaty of Ryswick was in the main an instrument of restoration. Of much greater effect was the death of Charles II. of Spain in 1700, followed as it was by the war of the Spanish succession, in which all the principal states were more or less embroiled.

At the close of the contest the Bourbons of France got possession of Spain, Sicily, and Parma; the Austrian branch of the house of Hapsburg obtained the Spanish Netherlands, Naples, Sicily, and Milan; the Prussian kingdom of the Hohenzollerns was formally recognized and its territory increased; the duke of Savoy became king of Sardinia; and England secured the occupation of Gibraltar and Minorca. The principal effect of the wonderful campaigns of Charles XII. of Sweden was to leave his country in a condition so exhausted that, at the peace of 1720–1, it had to give up a great part of what it had acquired during the 17th century. A totally different result attended the equally daring but more politic enterprises of Frederick the Great, who greatly increased his territory and secured for his kingdom a brilliant future in Europe. About the same time, under Peter the Great, Russia was making conquests both in south and north, and was preparing to take her place side by side with the Western powers.

In the latter half of the 18th century, or, more, precisely, about the year 1785, the political map presented the following divisions. The German empire under Joseph II. extended over an area of about 255,120 square miles, had a population of upwards of 26,000,000, and consisted of no fewer than 289 states, of which 61 were free cities. The portion of the Austrian possessions which was not included in the empire had an area of 152,000 square miles, and a population of 9,250,000; and the corresponding portion of Prussia had an area of 29,764 square miles, and a population of 1,500,000. To France, at that time under Louis XVI., belonged no less than 201,970 square miles, and a population of 26,000,000. The inhabitants of Great Britain and Ireland numbered no more than 12,000,000; and Spain, with her area of 195,600 square miles, had only about 10,500,000. Italy was broken up among eleven states, and her total population was estimated at 16,250,000. The kingdom of the Two Sicilies included the island of Sicily and all the southern portion of the peninsula as far north as Terracina in the west and Ascoli in the east; to the north lay the States of the Church, extending in the east to the mouth of the Po, and in the west to the borders of Tuscany; Tuscany in its turn was conterminous with the territory of Lucca and the duchy of Modena; to the west of Modena lay the territory of Genoa and the duchy of Parma; the duchy of Milan stretched along the northern half of the valley of the Po from Lucarno to Mirandola; the kingdom of Sardinia included Savoy and all the country westwards to the frontiers of Switzerland and France; and the republic of Venice stretched its authority from Lucca in the west to Aquileia in the east, as well as along the Dalmatian coast to the neighborhood of the Narenta. The republic of the United Netherlands had 7290 square miles of territory, and 2,250,000 of a population. Norway was politically united with Denmark; and the king of Denmark, Christian VII., consequently held sway over an area of 165,830 square miles, and a population of 2,250,000. The Swedish territory was about 233,860 square miles, but the population was only 3,000,000. Switzerland occupied 14,880, with 1,750,000 inhabitants. The republic of Poland, in spite of the partition of 1772, by which it lost 6600 square miles, still possessed a territory of upwards of 223,000 square miles, and a population of about 14,000,000. Russia held 1,593,300 square miles, and Turkey about 245,000; and their respective populations amounted to 25,000,000 and 15,000,000.[1]

In 1789 the great French Revolution had fairly commenced, and for the next quarter of a century the history of Europe is little more than a history of France and her friends, and France and her foes. Never since the invasions of the Germanic nations had there been such a complete overturning of all existing political arrangements as was effected by the daring despotism of Napoleon. In 1812 the French empire included, not only France, Belgium, Holland, and Luxembourg, but also the whole country to the left of the Rhine, the mainland of Sardinia, part of Modena, Tuscany, and Rome, Geneva, Neufchatel, and Valais—a total area of no less than 339,000 square miles, with an aggregate population of 42,366,000. The 35 states of the confederation of the Rhine, including the kingdoms of Westphalia, Saxony, Bavaria, Würtemberg, the grand duchies of Frankfort, Berg, Baden, Hesse, and Wurzburg, were under the protection of Napoleon; a similar position was held by the kingdoms of Italy and Naples, by Illyria and the grand duchy of Warsaw; and French influence was paramount in Switzerland, Prussia, Austria, and Denmark. England and Russia were the only truly independent states of real political importance; Spain and Portugal were fighting for their existence; and Sweden on the one hand, and Turkey on the other, were practically outside of Europe.

At the great monarchical congress of Vienna an attempt was made to restore nearly everything that the Revolution had undone. Austria recovered East Galicia from Russia, and Tyrol and Salzburg from Bavaria; and in compensation for Belgium, etc., she obtained the Lombardo-Venetian kingdom of Italy, as well as Dalmatia and Parma. A kingdom of the Netherlands was constructed out of Belgium, Holland, and the German duchy of Luxembourg. The kingdom of Sardinia was restored to Victor Emmanuel and strengthened by the addition of Genoa; and Modena and Tuscany were assigned the one to Duke Francis IV. and the other to Ferdinand the brother of the Austrian emperor. Naples and Sicily, as the kingdom of the Two Sicilies, were given back to the former king Ferdinand; Spain and Portugal to Ferdinand VII. and the house of Braganza respectively. Russia incorporated Finland, Bessarabia, part of Moldavia, etc.; the kingdom of Poland was governed under Russian suzerainty by a vice-king, with a free constitution; Cracow was declared a free state under the protection of Austria, Russia, and Prussia. Switzerland was allowed to retain its federative system, and its neutrality was guaranteed. Prussia not only got what she had lost by the peace of Tilsit, but received a part of Poland, including Dantzic and Posen, the half of the kingdom of Saxony, and a flourishing territory on the middle and lower Rhine; Bavaria obtained the Palatinate of the Rhine; and Hanover, augmented by East Frisia, was made a kingdom. The restoration of a German empire being rendered impracticable by the particularist tendencies of several of the larger states, a German confederation, or Deutsches Bund, was substituted, under the presidency of Francis of Austria and his successors. The diet of this confederation had its seat at Frankfort-on-the-Maine, and consisted of the representatives of no fewer than 38 sovereign states, which, besides the Germain dominion of Austria, included the five kingdoms of Prussia, Bavaria, Hanover, Saxony, and Würtemberg, the electoral principality of Hesse-Cassel, seven grand-duchies, nine duchies, ten principalities, the landgravate of Hesse-Homburg, and the four free cities, Frankfort, Hamburg, Bremen, and Lübeck. England obtained possession of Malta in the Mediterranean and of Heligoland off the Danish coast; and the Ionian islands were placed under an English protectorate.

And now a new glacial period of absolutism threatened to invade Europe. Alexander of Russia, Frederick William of Prussia, and Francis of Austria, united in a Holy Alliance, which, based perhaps honestly enough, on the noblest humanitarian professions, proved practically an association for the strict preservation of the royal prerogative against the encroachments of the people. The promise of constitutional government made by many of the sovereigns to their subjects was forgotten or ignored, and even when a constitution was granted it was not unfrequently another form of despotic machinery. The Bourbons bourbonized in France and Spain, and the policy of Metternich was dominant in Austria and Italy. The pope did his best to restore the supremacy of the clergy by concordats with the several states of Catholic Europe; the Jesuits were re-established, and soon recovered a large part of their influence; and even the Knights of St. John were called back to a futile existence.

But the principles of the Revolution were not dead; they only slumbered, and before long they gave signs of awaking. Neither the political distribution of the European territory established by the Congress of Vienna, nor the political doctrines which mainly conditioned the distribution, were destined to endure. The July revolution in France (1830), which drove out Charles X. and introduced the constitutional government of Louis Philippe, was a signal of change. In the same year the independence of Greece was permanently secured, after the treaty of Adrianople had closed the Russo-Turkish war; and the separation of Belgium from Holland was recognized by the five great powers in the London conference. A great struggle for national existence burst out in Poland—only, however, to end in its complete incorporation with Russia. By 1848 constitutionalism had made no small progress; Russia, Austria, and Prussia were, indeed, as absolutist as ever, but, besides England, France, and Switzerland, Spain and Portugal, Holland and Belgium, Norway and Sweden, Denmark, Greece and the greater number of the minor German states, had all attained a certain amount of political freedom. In Germany, Duke Charles Augustus of Saxe-Weimar had given his subjects a constitution as early as 1816; Nassau, Bavaria, and Baden followed the example in 1818; and after violent disturbances the people of Würtemberg secured the same privileges. If the July revolution of 1830 had been potent, much more potent was the more radical revolution of February, 1848. The storm swept over the Continent, and when it had ceased the political aspect of Europe had changed. By the dreadful "Days of March," the king of Prussia, Frederick William IV., was forced to become a "constitutional king," and a national assembly was soon after instituted. In Austria, Metternich had to flee for his life, and Ferdinand was constrained to submit to the demands of the Liberals. In Italy, Rome expelled the pope and declared itself a republic; Sicily expelled the Bourbons and chose the duke of Genoa as their king; and the northern states rose against Austrian domination. A reaction, however, soon again set in. France passed from a republican to a strongly monarchical government; the Prussian king cancelled his constitution and issued another in its stead; Austria was successful in putting down the Hungarian and Bohemian patriots and inflicting a terrible revenge; and Italy saw the defeat of the army of Charles Albert, and had to submit again to Austrian despotism in Lombardy, papal despotism in Rome, and Bourbon despotism in Sicily and Naples. The hope of a real German unity based on constitutional principles which had been raised by the great Frankfort parliament, died away; Austria was still in the ascendant, and under her countenance and support all liberal movements were violently suppressed in the south German states. The first great disturbance of the sullen and sultry peace which settled down over Europe was occasioned by the claim of Russia to the protectorate of the Greek Christians in the Turkish empire, and her invasion of the Danubian principalities. England and France determined to maintain the integrity of Turkey, and the Crimean war was the result. By the treaty of Paris, which closed the contest (March, 1856), Russia ceded a small piece of territory to the north of the Danube, the navigation of the river was declared free, Moldavia and Wallachia were increased by the addition of the Russian surrender and placed along with Servia under the protection of the contracting powers, and the neutrality of the Black Sea was established. The real power of Turkey was hardly increased; and in 1859 she had to utter useless protests against the principalities of Wallachia and Moldavia, which united into one under the name of Roumania, and chose Alexander Cusa, a Moldavian nobleman, as their chief. The Italian kingdom of Sardinia, which had joined in the Crimean war as an ally of England and France, was soon to play a much more brilliant part in Europe. With the powerful assistance of France it drove Austria out of Lombardy, and practically secured the leadership among the states of Italy. In 1860 the first Italian parliament contained representatives, not only of Sardinia and Lombardy, but also of Tuscany, Modena, Parma, and the Roman Legations, all these states having voted by general suffrage to cast in their lot with Sardinia. The same year saw the marvellous campaigns of Garibaldi; and on the 17th March, 1861, Victor Emmanuel was recognized as king of Italy by all the Italian states except Austrian Venetia and the city of Rome. In 1864 another important alteration of political boundaries was effected in the north. The provinces of Schleswig-Holstein, occupied by a partly Danish and partly German population, were conquered by the united forces of the German confederation. Before long it was evident that Prussia meant to appropriate them to herself as of great service to the development of her marine. By the Gastein convention of 1865 it was arranged that the government of Schleswig should fall to Prussia and that of Holstein to Austria, while Lauenburg was yielded to Prussia for 2½ millions of Danish rixdollars. This treaty, however, proved only a very temporary settlement,—the real question at issue being whether Prussia or Austria was to be the dominant power in Germany. The diet, which, according to the treaty of Vienna, ought to have been arbiter between them, was too weak to give effect to any decision: it sided with Austria, and mobilized its army by the decree of 14th July. By 3d July, 1866, the fate of Germany was decided by the battle of Königgrätz or Sadowa, and on the 23d of August the treaty of Prague was signed. The Austrians ceded the Venetian territory to the Italians (who had naturally seized the opportunity of the war), gave up their claim to Schleswig-Holstein, and promised to recognize the German confederation and any territorial changes effected within its limits. In 1866–67 the confederation was constituted, under the direction of Prussia, to include all the German states to the north of the Maine; they were to have one common federal legislation and a federal army, while in everything Prussia was to have the pre-eminence. The duchy of Luxembourg in the same years threatened to involve Europe in a new war, as Prussia refused to permit its transfer by the king of Holland to the French emperor; but peace was secured by a conference of the great powers in London (May, 1867), who guaranteed the neutrality of the territory and secured the dismantling of its fortresses.

---

[1] See Kolb, *Handbuch der Statistik.*

Another step in the unification of Germany was taken in 1868 by the reconstruction of the Zollverein or customs union. Meanwhile Austria had been turning her attention to her domestic difficulties, and had settled the most important by the recognition of the autonomy of Hungary, which was henceforth to be associated with Austria proper on equal terms. In June, 1867, Francis Joseph and his consort were formally crowned at Pesth as king and queen of Hungary. The year 1870 saw the completion of Italian unity by the occupation and annexation of the city of Rome, and, what was of still greater consequence to Europe at large, the rise of a dispute between France and Prussia about the succession to the throne of Spain. The matter was of little real moment to either, but the French Government was eager for the fray, and Prussia was not slow to take up the gage. If the strength of the two combatants be considered, the terrible conflict was soon over. The German troops, who had crossed the frontier in August, 1870, entered Paris in March, 1871; the preliminary peace had been signed at Versailles in February; and the final peace was concluded 10th May. Prussia's position in Germany and Europe was established, and her king had been recognized as emperor of the German confederation on 18th June, in the palace of Versailles. Europe again enjoyed peace for a few years; but in 1877 Russia declared war against Turkey, ostensibly as protector of the Christian populations who were suffering from the anarchy of her government. In Europe and Armenia the conflict continued with growing success on the part of the Russians till the preliminary peace of San Stefano. The alterations demanded by Russia were of the most sweeping kind, and would practically have removed Turkey from the rank of a European power, as the territory to be left under her control was both of small extent and discontinuous. The conclusion of the treaty on such conditions was strongly opposed by the British Government, and for a time it almost appeared as if Europe were to be involved in a far more terrible war than that which had come to a close. After much political finessing it was at length decided that the matter in dispute should be submitted to an international congress, and the plenipotentiaries of the various powers accordingly met at Berlin on Thursday, 13th June, 1878.

Rise of the present territorial divisions.

Such in the most meagre outline are the principal changes in the political distribution of the territory of Europe. A clearer idea of the rise of the several powers of the present time may be obtained from the following equally rapid survey.

Great Britain began in the little Saxon kingdom of Wessex, which, according to the usual account, dates from Cerdic's settlement in 519 A.D., and by 880 had extended its authority as far north as the Forth and Clyde. The remoter portions of this territory afterwards gravitated now to England and now to Scotland, till at last the boundaries between the two kingdoms became what they still remain. Wales was subjugated by Edward I. in 1282; and the conquest of Ireland, begun in 1169 under Henry II., was completed by 1610. The English and Scottish crowns were united on the accession of James of Scotland to the English throne in 1603, and the two countries became politically one by the Act of Union in 1707. The representation of Ireland in the English parliament dates only from 1801.

France practically had its commencement when Hugh

Capet united the duchy of Francia with the minor territories still left in the hands of the petty Carolingian kings, and established the capital at Paris. Its subsequent growth was very gradual, and the successive additions were obtained partly by conquest, partly by purchase, and partly by matrimonial alliances. Philip I. bought the duchy of Berri; Philip Augustus secured possession of Anjou, Maine, Touraine, and Poitou, and of Normandy, Vermandois, Alençon, Auvergne, and Evreux; St. Louis obliged the count of Toulouse not only to give up part of his territory, but also to recognize the reversionary rights of the crown; Philip IV. added the countship of Lyonnais, and John incorporated Champagne and Brie. With the accession of the house of Valois the duchy of that name naturally became part of the royal domain, and shortly afterwards Dauphiné was obtained from the childless Hubert II. The long English wars interrupted the advance and dismembered the kingdom, and it was not till 1450 that the king of France was again in possession of his full inheritance. In 1477 the great duchy of Burgundy was incorporated with the crown; Provence, the Boulonnais, and Picardy were all acquired in 1481; and in 1488 the death of the last duke of Brittany paved the way for the incorporation of his duchy. Henry IV. brought part of Navarre, Bearn, and Foix; Louis XIII. united Artois with the crown; and Louis XIV. secured not only the greater part of Alsace, but also French Flanders, and Franche Comté. Corsica, which had been conquered from Genoa in 1768, and Avignon and the Venaissin, which had been held by the popes, were incorporated in 1791.

Austria was originally a *mark* established by Charles the Great for the defence of Bavaria against the Avars. It was made a duchy by Frederick Barbarossa in 1156, and in 1192 was increased by the addition of Styria. The acquisition of Carinthia, Tyrol, and Trieste took place in the 14th century; and in 1453 the duchy was made an archduchy by the emperor Frederick. Dalmatia was gained by the treaty of Cambray in 1508; Hungary, Bohemia, and Silesia by the marriage of the archduke Ferdinand, the brother of Charles V., with the Hungarian princess in 1526; Galicia and Lodomeria at the partition of Poland in 1772; and Bukovina from Turkey in 1778.

The present German empire dates, as has been seen, only from 1872. Prussia, conquered from the pagan Slavonians by the Teutonic knights of the 13th century, was in 1525 granted by the Polish king Sigismund I. as an hereditary duchy to Albert of Brandenberg, and in 1611 became independent of the Polish crown. In 1701 Duke Frederick was permitted by the emperor to assume the title of king of Prussia; and under his grandson Frederick the Great the territory of the new kingdom was increased by Silesia and large parts of Poland. In 1866 Hanover, Hesse-Cassel, Nassau, and Frankfort were annexed.

The battle of Morgarten in 1315 secured the independence of the Forest Cantons of Switzerland; and in 1352 the first real confederation was formed by Schwyz, Uri, Unterwalden, Lucerne, Zurich, Glarus, Zug, and Bern. Aargau or Argovia and Thurgau or Thurgovia were annexed in 1415, and Ticino or Tessin in 1418. Soleure or Solothurn and Freiburg or Fribourg joined the confederacy in 1481, Basel and Schaffhausen in 1501, and Appenzell in 1513; St. Gall, Geneva, Neufchatel or Neuenburg, Valais or Wallis, and the Grisons or Graubünden shortly afterwards became associated states; and in 1536 Vaud or Waadt was conquered from the dukes of Savoy.

The kingdom of Spain was formed by the union of Castile and Aragon in 1479. Castile had become a kingdom in 1033, and had successively incorporated Toledo, Leon, and Galicia; and Aragon, which represented the older kingdom of Sobrarve, had gradually got possession of Catalonia and the countship of Barcelona, Valencia, Majorca, Minorca, and Iviça. The conquest of Granada in 1492 and of Navarre in 1512 completed the territorial extension. Portugal, which has more than once been incorporated with Spain, was erected into a kingdom in 1139.

The beginnings of the Russian empire are usually traced to a body of Scandinavian adventurers in the 9th century, but the real commencement of the present monarchy is the grand duchy of Moscow, which, in the 14th century, under Ivan Kalita, began to be paramount among the various Russian principalities. During the next 200 years these were gradually subdued, the last and greatest of all, Novgorod, being incorporated in 1478. In 1654 the chief of the Zaporogian Cossacks recognized the Russian supremacy, and Smolensk and part of White Russia were annexed. In 1721 Livonia, Esthonia, Ingermanland, and part of Finland were ceded by Sweden; in 1742 another part of Finland was added; in 1772 the northern and eastern portions of White Russia, and in 1774 Azoff, Kertch, Yenikale, and Kinburn. The whole of the Crimea was incorporated in 1783, and ten years after, Volhynia, Podolia, and the government of Minsk. The year 1795 saw the annexation of Lithuania, Courland, and Samogitia, and the first decade of the 19th century the successive incorporation of Georgia, Mingrelia, and the remainder of Finland. Imeritia was added in 1810, Bessarabia in 1812, and the duchy of Warsaw in 1815; and the conquest of the Caucasian region was completed in 1859–1864.

The Scandinavian kingdoms date from the 8th and 9th centuries; and their territory has been at various periods very differently distributed among themselves. An amalgamation was effected by the union of Calmar in 1397, and lasted till 1524. The present union of Norway and Sweden dates from the treaty of Kiel in 1814.

General tendencies.

To no man, however vast his experience and varied his sympathies, is it granted to form even an approximate estimate of all the multitudinous forces that are at work within the limits of a single country, and still less is it possible to form such an estimate if the field of observation include the heterogeneous activities of such an area as Europe. The local current is apt to be taken for the general, and the recoil of the wave for the retreat of the tide. Still there are movements and tendencies which force themselves on the notice of even the superficial observer, about whose present potency there can be no question, whatever antagonistic tendencies may be secretly gathering strength below the surface or in the remoter parts of the area. Of several of these mention more or less distinct has already been made, but it may be well to attempt a more systematic survey.

Nationalism.

We have seen that nationalism is powerfully at work; the tendency to give practical application in the political domain to the principle familiarly expressed in the phrase *qui se ressemble s'assemble*, birds of a feather flock together. The so-called nations of Europe are still in painful process of formation,—some in one stage and some in another, but all without exception very imperfectly organized. As a mere vocable the word nation is old enough, but the thought which it not vaguely expresses is a thought that men are but beginning to think. Europe has had its tribes and its kingdoms, its village-communities, its cities, its Achæan leagues, its Hanseatic confederations, its republics, its empires; it is only developing its nations. Hence in part the difficulty of attaining a satisfactory definition of nationality; and hence the endless collisions and confusions that arise in the practical application of the principle. If all people of the same blood spoke the same language, held the same religion, and occupied continuous territory, the whole question would be solved. But, as has been seen, this is as far as possible from being the case in Europe; and neither blood, nor language, nor religion, nor continuity of territory can be accepted as master of the practical arrangement. The principle of nationalism has consequently to work by compromise. It sometimes appears as a restorative and conservative, sometimes as an innovating and creative force; and any attempt to insist that it shall be exclusively this or that is certain to be abortive. Here it is on the side of the weak and oppressed, and seems humane and benign; there on the side of the strong and despotic, and seems stern and cruel. In spite of all difficulties and opposition it is making rapid progress, and is likely to be a powerful factor in Europe for generations to come,—building up political unities, rehabilitating decadent languages, and calling new literatures into life. Greece and Italy, Belgium and Bohemia, Hungary and Roumania, are testimonies of its power in the past decades of the century: who will say what it will have accomplished before the century is done?

Internationalism.

As a natural complement of nationalism we have internationalism, which in certain aspects may be regarded as a stage in the progress to cosmopolitanism. Just in proportion as the various nations develop and recognize their national individuality they become conscious of their true relations to each other, and find the necessity of regulating their mutual intercourse and common activity; isolation is impossible. Reciprocity must increase with the capacities and desires of each: there are many things which can be attained only by concerted action or division of labor. The tendency of internationalism is displayed in the purely political domain by the growth of international law, and the gradual endeavors after a system by which international disputes may be settled by arbitration and discussion rather than by armaments and devastation. That it will end before long in something like a confederation of European states the optimist believes and the philanthropist hopes. Every European congress familiarizes the idea and establishes the habit. In the social domain the tendency is equally potent. Facilities of travel and accumulation of wealth are annually leading a greater proportion of the citizens of one country to make personal acquaintance with the citizens of another. Ignorance and bigotry are naturally lessened, though there are indeed an ignorance and a bigotry which return from abroad only more ignorant and bigoted than before. It needs no special insight to recognize the importance to the great progress of the world of such an innovation as the railway; but it would require more than human grasp of intellect to estimate the enormous extent and complexity of its influence. It is the one touch of art which will make the whole world kin. As a mighty upheaval lifts an archipelago of islands into a continent, so is this one power heaving Europe into unity. The movement is perhaps most noticeable in matters of little intrinsic importance, as in the gradual dying out of national and provincial costumes before the invasions of Parisian taste: but to the philanthropist nothing can be uninteresting that either indicates or accelerates the advance. In literature and art we have a still more important development of internationalism; for it was in this domain that it first made itself powerfully felt. Though Spain, France, England, Germany, and Holland have each given birth to distinct schools of painting, the influence of Italy has been paramount from the beginning; and though the literatures of the several countries are distinguished from each other by much that is characteristically local and national, they have all been based more or less directly on the classical work of Greece and Rome, and undergone continual modifications from their mutual interaction. It is hard to conceive what would have been the progress of English literature apart from the influence of Dante and Boccaccio, or, in later times, the progress of French literature if Voltaire and his contemporaries had received no inspiration from this side the Channel. To write the history of any literature is impossible if no account is taken of its foreign indebtedness. This mutual interaction is rapidly increasing, and in spite of the recent additions to the number of distinct literary areas, it is imprinting more and more of a common character on the whole. The novels of a Scott or the poems of a Byron sweep over the Continent, and come back in manifold reverberations from Germany and France, from Sweden and Spain. If the phrase the republic of letters is appropriate, still more appropriate is the republic of science; if literature is becoming international, science is international. However bitter the jealousies that may separate France and Germany, the French savant watches eagerly for the work of his German compeer, and the German cannot afford to disdain the contributions of the Frenchman. International congresses of the representatives of particular departments of research are becoming mere matters of course; a meteorological congress met at Vienna in 1868, a health congress at Brussels in 1877. An association ultimately joined by nearly all the Continental nations was formed at Berlin in 1866 to determine the meridian between Palermo and Christiania, and thus furnish a standard unit for Europe; and in 1877 a geographical congress for the exploration of Africa was opened under the presidency of the king of the Belgians. How necessary such co-operation really is is shown by the loss that science has already sustained from the existence of different methods of registration and observation: the labor of years has not unfrequently been rendered utterly useless to the general progress by the employment of incommensurable systems. Considerable advances have happily been made towards the universal adoption of the same metrical and monetary standards. The French system of weights and measures was introduced into the Netherlands in 1820, into Spain in 1859, into Portugal in 1868, into Germany in 1872, and into Roumania in 1876. In 1881 it will become obligatory in Norway and Sweden. A monetary league, by which they agreed to perfect reciprocity of currency, was formed in 1865 by France, Italy, Belgium, and Switzerland, and they were joined by Greece in 1875, and by Roumania in 1876. Uniformity of coinage was established throughout the German empire in 1872, and in 1875 the Scandinavian states agreed to adopt a common system. In 1874 a postal union was constituted by a convention at Bern between Austria-Hungary, Belgium, Denmark, France, Germany, Great Britain, Greece, Italy, Luxembourg, the Netherlands, Norway, Portugal, Roumania, Russia, Servia, Spain, Sweden, Switzerland, and Turkey; and this has been followed by a similar telegraphic union.

Toleration.

A third tendency fostered by the same conditions as internationalism is what is known as religious and political toleration. The name is an unhappy one, as it implies the mutual obnoxiousness of the various religious and political parties, but the time has hardly come when it can be considered a misnomer; the foremost countries of Europe are still far from having attained the full enjoyment of that intellectual liberty which formed the ideal of a Milton, a De Tocqueville, or a Stuart Mill. Thanks, indeed, to the influence of the French Revolution, rapid progress has been made during the present century, and the severer forms of persecution have fallen decidedly out of fashion. The Jews are the most notable monument of the change. Their history for centuries was full of blood and tears; they were despised and rejected; their very name was a byword and reproach. The 19th century has seen them gradually admitted to all the rights of citizens in the most flourishing countries of the continent, guiding the destinies of nations and mingling their blood with the proudest nobilities. In the more backward and conservative countries they still labor under many disadvantages; from Norway and Russia Proper they are excluded by law, and in Portugal and Spain they are emphatically aliens. The same number of Dr. Lehman's *Der Israelit*, one of the organs of the orthodox party, reports that Roumania is preparing a law for the civic and political equalization of the native Jews, and that in Bulgaria the hatred against the Jews is so great that, on the evacuation of Rustchuk by the Turks, the Bulgarians sent a deputation requesting the Russian commander to expel the whole Jewish community and to plunder their shops. The liberal movement of Roumania was dictated partly by a desire to obtain the sympathy of Western Europe; for until recently persecution of the Jews was carried on as vigorously there as in the neighboring countries. Between Roman Catholics and Protestants the ancient feud has lost some of its bitterness. In Scotland and England the legal emancipation of the Catholics in 1829 has been followed by social changes of great importance, the extent of which may be estimated by the little opposition which was offered to the restoration of the Roman Catholic hierarchy in Scotland in 1878. In Prussia and throughout the German empire there has been a recrudescence of animosity between the confessions; but it is to be observed that the contest is rather between the state and a political party than between the Catholics as Catholics and the Protestants as Protestants. In fact, it is only part of a wider contest which is being fought under varying forms throughout the greater part of Europe, as to whether the state or the church is to be the dominant power. Many of the measures which the Government has adopted have certainly led to what is practically religious persecution; but this persecution is totally different in its character from the persecutions of the Huguenots in the 17th century. The most extreme exertions of power have been the suppression of religious communities, the removal and appointment of priests and bishops by the civil authorities, the prohibition of religious processions, and in 1876 the closing of all Catholic schools and the assertion of complete state control over all church property. In Switzerland the movement was similar; the Old Catholic party was recognized by the state in 1875, and the cathedrals of Bern and Geneva handed over to its clergy. In Belgium the Liberal and Protestant minority have excited violent disturbances in several cities, as Ghent and Brussels, and the social fermentation has been carried to dangerous extremes; but by the constitution there is full religious liberty, all the churches are subsidized by the Government, and by a curious anomaly the heaviest subsidy is paid to the weakest denomination. The relations established between Italy and the Pope, by the absolute irreconcilability of their territorial claims, has naturally led the Italian Government to adopt a strongly anti-ecclesiastical policy: the state religion is Roman Catholicism, but the suppression of monasteries has been vigorously carried out, and religious processions outside of the churches can only take place by special permission of the prefects. The constitution sanctions full religious liberty. In France Roman Catholics, Protestants, and Jews all receive grants from the public treasury. The Russian Government exercises its authority in favor of the Greek church in a way that frequently infringes on the liberties of other religionists, and no secession can take place from the pale of the establishment; but at the same time the profession of any creed is legally allowed. Spain, by the last of her many revolutions, has taken a step backwards: private worship is still permitted to non-Catholic religions, and foreigners are considered inviolable, but all public manifestations, by printed notices, emblems, or otherwise, are strictly prohibited.

Humanitarianism.

It has happily become impossible for even the most retrograde of nations to recall the days of the Inquisition,—a fact that is at least partly due to the influence of another great movement, which may be distinguished as humanitarianism. This movement is evident in so many departments of thought and action, here introducing a less painful process of killing into the slaughter-house, and there affecting the decision of questions of speculative theology, that only a few suggestive facts need be mentioned. The penal codes of all European nations have been cleared of most of their mediæval barbarism; and the infliction of direct physical suffering is reserved for the more brutal class of criminals. Instruments of torture are mere antiquarian curiosities. The punishment of death, once the common penalty for trivial and heinous offences, already appears to many minds as altogether inhuman, and has been completely abolished or discontinued in Holland, Belgium, Portugal, Switzerland, and Roumania. The bill for its abolition in Italy in 1875 was lost by 73 to 36, and the district of Tuscany, which had adopted the abolition about twenty years before, was forced to conform to the general law. In 1876, however, the committee for the revision of the penal code unanimously voted for the abolition. The introduction of private instead of public executions is a step in the same direction, though like many other partial measures it may delay the complete disuse of capital punishment. Mention may also be made of the amelioration of prison discipline, of the magnificent progress in the treatment of the insane which has been effected by the philanthropists of the last two generations, of the enormous increase which has taken place in the number of our hospitals, asylums, and benevolent institutions, and of the growing attention that is paid to relief of the sufferings of the lower animals. Whatever be the wisdom of the measure, the law of 1876 in England in regard to vivisection speaks volumes for the advance of the humanitarian movement. In this respect as in others the various European nations are in very different stages: while the English magistrate is fining a collier or carter for lending his countenance to a cockfight, the Spanish magistrate is applauding the exploits of a *picador* or *matador*. That we are approximating to a unity of sentiment is shown among other things by the support which has been given to the Geneva convention for the mitigation of the sufferings of the wounded in war, which was formed in 1864 by the representatives of Baden, Belgium, Denmark, France, Hesse, Italy, the Netherlands, Prussia, Switzerland, and Würtemberg, and which has since obtained the adhesion of Greece, Great Britain, and Turkey.

EURYDICE. See ORPHEUS.

EURYMEDON, an Athenian general, who, in the 5th year of the Peloponnesian war, 428 B.C., was sent by the Athenians, with a fleet of 60 vessels, to intercept the Peloponnesian fleet which was sailing to attack Corcyra, at that time rendered defenceless through internal feuds. On his arrival he found that Nicostratus with a small squadron from Naupactus had placed the island in security, but he took the command of the combined fleet, which, however, the absence of the enemy prevented from achieving any other end than merely to countenance and support by its presence the cruelties inflicted by the democratic party on their political opponents. In the following summer, in joint command along with Hipponicus of the land forces of the Athenians, he, in concert with the fleet commanded by Nicias, ravaged the district of Tanagra; and in 425 B.C., conjointly with Sophocles, he was sent in command of an expedition destined for Sicily. After leaving, they learned that the enemy's fleet was at Corcyra, but they were delayed by stormy weather from arriving there in time to attack them. They had been commanded in any case to touch at Corcyra, in order to deliver the democratic party from the attacks of the oligarchical exiles, who had taken up a position on a hill near the city, and were threatening it with capture. On the arrival of the Athenian fleet the oligarchical leaders surrendered themselves on condition that they should be sent to Athens to be judged; but they were treacherously induced to make an attempt to escape, and on that account were delivered up to the fury of their opponents. Eurymedon then proceeded to Sicily, but immediately on his arrival there a pacification was concluded by Hermocrates, to which Eurymedon and Sophocles were induced to agree. The terms of the pacification did not, however, satisfy the Athenians, who attributed its conclusion to bribery, and punished two of the chief agents in the negotiation by banishment, while Eurymedon was sentenced to pay a heavy fine. In 414 Eurymedon, sent with Demosthenes to reinforce the Athenians at the siege of Syracuse, was defeated and slain in the first of two battles fought before its walls.

EURYSTHEUS. See HERCULES.

EUSEBIUS, of Cæsarea, surnamed Pamphili, *i.e.*, the friend of Pamphilus, and well known as the father of ecclesiastical history, was born probably in Palestine about the year 265. The date of his birth is, however, uncertain, and varies between 260 and 270. We know little of his youth beyond the fact that he was a diligent student of sacred literature, his biography by his episcopal successor Acacius having perished. It was as a student, and probably as holding some inferior office in the church at Cæsarea, that he became connected with Pamphilus, who was at the head of a theological school there, and devoted himself to the collection of a church library, especially to the care and defence of the writings of his great master Origen. In the course of the Diocletian persecution, which broke out in 303, Pamphilus was imprisoned for two years, and finally suffered martyrdom. During the time of his imprisonment (307–9) Eusebius distinguished himself by assiduous devotion to his friend, spent days with him in affectionate intercourse, and is supposed to have actively assisted him in the preparation of an apology for Origen's teaching, which survives in the Latin of Rufinus (Routh., *Reliq.*, iv. 339). After the death of Pamphilus Eusebius withdrew to Tyre, where he was kindly received by the Bishop Paulinus, and afterwards, while the Diocletian persecution still raged, went to Egypt, where he was imprisoned, but soon released. His release at the time suggested an accusation made against him more than twenty years afterwards by Potamon, the fiery bishop of Heraclea, that he had apostatized. "Who art thou, Eusebius," exclaimed Potamon at the famous council of Tyre, which condemned Athanasius, "to judge the innocent Athanasius? Didst thou not sit with me in prison in the time of the tyrants? They plucked out my eye for my confession of the truth; thou camest forth unhurt. How didst thou escape?" The coarseness of the accusation, however, was only in the spirit of the times, and it rests on no evidence whatever. The elevation of Eusebius to the see of Cæsarea so soon afterwards, in 315 at latest—probably 313—is of itself sufficient to dispose of any such charge. Here Eusebius labored and became a conspicuous figure in the church till the year of his death, 340. The patriarchate of Antioch was put within his offer in 331, but he preferred the less eminent sphere associated with his early studies and friends, and as probably more congenial to his literary tastes and pursuits.

The character of Eusebius, both as a man and a theologian, is intimately bound up with the part which he took at the council of Nicæa, and afterwards in the great controversy connected with the work of that council. His conduct and his views have been differently judged, according to the estimate which later critics have formed of the merits of this controversy, and the dogmatic prejudices which on one side or the other it is apt to engender. Dr. Newman, for example, in his history of the Arians in the 4th century, speaks of him as "openly siding with the Arians, and sanctioning and sharing their deeds of violence," while most Anglican scholars, from Bull and Cave to Dr. Samuel Lee of Cambridge, who translated the *Theophania* of Eusebius in 1843 from a recently recovered Syriac MS., have warmly defended his orthodoxy. The same division of opinion regarding him has prevailed more or less in other quarters, and even in the age succeeding his own. It is only in the scientific theology of Germany, and especially in Dorner's great work on the *Person of Christ*, that his true theological position can be said to have been made clear. He was certainly not Arian, however he may have defended Arius personally, any more than he was Athanasian. He was really the representative of the indeterminate theology of the church on the great point in dispute, before the lines of controversy on the one side and the other had hardened into the formulæ which have become identified with the two positions known as Arianism and Athanasianism. To judge and still more to condemn him from one side or the other is to mistake the law of the historical development of dogma, and to apply to him conclusions which belong to a later type of thought than that in which he had been trained. This will be best seen by a brief explanation of his standpoint, both personal and theological, throughout the controversy.

When the Arian controversy broke forth, about 319, Arius, who possibly may have known something of Eusebius during his stay in Egypt, besought his intervention to pacify the misunderstanding between him and his bishop, Alexander. Eusebius responded so far as to write two letters to Alexander explaining that Arius was misrepresented (Fragm. in Mansi, xiii. 316). This fact is of interest, as showing his natural attitude in the controversy before the calling of the council of Nicæa. At this council he attended as the special friend of Constantine, whom he was appointed to receive with a panegyrical oration, and at whose right hand he enjoyed the honor of sitting. Not only so, but he prepared and submitted the first draft of the creed which was afterwards, with well-known and significant additions, adopted by the council. The whole difference between Eusebius and the Athanasians centred in these additions, and in fact in the famous expression "Homoousion"—"of the same substance"—which was judged necessary by the council to express the true relation of the Father and the Son. He resisted this expression to the last, and only at length accepted it and subscribed the creed at the dictation of the emperor. After the council he continued to identify himself with the fortunes of the Arian rather than of the Athanasian party, and his great favor at court and his influence with the imperial authorities enabled him to protect the one party at the expense of the other. It is this personal attitude which has mainly identified him with Arianism. In so far as he was a partisan, and lent himself to the persecution of the "orthodox" or Athanasians, the conduct of Eusebius is deserving of the censure that has been bestowed upon it. But it is to be remembered that from his own theological stand-point he was disposed to regard the treatment of Arius by his opponents as indefensible, and to consider his opinions as tenable within the church. In short the Athanasians were to him the innovators in doctrine rather than Arius, who only maintained a stand-point that many had held in the church before him, even if he restlessly drew unfounded conclusions from it, whereas the Athanasian development evidently appeared to Eusebius to go beyond the older and less determinate doctrine in which he had been trained. The special defect of Eusebius seems to have been a lack of that spiritual and speculative insight which sees the true drift of opinions, and detects below the surface of language a true from a false line of development of Christian thought. As Dorner says of the theological position at the time, it was clear that the church had arrived at a point at which it could not stand still, but must choose one or other of two courses,—either to take a step in advance and define the indefinite, or to go backwards either into heathenism or into Judaism.

The opinions of Eusebius himself may be summarized as follows. God is with him One, or the Monas, exalted in his supreme essence above all plurality. He is Being absolutely, *τὸ Ὄν*, or the primal substance, *ἡ πρώτη Οὐσία*. Thus essentially conceived, God is infinitely above the world, His relation to which is in and through the Son, "who is the image of the invisible, the first born of every creature" (Col. i. 15). He would have substituted the Greek of the latter expression, *πρωτοτοκος πάσης κτίσεως*, instead of the formula finally adopted in the Nicene creed, that the Son is *ὁμοούσιος τῷ πατρί*, "of the same substance with the Father." But in no sense did he recognize the Son as Himself a creature or as sprung like other creatures, *ἐξ οὐκ ὀντων*. He was not "the same as the Father, of equal power and glory," because the idea of the Divine is conceivably complete in God as One; but He was begotten of the Father before all worlds or æons. He was in a true sense *ἀνάρχρος*, "without beginning in time." Eusebius repudiated therefore the Arian formula, "There was a time when the Son was not;" he could even say, "the Son was always with the Father," *τῷ πατρί ὡς υἱὸν διὰ παντὸς συνόντα* (*Dem. Ev.*, 4, 8), yet he shrunk from calling the Son *συναΐδιος* or "co-eternal" with the Father. While holding, in short, in his own sense to the true divinity of the Son, he shrunk from attempting to define either with the Arians or the Athanasians the relation between the Father and the Son, as beyond human conception. The nearest image by which the relation could be conceived was that of *εὐωδία* (*Dem. Ev.* 4, 3), or the relation between a flower and its perfume. He seems to have preferred this to the image of light and its brightness, or "light of light,"—although both this phrase and the associated phrase "God of God" surviving in the Nicene creed were in the original "profession of faith" which he submitted to the council. From this brief statement it is evident that Eusebius was not himself doctrinally an Arian, however he may have favored the Arian party. He was separated from it on the essential point, that the Son was in no sense a creature or made, *ἐξ οὐκ ὀντων*. The name Exoucontian, by which the Arians came to be specifically known, could never have been applied to him. On the other hand, he is separated from the Athanasians chiefly by the two-fold conception of Deity, now as the semi-Platonic Monas or Ὄν, abiding in unapproachable self-existence, and now as the Divine Father self-revealing Himself in the Son, and in the world created by the Son. As his mind dwelt on the idea of Deity pure and simple, or as absolute Being, he seems to have recoiled from the identity of the Supreme God with the Logos; but as he dwelt on the idea of *the Divine in relation to the world*, he saw in the Logos or Son the full expression of the Divine—the organ or power through whom all created existence is called into being. There is, in other words, with him a "sensus eminens" in which God is One, alone in power and glory; but the Christian or revealed conception of God is nevertheless acknowledged by him as Trinitarian. According to Dorner's explanation of the Eusebian theology, "God's being a Trinity depends *on His will*. At the same time this does not mean that God might be other than Trinitarian, for it is impossible to God not to will the perfect."

These views of Eusebius are chiefly contained in his well-known *Demonstratio Evangelica*, in the first book of his lately discovered treatise on the *Theophania*, and in his treatise against Marcellus, who in extreme reaction from Arianism taught a doctrine approaching Sabellianism.

It only remains further to add that Eusebius is undoubtedly more of a writer and critic than of a thinker. He is admitted to have excelled in mere erudition all the church fathers, hardly excepting Origen and Jerome. But his writings are arid and artificial in style, with an air of compilation rather than of original power. His *Ecclesiastical History* is destitute of method or graphic interest of any kind, but is a valuable repertory of the opinions of the Christian writers of the 2d or 3d century, whose works have otherwise perished. It has been charged with personality and inaccuracy by Gibbon, but without adequate evidence. (See general estimate of Eusebius as an historian, article Church History, vol. v., p. 668.) The personal relations of Eusebius to Constantine have been, like other points of his life, variously judged. He was undoubtedly more of a courtier than was becoming in a Christian bishop, and in his *Life of Constantine* has written an extravagant panegyric rather than a biography of the emperor. Altogether he is a conspicuous and significant, rather than a great or noble figure in the history of the church.

Of Eusebius's works the most important are the following :—

1. The *Ecclesiastical History* in ten books,—comprising the history of the church from the ascension of Christ to the defeat and death of Licinius, 324 A.D. 2. The *Chronicon*, in two books,—comprising an historical sketch, with chronological tables, of the most important events in the history of the world from the days of Abraham till the twentieth year of the reign of Constantine. This work, which is one of great importance in the study of ancient history, was published in its complete form for the first time at Milan in 1818. 3. The *Præparatio Evangelica*, in fifteen books,—a collection of facts and quotations from the works of nearly all the philosophers of antiquity, intended to prepare the reader's mind for the acceptance of the Christian evidences. 4. The *Demonstratio Evangelica*, in twenty books, of which ten are extant,—a learned and valuable treatise on the evidences themselves. It is intended to complete the Christian argument for which the previous work was a preparation. In addition there are various minor works of Eusebius, viz., the *Theophania*, in four books, translated from a Syriac MS., discovered by Tattam in an Italian monastery in 1839; his treatises against Marcellus in two books, and against Hierocles; his life of Constantine—*De Vita Constantini;* and his *Onomasticon*, a description of the towns and places mentioned in Holy Scripture, arranged in alphabetical order. For accounts of Eusebius himself and his opinions, see Herzog's *Ency.*, s. voc.; Schaff, *Church Hist.*, ii. 872–9; Introd. to Lee's translation of the *Theophania*; Dorner's *Hist. of the person of Christ*, ii. 217, *et seq.*,—Translation in Clark's Foreign Theological Library. (J. T.)

EUSEBIUS, of Emesa, a learned ecclesiastic of the Greek church, was born at Edessa about the beginning of the 4th century. After receiving his early education in his native town, he studied theology at Cæsarea and Antioch, and philosophy and science at Alexandria. Among his teachers were Eusebius of Cæsarea and Patrophilus of Scythopolis. The reputation he acquired for learning and eloquence led to his being chosen in 341 by the synod of Antioch to succeed Athanasius as archbishop of Alexandria, an appointment which he, however, declined. He accepted instead the small bishopric of Emesa in Phœnicia, but on account of his reputation as an astrologist, the people opposed his settlement, and although they were ultimately induced, through the intervention of the bishop of Antioch, to receive him peacefully, he soon afterwards, either because of the discontent of his flock or on account of his love for a studious life, resigned his office and retired to Antioch. His fame as an astrologer commended him to the notice of the emperor Constantine, with whom he became a great favorite, and whom he accompanied on many of his expeditions. The theological sympathies of Eusebius were with the semi-Arian party, but he seems not to have had a very strong interest in the controversy. He has the reputation of having been a man of extraordinary learning, great eloquence, and considerable intellectual power, but of his numerous writings only a few fragments are now in existence.

EUSEBIUS of Nicomedia is the only other of the many early fathers or bishops of the church bearing the name who claims our notice. He was the defender of Arius in a still more avowed manner than his namesake of Cæsarea, and from him the Eusebian or middle party specially derived their name. He was known amongst them by the epithet of Great. He was a contemporary of the bishop of Cæsarea, and united with him in the enjoyment of the friendship and favor of the imperial family. He is said to have been connected by his mother with the emperor Julian. He was first bishop of Berytus (Beyrout) in Phœnicia, but his name is especially identified with the see of Nicomedia, which, from the time of Diocletian till Constantine established his court at Byzantium, was regarded as the capital of the Eastern empire. He warmly espoused the cause of Arius in his quarrel with his bishop Alexander, and wrote a letter in his defence to Paulinus, bishop of Tyre, which is preserved in the *Church History* of Theodoret. His views appear to have been identical with those of his namesake in placing Christ above all created beings, the only begotten of the Father, but in refusing to recognize Him to be "of the same substance" with the Father, who is alone in essence and absolute being.

At the council of Nicæa Eusebius of Nicomedia earnestly opposed, along with his namesake of Cæsarea, the insertion of the Homoousion clause, but after being defeated in his object he also signed the creed in his own sense of *ὁμοιος κατ' οὐσίαν*. He refused, however, to sign the anathema directed against the Arians, not, as he afterwards explained, because of his variance from the Athanasian theology, but "because he doubted whether Arius really held what the anathema imputed to him" (Sozom., ii. 15). After the council he continued zealously to espouse the Arian cause, and was so far carried away in his zeal against the Athanasians that he was temporarily banished from his see, and visited with the displeasure of the emperor as a disturber of the peace of the church. But his alienation from the court was of short duration. He retained the confidence of the emperor's sister Constantia, through whose special influence he is supposed to have been promoted to the see of Nicomedia, and by her favor he was restored to his position, and speedily acquired an ascendency over the mind of the emperor no less than that of his sister. He was selected to administer baptism to him in his last illness. There seems no doubt that Eusebius of Nicomedia was more of a politician than a theologian. He was certainly a partisan in the great controversary of his time, and is even credited (although on insufficient evidence) with having used disgraceful means to produre the deposition of Eustathius, the "orthodox" bishop of Antioch (Theodoret, i. 21). His restless ambition and love of power are not to be denied. To the last he defended Arius, and at the time of the latter's sudden death, 337, it was chiefly through his menace, as representing the emperor, that the church of Constantinople had been thrown into such anxiety as to whether the leader should be readmitted to the bosom of the church. Eusebius himself died in 342.

EUSTATHIUS, St., bishop of Berœa, was a native of Side in Pamphylia. By the council of Nice, in which he distinguished himself by his zeal against the Arians, he was promoted in 325 to the patriarchate of Antioch. So violent was the feeling among the Arians against him, that a synod of Arian prelates, convened at Antioch in 330, brought about his deposition on a charge of Sabellianism, as well as of various instances of unfaithfulness to his vows of celibacy. He was banished to Thrace, where he died probably in 359 or 360. Of several works attributed to Eustathius there is only one which can with certainty be pronounced his—an address, namely, to the emperor Constantine, delivered during the sitting of the council of Nice.

EUSTATHIUS, archbishop of Thessalonica, was a native of Constantinople, and flourished during the latter half of the 12th century. He was at first a monk, and afterwards teacher of rhetoric in his native city. In 1174 or 1175 he was chosen bishop of Myra in Lycia, and shortly afterwards archbishop of Thessalonica. Such of his works as have descended to our times display a comprehensiveness and variety of erudition that fairly entitle him to the praise of being the most learned man of his day. The most important of these is his *Commentary on the Iliad and Odyssey of Homer*, a work valuable as comprising large extracts from the scholia of other critics, whose works have now perished, such as Apion, Heliodorus, Aristarchus, Aristophanes of Byzantium, etc. This commentary was first published at Rome, 1542–50, in 4 vols., and was reprinted at Leipsic, in 1825–29, under the editorial care of G. Stallbaum. Eustathius also wrote a commentary on Dionysius the geographer, first printed by Robert Stephens in 1547, and frequently reprinted since. A commentary on Pindar, which he is known to have written, has been lost. He is also the author of various religious works, chiefly against the prevailing abuses of his time, which almost anticipate, though in a milder form, the denunciations of Luther. The year of Eustathius's death is uncertain, some placing it in 1194, and others a few years later. The funeral orations pronounced in his honor by Euthynius and Michael Choniates are still in MS. in the Bodleian library.

EUTERPE, the muse of lyric poetry. See MUSES.

EUTROPIUS, a Roman historian who lived in the latter half of the 4th century. Both his surname and the place of his birth are unknown, but from certain statements in his history it appears that he held the office of a "secretary" under Constantine the Great; and the fact that his history is dedicated to Valens shows that he was alive in the reign of the latter emperor. This work, published under the title of *Breviarium Historiæ Romanæ*, is a compend in ten books of the entire Roman history from the foundation of the city to the accession of Valens. This treatise has been compiled with considerable care from the best accessible authorities, and is written generally with impartiality, and in a clear and simple style. Besides chronicling events, Eutropius usually gives brief characteristics of the leading historical personages. Although his Latin style in some instances differs from that of the purest models, the work was for a long time a favorite elementary school-book. As a history its independent value is not great, and occasional mistakes have been discovered in it, both in regard to matters of fact and in chronology; but it is sometimes serviceable in supplying the lacunæ occurring in history from the total loss of some of the classics, and the imperfect state in which others have come down to us. There have been many editions of Eutropius. That by Havercamp was reputed the best till the appearance of the more complete and critical ones by Tzschucke, Leipsic, 1798, and Grosse, Halle, 1813. Several other editions have been published since that of Grosse, the best being that of Guil. Hartel, Berlin, 1872. Of the two Greek translations of Eutropius, that by Capito Lycius has long since perished; the more recent version of Pæanius, which is rather a periphrasis than a translation, will be found incorporated with the best editions of the Latin text.

EUTYCHES, the founder of the sect of the Eutychians, was a presbyter and archimandrite at Constantinople, and first came into notice in 431 A.D. at the council of Ephesus, where, as a zealous adherent of Cyril and the Alexandrine school, he vehemently opposed the doctrine of the Nestorians. They were accused of teaching that the divine nature was not incarnated in but only attendant on Jesus, being superadded to his human nature after the latter was completely formed. In opposition to this Eutyches went so far as to affirm that after the union of the two natures, the human and the divine, Christ had only one nature, that of the incarnate Word, and that therefore His human body was essentially different from other human bodies. In this he went beyond Cyril and the Alexandrine school generally, who, although they expressed the unity of the two natures in Christ so as almost to nullify their duality, yet took care verbally to guard themselves against the accusation of in any way circumscribing or modifying his real and true humanity. It would seem, however, that Eutyches differed from the Alexandrine school chiefly from inability to express his meaning with proper guardedness, for equally with them he denied that Christ's human nature was either transmuted or absorbed into his divine nature. The energy and imprudence of Eutyches in asserting his opinions led to his being accused of heresy by Eusebius, bishop of Dorylæum, at a council presided over by Flavian at Constantinople in 448. As his explanations were not considered satisfactory, the council deposed him from his priestly office and excommunicated him; but in 449, at a council convened by Dioscorus of Alexandria and overawed by the presence of a large number of Egyptian monks, not only was Eutyches reinstated in his office, but Eusebius and Flavian, his chief opponents, were deposed, and the Alexandrine doctrine of the "one nature" received the sanction of the church. Two years afterwards, however, by a council which met at Chalcedon. the synod of Ephesus was declared to have been a "robber synod," its proceedings were annulled, and, in opposition to the doctrines of Eutyches, it was declared that the two natures were united in Christ, but without any alteration, absorption, or confusion. Eutyches died in exile, but of his later life nothing is known. After his death his doctrines obtained the support of the empress Eudocia, and made considerable progress in Syria. In the 6th century they received a new impulse from a monk of the name of Jacob, who united the various divisions into which the Eutychians, or Monophysites, had separated into one church, which exists at the present time under the name of the Jacobite Church, and has numerous adherents in Armenia, Egypt, and Ethiopia.

EUYUK, or ÜYÜK, a Turkish village of Asia Minor, is situated about 75 miles W.S.W. of Amasia, and 28 miles south of the Kizil Irmak river, on a small hill which is a spur from higher hills to the north of it. It consists of only about twenty houses, but contains perhaps the most important ruins in Asia Minor. They are the remains of a large building, and consist of colossal blocks of granite containing a great variety of sculptures very little defaced. The upper portion of the walls seems to have been formed of clay, as there are no remains of overturned materials. In form the building resembles an Assyrian palace, and has been conjectured by some to have been erected by the builders of the palaces of Nineveh, adopting in this instance, as they are known to have done in others, Egyptian figures and emblems. But not merely from the sphinxes, but from the character of the human figures, Van Lennep considers that it was more probably a temple erected by Egyptians, who adopted an Assyrian form of building; and he conjectures that it dates back to the earliest Egyptian conquests in Asia Minor.

See Hamilton's *Asia Minor*, 1842; Barth's *Reise von Trapezunt nach Skutari*, 1860; and Van Lennep, *Asia Minor*, 1870.

EVAGORAS, king of Salamis, is said to have been descended from a family who claimed Teucer, brother of Ajax, as their progenitor, and who for a long period had been rulers of Salamis until expelled by a Phœnician exile. Evagoras, notwithstanding the expulsion of his ancestors, seems to have been born at Salamis, and lived there till the throne was again usurped by a Cyprian noble,—when, either from a prudent resolve to avoid the possibility of danger, or on account of information which he received of the usurper's designs against his life, he fled to Cilicia. Thence he returned secretly to Salamis in 410 B.C.; and, having with the aid of a small band of adherents overpowered the guards of the palace and put the tyrant to death, he mounted the throne. According to Isocrates, Evagoras was a just and wise ruler, whose aim was to promote alike the general well-being of his state and the welfare of his individual subjects, and this not merely by an increase of wealth and of the luxuries which it can provide, but by the cultivation of the Grecian arts of refinement and civilization, which had been almost obliterated in Salamis by a long period of barbarian rule. He endeavored in every way to promote friendly relations with the Athenians, and after the defeat of the Athenian general Conon at Ægospotami, he gave him refuge and a cordial reception. He also endeavored, at least for a time, to secure the friendship of Persia, and concluded a treaty with Artaxerxes II., whose aid he secured for the Athenians against Lacedæmon. Conjointly with the Persians and Athenians, he assisted in gaining the battle of Cnidus, 394 B.C., and for this service his statue was placed by the Athenians side by side with that of their general Conon in the Ceramicus. Not long after this his friendly relations with Persia seem to have been annulled, very probably because the Persian monarch was jealous of his enterprising and independent spirit, and of his increasing influence. Direct war between him and Persia did not, however, occur until after the peace negotiated by Antalcidas, 387; but he took advantage of the Persians being otherwise engaged to extend his rule over the greater part of Cyprus, and to stir up revolt among the Cilicians. As soon as the Persians were free to devote their whole attention to him, these acts were speedily revenged. He was totally defeated by a largely superior Persian force, and compelled to flee to Salamis, which the Persians closely invested, and in all probability would soon have succeeded in capturing, had not dissensions broken out between the two generals, of which Evagoras took advantage to conclude a peace with one of them. By the terms of this peace, Evagoras was allowed to remain nominal king of Salamis, but apparently under the authority of Persia, and at all events with his independence, if not altogether overthrown at least very much crippled. About ten years after this, 374 B.C., Evagoras was assassinated by a eunuch from motives of private revenge.

EVAGRIUS, surnamed Scholasticus and Ex-Præfectus, was born at Epiphania in Syria, 536 A.D. From his surname he is known to have been an advocate, and it is supposed that he practised at Antioch. He was the legal adviser of Gregory, patriarch of that city; and through this connection he was brought under the notice of the emperor Tiberius, who honored him with the rank of quæstorian. His influence and reputation were so considerable that on the occasion of his second marriage a public festival was celebrated in his honor, which, however, was interrupted by a terrible earthquake, said to have destroyed 60,000 persons. Evagrius's name has been preserved by his *Ecclesiastical History*, extending over the period from the third general council (that of Ephesus, 431) to the year 594. Though not wholly trustworthy, this work is tolerably impartial, and appears to have been compiled from original documents, but it is disfigured by the unquestioning credulity characteristic of the age. The best edition is that contained in Reading's *Greek Ecclesiastical Historians*, Cambridge, 1720. It is also translated in Bagster's work bearing the same title.

EVANDER. In the Roman tradition, as given by Livy, i. 5–7, the story of the Arcadian Evander is connected with the arrival of Hercules in Italy and his recovery of the cattle of Geryon from the robber Cacus. Evander, having left the Arcadian town of Pallantium, becomes the eponymus, or name-giver, of the Palatine, one of the seven hills of Rome. This is only one of many Greek legends adopted by the Romans for the purpose of connecting Italian places with others of like-sounding names in Greece. The time when this story was embodied into Latin tradition cannot be precisely ascertained; but we may safely assign it to the period when Greek influence began to make itself widely felt in the Italian peninsula. The story is told with many variations, inconsistencies, and contradictions. According to Pausanias (viii. 43, 2), Evander was the son of Hermes and a daughter of the river Ladon; others spoke of him as a son of Echemus and Timandra. The motives which led him to leave Arcadia are also variously stated. The Latin writers made him a son of Mercury and the prophetess Carmenta, whose name belongs strictly to Italian mythology. So again, while one version of the story represents him as being hospitably welcomed in Italy, another speaks of him as gaining a footing in it by force, and after slaying Herilus, king of Præneste. It would follow of necessity that the Italian legend would describe Evander as one who introduced Greek customs and rites into his new country, and would attribute to him such inventions as those which the Theban myth assigned to the Phœnician Cadmus. (See Dion. Hal. i. 33; Cornewall Lewis, *Credibility of Early Roman History*, ch. viii. § 4.)

EVANGELICAL ALLIANCE, an association of different Christian denominations formed in London in August, 1846, at a conference of more than 800 clergymen and laymen from all parts of the world, and embracing upwards of fifty sections of the Protestant church. Though the proposal for an alliance was first mooted in England, it ultimately obtained wide support in other countries, more especially in America, and organizations in connection with it now exist in the different capitals throughout the world. The object of the Alliance, according to a resolution of the first conference, is "to enable Christians to realize in themselves and to exhibit to others that a living and everlasting union binds all true believers together in the fellowship of the church." At the same conference the following was adopted as the basis of the Alliance:—"Evangelical views in regard to the divine inspiration, authority, and sufficiency of the Holy Scriptures; the right and duty of private judgment in the interpretation of the Holy Scriptures; the unity of the Godhead and the Trinity of persons therein; the utter depravity of human nature in consequence of the fall; the incarnation of the Son of God, His work of atonement for sinners of mankind, and His mediatorial intercession and reign; the justification of the sinner by faith alone; the work of the Holy Spirit in the conversion and sanctification of the sinner; the immortality of the soul, the resurrection of the body, the judgment of the world by our Lord Jesus Christ, with the eternal blessedness of the righteous and the eternal punishment of the wicked; the divine institution of the Christian ministry, and the obligation and perpetuity of the ordinances of Baptism and the Lord's Supper;"—it being understood, however, 1st, that such a summary "is not to be regarded in any formal or ecclesiastical sense as a creed or confession;" and 2d, that "the selection of certain tenets, with the omission of others, is not to be held as implying that the former constitute the whole body of important truth, or that the latter are unimportant." Annual conferences of branches of the Alliance are held in England, America, and several Continental countries; and it is provided that a general conference, including representatives of the whole Alliance, be held every seventh year, or oftener if it be deemed necessary. Such conferences have been held in London in 1851; Paris, 1855; Berlin, 1857; Geneva, 1861; Amsterdam, 1867; New York, 1873. They are occupied with the discussion chiefly of the "best methods of counteracting infidelity," promoting Christian union, organizing Christian agencies, and generally advancing the cause of Christianity,—every subject being avoided which might give rise to any serious divergence of opinion among the members. The various organizations of the Alliance lend their aid to any department of Christian effort requiring special help; and on several occasions their influence has been advantageously employed in cases of religious persecution.

See Reports of the Proceedings of the different general conferences, which have been published under the following titles: *The Evangelical Alliance*, London, 1847; *The Religious Condition of Christendom*, London, 1852; *The Religious Condition of Christendom*, London, 1859; *The Geneva Conference of the Evangelical Alliance*, London, 1862; *Evangelische Alliantie*, Rotterdam, 1867, and *Proceedings of the Amsterdam Conference*, London, 1868; and *Evangelical Alliance Conference 1873*, New York, 1874.

EVANGELICAL ASSOCIATION, an American religious denomination originated about the beginning of the present century by Jacob Albrecht, a German Lutheran of Pennsylvania. About 1790 he began an itinerant mission among his fellow-countrymen, chiefly in Pennsylvania; and his labors meeting with considerable success, he was, at an assembly composed of representatives of the different stations, elected in 1800 presiding elder or chief pastor, and shortly afterwards rules of government were adopted somewhat similar to those of the Methodist Episcopal Church. In 1816 the first annual conference was held, and in 1843 there was instituted a general conference, composed of delegates chosen by the annual conferences and constituting the highest legislative and judicial authority in the church. The members of the general conference hold office for four years. In 1873 the association comprised 15 annual conferences, consisting of over 600 itinerant and 400 local preachers, possessed 4 training colleges, and numbered 83,195 members.

EVANGELICAL UNION, a religious denomination which originated in the deposition of the Rev. James Morison, minister of a United Secession congregation in Kilmarnock, Scotland, for certain views regarding faith, the work of the Spirit in salvation, and the extent of the atonement, which were regarded by the supreme court of his church as anti-Calvinistic and heretical. His deposition took place in 1841; and his father, who was minister at Bathgate, and other two ministers being deposed not long afterwards for similar opinions, the four met at Kilmarnock in May, 1843, and, on the basis of certain doctrinal principles, formed themselves into an association under the name of the Evangelical Union, "for the purpose of countenancing, counselling, and otherwise aiding one another, and also for the purpose of training up spiritual and devoted young men to carry forward the work and 'pleasure of the Lord.'" The doctrinal views of the new denomination gradually assumed a more decidedly anti-Calvinistic form, and they began also to find many sympathizers among the Congregationalists of Scotland. Nine students were expelled from the Congregational Academy for holding "Morisonian" doctrines, and in 1845 eight churches were disjoined from the Congregational Union of Scotland and formed a connection with the Evangelical Union. In 1858 the Evangelical Union issued a new doctrinal statement superseding that of 1843. The Union exercises no jurisdiction over the individual churches connected with it, and in this respect it adheres to the Independent or Congregational form of church government; but while the affairs of those of its congregations which originally belonged to the Independent denomination are managed by meetings of all the communicants, those congregations which originally were Presbyterian vest their government in a body of elders. The churches connected with the Evangelical Union number nearly 90, only a few of which are in England. Its ministers are eligible for Congregational churches in England, and for some time negotiations have been in progress for an amalgamation of the denomination with the Congregational Union of Scotland. See *Evangelical Union Annual*, and *History of the Evangelical Union*, by F. Ferguson, D.D. (Glasgow, 1876).

EVANS, Sir De Lacy (1787–1870), a distinguished British soldier, son of John Evans of Milltown, Limerick, Ireland, was born in 1787. He was educated at Woolwich Academy, and entered the army in 1807 as ensign in the 22d regiment of foot. His regiment was immediately afterwards gazetted for India, and during his stay of three years in that country he served with distinction in various actions. In 1812, as lieutenant of the 3d Dragoons, he joined the Peninsular army of Wellington; and in the Portuguese and Spanish campaigns of 1812, 1813, and 1814 he acquired a high reputation both for military skill and for personal bravery. He was rapidly promoted by merit, and in 1814 received the rank of lieutenant-colonel. The same year, in command of the 5th West India Regiment, he was sent to take part in the war against the United States, where he specially distinguished himself at the capture of Washington, and shared in the attack on Baltimore and the operations before New Orleans. He returned to England in the spring of 1815 in time to accompany the expedition of Wellington to Flanders, and was assistant quartermaster-general at Quatre Bras and Waterloo. As a member of the staff of the duke of Wellington he accompanied the English army to Paris, and remained there during the occupation of the city by the allies. In 1831 Evans entered the House of Commons as Liberal member for Rye; but in the election of 1832 he was an unsuccessful candidate both for that borough and for Westminster. For the latter constituency he was, however, returned in 1833, and, with the exception of the parliament of 1841-46, continued to represent it till 1865, when he retired from political life. His parliamentary duties did not, however, interfere with his career as a soldier. In 1835 he was sent in command of 10,000 men (the "Spanish Legion") to aid the queen of Spain against Don Carlos. He remained two years, and gained several brilliant though bloody victories; and on his return in 1839 he was, in recognition of his achievements, created Knight Commander of the Bath. In 1846 he attained the rank of major-general; and in 1854, on the breaking out of the Russian war, he was appointed to the command of the second division of the army of the East. At the battle of the Alma his quick comprehension of the features of the combat largely contributed at various critical periods to the victory. On the 26th October, by the skilful manner in which he handled his troops, he brilliantly defeated, at a nominal loss, a large division of Russian forces which had attacked his position on Mount Inkerman. Illness and fatigue compelled him a few days after this to leave the command of his division in the hands of General Pennefather; but he rose from his sick-bed on the day of the battle of Inkerman, November 5, and declining to take the supreme command of his division from General Pennefather, he generously aided him in his long-protracted struggle by his countenance and advice. On the return of Evans to England in the following February invalided, he received for his services in the Crimea the thanks of the House of Commons, and the same year he was made Knight Grand Cross of the Order of the Bath, and the university of Oxford conferred on him the degree of D.C.L. In 1856 he received the Grand Cross of the Legion of Honor, and in 1861 he was gazetted general. He died 9th January, 1870.

EVANS, Oliver (1755–1819), an American mechanician, was born at Newport, Delaware, in 1755. He was at an early age apprenticed to a wheelwright, and at the age of twenty-two he invented a machine for making card-teeth in lieu of the old method of making them by hand. In 1780 he became partner with his brothers, who were practical millers; and two years later he completed an invention which totally changed the structure of flour mills. About the same time he discovered the application of steam to land carriages, and in 1786 he endeavored to obtain patents for the two inventions from the State of Pennsylvania. A patent for the former was granted in 1787, but the latter request was considered too absurd to merit consideration. It was granted, however, in 1797 by the State of Maryland. About this time he sent drawings and specifications of his plans to England, but they were received there with the same incredulity as in America. Meantime he made use of the engine he had invented—the first constructed on the high-pressure principle—for his flour mill; and in 1803 he constructed a steam dredging machine, which also propelled itself on land. Evans used all his means in experiments on his invention; and though he did not live to see its full application, he was confident that its results would be as great as they have actually turned out to be. In 1819 a fire broke out in his factory at Pittsburg, and its consequences were so disastrous to his immediate hopes that he did not long survive its occurrence, dying April 21, 1819.

EVANSON, Edward (1731–1805), a theological writer whose views gave rise to much controversy, was born at Warrington, in Lancashire, April 21, 1731. At the age of seven he was placed under the care of an uncle, vicar of Mitcham, in Surrey. At fourteen he entered Emmanuel College, Cambridge, where he graduated B.A. in 1749. In 1753 he took his degree of M.A.; and, after being ordained, he officiated for several years as curate at Mitcham. In 1768 he became vicar of South Mimms near Barnet; and in November, 1769, he was presented to the rectory of Tewkesbury, with which he also held the vicarage of Longdon. In the course of his studies and inquiries after truth he discovered what he thought important variance between the teaching of the Church of England and that of the Bible, and he did not conceal his convictions. He allowed himself in reading the service to alter or omit phrases which seemed to him untrue, and in reading the Scriptures to point out errors in the translation, a practice which was offensive to many of his congregation. A crisis was brought on by his sermon on the resurrection preached at Easter, 1771; and in November, 1773, a prosecution was instituted against him in the Consistory Court of Gloucester. He was charged with "depraving the public worship of God contained in the liturgy of the Church of England, asserting the same to be superstitious and unchristian, preaching, writing, and conversing against the creeds and the divinity of our Saviour, and assuming to himself the power of making arbitrary alterations in his performance of the public worship." A protest was at once signed and published by a large number of the parishioners against the prosecution. The case was carried by appeal to the Court of Arches and the Court of Delegates, and was ultimately quashed on merely technical grounds in 1777. Meanwhile Evanson had made his views generally known by several publications. In 1772 appeared anonymously his *Doctrines of a Trinity and the Incarnation of God, examined upon the Principles of Reason and Common Sense.* This was followed in 1777 by *A Letter to Dr. Hurd, Bishop of Worcester, wherein the Importance of the Prophecies of the New Testament and the Nature of the Grand Apostasy predicted in them are particularly and impartially considered.* The author had before this time retired to Longdon, leaving his curate in charge at Tewkesbury. In 1775 he was appointed domestic chaplain to the solicitor-general, and at the close of 1777 he resigned both his livings, and retired to Mitcham. In 1786 he married. He soon after wrote some papers on the Sabbath, which brought him into controversy with Dr. Priestley, who published the whole discussion (1792). In the same year appeared Evanson's work entitled *The Dissonance of the four generally received Evangelists*, to which replies were published by Dr. Priestley and D. Simpson, M.A. (1793). Evanson rejected most of the books of the New Testament as forgeries, and of the four gospels he accepted only that of St. Luke. In 1802 he published *Reflections upon the State of Religion in Christendom*, in which he attempted to explain and illustrate the mysterious foreshadowings of the Apocalypse. This he considered the most important of his writings. Shortly before his death he completed his *Second Thoughts on the Trinity*, in reply to a work of the bishop of Gloucester. The story of the life, investigations, and conflicts of this heretical churchman of a hundred years ago is full of interest, especially for its anticipations of some of the momentous discussions of the present day. He died at Colford, in Gloucestershire, September 25, 1805. A narrative of the circumstances which led to the prosecution of Evanson was published by N. Havard, the town-clerk of Tewkesbury.

EVANSVILLE, a city of America, capital of Vanderburg county, Indiana, is situated on a high bank of the Ohio river, 200 miles below Louisville, Kentucky—measuring by the windings of the river, which double the direct distance. On account of the peculiar bend of the river at this point, Evansville is built somewhat in the shape of a crescent, and is sometimes called the "Crescent City." It has railway communication in various directions; and the Wabash and Erie Canal, completed in 1853, extends from it to Toledo, Ohio, a distance of 400 miles. Evansville is a busy commercial and manufacturing town, and is rapidly increasing. It is the principal shipping port for the grain and pork of south-western Indiana; and among its other articles of export are lime, cotton, dried fruit, and tobacco. It has flour mills, breweries, iron foundries, tanneries, machine shops, and woollen and cotton factories. Coal and iron ore are found in the vicinity. The principal buildings are the court-house, the city hall, the high school, the marine hospital, and a new building in which are included the post-office, the United States courts, and the custom-house. The population, which in 1860 was 11,484, had increased in 1870 to 21,830.

EVAPORATION is that process by which liquids and solids assume the gaseous state at their free surfaces. The rate at which evaporation takes place depends upon the temperature of the liquid or solid, the extent of the exposed surface, and the facility with which the gaseous particles can escape from the neighborhood of the surface either by diffusion through the air or by the motion of the air itself. Hence a strong wind will generally accelerate the process of drying. The passage from the gaseous into the liquid condition, or *condensation*, and into the solid condition, or *sublimation*, are processes the converse of evaporation. The evaporation of a liquid is a phenomenon which we observe daily, and that of a solid sometimes presents itself to our notice, as when snow vanishes by evaporation during a long frost though the temperature never rises to the freezing point. Camphor and iodine also readily evaporate at ordinary temperatures without liquefying, and sublime on the surface of the vessels in which they are placed.

A gas is a substance a finite portion of which will distribute itself through any space, however great, to which it has free access. A substance which can exist in the liquid or solid state at ordinary temperature and under ordinary atmospheric pressure is usually, when in the gaseous condition, called a vapor; but, though it is easy to give arbitrary definitions, no satisfactory distinction between gases and vapors has yet been made. In fact, the word "vapor" is rapidly giving place to "gas" in most instances. The greatest amount of any substance which can exist in the gaseous condition in the unit of volume depends upon the temperature, but is almost independent of the presence of any other vapor or gas, provided that such gas or vapor possess no chemical affinity for the substance in question. When a portion of space contains as much of any vapor as can exist in it at the temperature, it is said to be *saturated* with that vapor. Any reduction of temperature will then be accompanied by condensation of part of the vapor, and the space will remain saturated at the new temperature; while if any increase of temperature occur, the space will cease to be saturated with the vapor it contains, and further evaporation will take place if any of the corresponding liquid be present, but if not the space will remain unsaturated, and the vapor it contains is then said to be *super-heated*. If the fall of temperature be caused by the introduction of a solid body sufficiently cold, condensation will first take place in the layer of air next the body, forming *dew* upon its surface if the temperature be above that at which the vapor solidifies, but *hoar-frost* if the temperature be below that point, in which case we have an example of *sublimation*. If the reduction of temperature be occasioned by the introduction of a quantity of cold air or other gas, or by the rapid expansion of the vapor itself, together with any other vapors or gases which may occupy the same space, the condensed liquid assumes the state of cloud, fog, or mist. The temperature at which a portion of space is saturated with the aqueous vapor which it actually contains was called by Dalton the *dew-point*. Some vapors, like steam at 100° C., if allowed to expand without receiving heat, and in expanding to do the full amount of work corresponding to the greatest pressure they can exert, suffer partial condensation, because the increase in the space occupied does not compensate for the reduction of temperature; but there are other vapors which become super-heated by expansion, because the increase in volume more than compensates for the reduction of temperature.

When the temperature of a liquid is such that the pressure of its vapor is less than that to which the liquid is exposed, evaporation will go on at its free surface only, but if the temperature is raised so that the pressure of the vapor is greater than that exerted upon the liquid, bubbles of vapor can exist within the liquid itself, and if once formed will rise through the liquid and escape at the surface. This phenomenon is called *ebullition* or *boiling;* and the temperature at which the pressure of the vapor of a substance is equal to the standard atmospheric pressure is called its *boiling-point*. The standard atmospheric pressure generally adopted is that exerted by a column of mercury 760 millimetres in height at 0° C. at the sea level in latitude 45°. This is equivalent to about 29·905 inches of mercury at 0° C. at the sea-level in the latitude of London. The pressure of a megadyne per square centimetre has been proposed as the standard atmosphere, but this has not yet been generally adopted.

When a quanity of water is heated from the lower surface, the water near the bottom is at a higher temperature than the superincumbent layers, and the bubbles of steam formed there on rising are surrounded by water at a temperature below the boiling-point, and being consequently unable to sustain the pressure to which they are exposed, they collapse with a slight sound. These sounds repeated in rapid succession constitute the "singing" of the kettle, and are exchanged for a very much softer sound when the whole of the water reaches the boiling-point, and steam bubbles escape from the surface. Though bubbles of pure steam once produced can exist under atmospheric pressure if the temperature be above the boiling-point, yet such bubbles will not necessarily be produced in pure water as soon as it reaches that temperature. If water which has been carefully freed from air by long boiling be heated in a clean glass vessel, its temperature may be raised considerably above the boiling-point; but as soon as the continuity of the water is broken by the formation of a bubble of steam, ebullition ensues with explosive violence, and the temperature falls nearly to the boiling-point. Drops of water suspended in a mixture of linseed oil and oil of cloves of the same specific gravity have been heated by Dufour to 180° C., and generally fatty oils poured on the surface of water tend to prevent ebullition. It has been stated that the boiling of *pure* water has not yet been observed. Certain solutions, especially strong solutions of caustic alkalies, are very liable to an explosive evolution of steam at intervals, and the best way of preventing it is the introduction, when possible, of a small piece of a metal which can decompose water.

Though the temperature at which water boils depends on the impurities which it contains, and the nature of the vessel in which it is placed, yet the temperature of the steam above the water depends only on the pressure. This has been long acknowledged when the quantity of impurity dissolved in the water is small, and in order to determine the boiling-points upon thermometers they are immersed in the steam above boiling water without allowing their bulbs to touch the water. When the quantity of salt dissolved is very great, the temperature of the boiling solution is generally very much above the boiling-point of water. Thus, according to Faraday, saturated solutions of common salt, nitre, and potassic carbonate boil at 109°, 115·6°, and 140° C. respectively. The temperature of ebullition of a saline solution is sometimes employed to determine the percentage of salt present. Notwithstanding the high temperature of the solution, it seems that the temperature of the steam when first liberated from the solution is the same as that produced by water boiling at the same pressure. This conclusion is supported by Dufour, though Magnus and some others were of a different opinion. If a thermometer with a clean unprotected bulb be immersed in the steam above a concentrated saline solution boiling at ordinary pressure, its temperature will quickly rise to 100° C., then become almost stationary, and afterwards slowly rise to a temperature somewhat below that of the liquid, and depending on its nearness to the solution and the facilities which are offered for the escape of heat from the bulb. On removing the thermometer and allowing it to cool, there will generally be found a quantity of salt sticking to the bulb which has been splashed upon it from the solution. If the bulb of a thermometer be covered with cotton which has been sprinkled with some salt, and be then immersed in steam, whether above a saline solution or above boiling water, its temperature will quickly rise considerably above the boiling-point, and several thermometers whose bulbs have been covered with different salts will indicate different temperatures if suspended side by side in the same vessel of steam, leading us to suspect that the high temperature recorded by the thermometer above the saline solution may be due in part at least to salt which has been splashed upon the bulb. If the bulb be protected from splashes by a metal screen placed below it, and from condensed water trickling down the stem by a guard placed above it, the temperature will at once rise to 100° C.; but the further rise of temperature will be so slow that it may be accounted for by the radiation from the liquid and from the metal screen, which of course becomes heated in the same way as a naked thermometer placed in its position. If a test tube containing mercury be immersed in the solution, and the thermometer bulb placed in it till it reaches the same temperature, on raising it into the steam the temperature will be seen to fall considerably.

If a small quantity of a liquid be placed in a metal vessel whose temperature has been raised very much above the boiling-point of the liquid, vapor will be produced so rapidly from the under surface of the liquid that it will be supported on a cushion of its own vapor, and thus prevented from coming into contact with the metal, the separation being so complete that if the liquid be an electrolyte a current from an ordinary battery cannot be made to pass from the liquid to the metal. This condition of the liquid is called the spheroidal state, and is often referred to as Leidenfrost's phenomenon. It may frequently be noticed that the drop is in a state of rapid rotation. If by any means an indentation is made in the surface of the drop, vibrations will be set up in it, causing the horizontal section to pass into the form of a curvilinear polygon, in the same manner as the edge of a bell changes its form when struck. The surface of the drop then presents a "beaded" or corrugated appearance, formed by the superposition of the retinal images of the drop in the two extreme conditions which it assumes, and therefore always presenting an *even* number of corrugations corresponding to the vibrating segments. Surface tension of course supplies the forces necessary to produce the vibrations. When a ventral segment projects beyond the mean surface of the drop so as to form a "bead," more surface is exposed by it to the heating action of the metal than when it is in its mean position, and when it lies within the mean, or spheroidal, surface so as to form a "flute," less surface is exposed by it; but as the generation of steam cannot be instantaneous, more steam will escape from the segment while it is receding towards the centre than while it is advancing, and thus the pressure of the escaping steam upon each ventral segment will vary with the phase of vibration in such a manner as to supply the energy necessary to the continuance of the motion. If the drop be examined by ordinary daylight a fluted outline can be distinctly seen within the beaded outline, but if it be instantaneously illuminated by electric sparks, the separate vibration forms will be seen presenting half as many beads and flutes as are presented when the images are superposed through the employment of a continuous light. The lowest temperature at which the spheroidal condition can be produced varies with the nature of the heated surface, the liquid, and the temperature of the liquid when poured into the vessel. It is in virtue of this condition that Faraday found it possible to freeze mercury in a red-hot vessel. When the metal is allowed to cool sufficiently, the liquid comes into contact with it, and is wholly or partially converted into vapor with explosive violence. In highly rarefied air water will assume the spheroidal condition at very low temperatures, in consequence of evaporation being accelerated by the diminution of pressure.

Previous to the introduction of the molecular theory of gases many theories were proposed to explain the diffusion of aqueous vapor through the air. Halley supposed that vapor consisted of small hollow spherules or *vesicles* filled with an *aura* considerably lighter than air, which caused them to ascend like balloons, and Atwood followed his hypothesis. Even after the similarity of vapors to air and other so-called permanent gases had been fully recognized, the *vesicular* theory was still held in a modified form to explain the suspension of cloud and fog; but in the case of very small drops the resistance of the air is sufficient to prevent the drops acquiring more than an extremely small velocity in consequence of their weight. Hooke supposed that air contains aqueous vapor in a state of chemical solution; but this theory, like the preceding, fails to explain evaporation in vacuo. De Saussure believed that water was first converted into vapor by the action of heat, and then absorbed by the air on account of a chemical affinity; while Halley, Leroy, and Franklin thought that the attraction of the air was instrumental in the first formation of vapor. The advocates of a still older theory maintained that aqueous vapor was a combination of water particles with those of fire, which caused them to ascend, and that contrary winds blowing the particles of water together loosened the fire particles from them, thus allowing them to descend as rain.

Desaguliers seems to have been the first to identify the nature of steam with that of aqueous vapor at ordinary temperatures, and to recognize the fact that steam is a transparent gas, while the cloud produced by a jet of steam is really condensed water. In a letter to the president of the Royal Society (*Phil. Trans.*, 1729, p. 6), Desaguliers maintained that the cause of vapor rising in the air is a force of repulsion between its particles, which separates them so far from each other as to render the vapor specifically lighter than air. The resistance offered by water to compression he accounts for by a similar repulsion. From some experiments with a steam-engine he concluded that water in being converted into steam under ordinary atmospheric pressure expands to about 14,000 times its original volume instead of about 1650 times, as it actually does. Shortly after the above-mentioned letter was written, Desaguliers, in "An Essay on the Cause of the Rise of Vapors and Exhalations in the Air" (*Natural Philosophy*, pt. ii.), attributed the repulsion between the particles of vapor to an electrical action, supposing that the particles of water were first electrified from the air and then repelled by the air and by one another.

In 1783 De Saussure published his *Essais sur l'Hygrométrie*, which give an account of many experiments executed on a great scale, and in some cases leading him to correct conclusions. By placing a known weight of dry potassic carbonate in a large glass balloon filled with air and saturated with aqueous vapor, and finding the increase in the weight of the carbonate produced by absorption, he determined the amount of vapor originally present. By filling the balloon with dry air, and suspending in it a piece of wet linen, he determined the amount of the water which evaporated from the loss of weight experienced by the linen. These experiments were repeated with the balloon filled with hydrogen and carbonic anhydride, and with mixtures of these gases, and both methods led to the same result, indicating that the amount of vapor was the same, if the temperature remained constant, whatever gas were present. The inferences he derived from his experiments at different temperatures were not, however, justifiable; nor is there any ground for his division of vapor into four classes, viz., pure elastic vapor, dissolved elastic vapor, vesicular vapor, and concrete vapor, the last of which really consists of liquid drops.

Deluc (*Phil. Trans.*, 1792) enunciated the theory that the quantity of vapor which can exist in any space depends *only on the temperature*, and is independent of the presence of any other vapor or gas with which it has no tendency to combine chemically, being always the same as if nothing but the vapor occupied the space; and this he verified by placing his hygrometer with a little water under the receiver of an air-pump, and showing that the indications of the hygrometer were independent of the pressure of the air. Deluc was the first to propose that the hygrometric state of the air should be measured by the ratio of the amount of vapor existing in it to that required to saturate it at the temperature it possesses. A more convenient measure has been proposed by Balfour Stewart, viz., the quantity of vapor associated with the unit of mass of dry air.

But it is to Dalton that we are chiefly indebted for a clear statement of the laws of evaporation. In his *Meteorological Essays* (1793, p. 134) he states that "evaporation and the condensation of vapor are not the effects of chemical affinities, but aqueous vapor always exists as a fluid *sui* *generis* diffused amongst the rest of the aërial fluids." Thus water at 80° Fahr. is on the point of boiling under a pressure of 1·03 inches of mercury, and from this he concludes that in the presence of dry air water at 80° Fahr. will evaporate "till the density of its vapor, considered abstractedly, becomes $\frac{1}{29}$th of what it is under a pressure of 30 inches, and its temperature 212°." This statement, though inaccurate inasmuch as it takes no account of the expansion of a given mass of steam at constant pressure when its temperature is raised from 80° Fahr. to 212° Fahr., yet shows that Dalton had discovered the true law of evaporation, and thoroughly understood its applications. If we substitute pressure for density, the statement becomes correct. Again, on page 201 of the *Essays* he states his conviction, as the result of experiments and observations,

> "That *the vapor of water* (*and probably of most other liquids*) *exists at all temperatures in the atmosphere, and is capable of bearing any known degree of cold without a total condensation, and that the vapor so existing is one and the same thing as steam or vapor of 212° or upwards.* The idea, therefore, that vapor cannot exist in the open atmosphere at a lower temperature than 212°, unless chemically combined therewith, I consider as erroneous; it has taken its rise from the supposition that *air* pressing upon *vapor* condenses the vapor equally with *vapor* pressing upon *vapor,*—a supposition we have no right to assume, and which, I apprehend, will plainly appear to be contradictory to reason and unwarranted by facts; for when a particle of vapor exists between two particles of air, let their equal and opposite pressures upon it be what they may, they cannot bring it nearer to another particle of vapor, without which no condensation can take place, all other circumstances being the same; and it has never been proved that the vapor in a receiver from which all the air has been exhausted is precipitated upon the admission of perfectly dry air. Hence, then, we conclude, till the contrary can be proved, that *the condensation of vapor exposed to the common air does not in any way depend upon the pressure of the air.*"

(The Italics are Dalton's.) In these remarks Dalton manifests a clear appreciation of the true state of the case. In his experiments he aimed directly at the root of the matter, and the results at which he arrived are perfectly conclusive within the errors of his experiments. First he measured the pressure of a quantity of dry air kept at constant volume for every degree on Fahrenheit's scale between the freezing and boiling points; then he found the pressure of pure steam in contact with water for every degree through the same range, and lastly the rate of increase of pressure of a quantity of air kept at constant volume but in contact with water when the temperature varied. The results showed that at each particular temperature the pressure of the air saturated with vapor was exactly equal to that corresponding to the dry air together with that exerted by vapor alone when in contact with water at the same temperature; from which he inferred that there is either no chemical action between the air and vapor, or such action in no way affects the question at issue with gases other than air and vapors other than aqueous. This conclusion is frequently expressed by saying that gases and vapors behave to one another as vacua. Most of these experiments were published in a paper in the *Manchester Memoirs*, vol. v.

Dalton was the first to give a table of the maximum pressure of steam for temperatures from 80° to 212° Fahr.

The researches of Desormes, Gay Lussac, and Daniell all tend to corroborate Dalton's theory and the accuracy of his experiments, the results of which may be summed up in two statements, sometimes cited as Dalton's laws, viz:—

I. In a space which contains a liquid and its vapor only, the liquid will continue to evaporate until the pressure of its vapor attains a determinate amount dependent only on the temperature.

II. In a space containing dry air or other gas or gases a liquid will continue to evaporate until the pressure exerted *by its vapor alone* is the same as if no air or other gas were present.

The more recent researches of Regnault and Andrews have shown that the second law is not quite true. It was, however, a great step in advance, and is sufficiently accurate for all the purposes of chemical analysis and hygrometry. Two or more vapors will act towards one another as vacua when, and only when, their liquids have no affinity for one another. When this is not the case, the pressure exerted by the vapor above the surface of the mixed liquids is frequently much less than that which can be exerted by the vapor of the more volatile liquid alone. Thus sulphuric acid will absorb aqueous vapor, and alcohol will absorb ether vapor, reducing the pressure to a small fraction of that exerted by the ether vapor alone. Bisulphide of carbon and paraffin oil also diminish the pressure of ether vapor. Since a mixture of liquids may boil when the pressure of the vapor produced exceeds that to which the liquid is exposed, it follows that a mixture of liquids which have no tendency to dissolve one another will boil at a temperature below the boiling-point of either of them; but when the liquids have an affinity for each other the boiling-point of the mixture will be above that of the more volatile constituent.

The method employed by Gay Lussac for the measurement of the pressure of aqueous vapor at low temperatures has not since been improved upon. He employed a barometer tube whose length was considerably greater than the height of the barometer, and having bent the upper portion (above the mercury) over so as to slope downwards at an angle of about 60° with the horizon, he immersed the closed end in a cold mixture at the temperature for which the pressure was to be measured, and injected a little water into the barometer tube. The vapor produced condensed in the cold part of the tube, and this process of distillation continued until the whole of the water had evaporated from the surface of the mercury, leaving it free to rise and fall in the tube. The pressure of the vapor was afterwards always that due to the temperature of the coldest part of the tube, for if at any time it exceeded this pressure, condensation would commence and continue until the pressure was reduced to this amount. A barometer tube dipping into the same trough of mercury, and containing no water, was placed by the side of the experimental tube, and the difference in the level of the mercury in the tubes was read by means of a microscope sliding on a graduated pillar, this difference obviously indicating the pressure of the vapor.

The rate at which evaporation takes place has been the subject of much inquiry. In 1772 Dr. Dobson of Liverpool (*Phil. Trans.*, lxvii.) placed a cylindrical vessel, 12 inches in diameter, by the side of a rain-gauge, and, allowing for the rain which fell into it, determined the total evaporation during each month for four years. Dalton and Hoyle imitated more closely the conditions presented by the soil, and filled a vessel three feet in depth with gravel and sand, covering it with earth and sinking it in the ground; a pipe was placed near the top and one near the bottom in order to collect any water which might be free to run off, while the amount of rain received was measured by rain-gauge placed close to the vessel. At the commencement of the series of observations the contents of the vessel were saturated with water, and the difference between the amount of rain received and of water that escaped by the pipes indicated the amount of evaporation.

From observations of the rate of evaporation of water contained in a shallow tin dish Dalton concluded that at different temperatures in calm air the rate of evaporation is proportional to the maximum pressure of steam at that temperature, diminished by the pressure of the vapor already existing in the air, which pressure is determined from an observation of the dew-point, and that when the air is in motion the rate of evaporation increases with the velocity of the wind. It really depends not only on the temperature, but on the rate at which the vapor can escape from the neighborhood of the liquid, and evaporation therefore proceeds more quickly when the pressure of the air is diminished. Some considerations on the subject will be found in the article DIFFUSION.

Many of Dalton's experiments were subsequently repeated in a modified form by Daniell, who examined the pressure of steam at various temperatures, and in the presence of other gases, as well as the rate of evaporation. The chief monument of Daniell's work on this subject is his dew-point instrument. Hutton was the first to suggest the determination of the hygrometric state of the air from the cold produced by evaporation; and Sir John Leslie employed the same method, in connection with the differential thermometer. For the theory of Mason's dry and wet bulb thermometers, or, as it is sometimes called, August's psychrometer, see article DIFFUSION.

In 1823 the determination of the maximum pressure of aqueous vapor at different temperatures was referred to a commission of the Academy of Paris, and the work was undertaken by Dulong and Arago. They measured the pressure of steam at temperatures ranging from 100° C. to 224° C., by observing the compression of a quantity of air imprisoned by mercury in a tube. About the same time a committee of the Franklin Institute of Pennsylvania measured the temperature of steam in contact with water, at pressures varying from one to ten atmospheres; but the results of the two series of experiments did not agree very well. It was partly on this account that Regnault determined to investigate the subject more thoroughly, and it is to him we are indebted for a table of the pressure of aqueous vapor over a range of temperature varying from −32° C. to 230° C. Some of his results, together with some obtained by Magnus, will be found in the accompanying table. The pressures are measured in millimetres of mercury at 0° C. 60 metres above the level of the sea in the latitude of Paris. An account of Regnault's researches on this subject will be found in the *Mémoires de l'Institut*, tome xxi., the *Nouvelles Annales de Chimie*, xi. 334, and xiii. 396, and in the first volume of the publications of the Cavendish Society. The researches of Magnus, who arrived independently at nearly the same results as Regnault, were published in *Poggendorff's Annalen*, lxi. 225.

Regnault also determined the density of aqueous vapor in air and in vacuo for temperatures between 0° C. and 25° C., and concluded that when the pressure is not very great nor the air nearly saturated (for when it is nearly saturated there is probably deposition of moisture upon the glass vessels), the density may be calculated from the known density of steam at the boiling-point and under ordinary atmospheric pressure by supposing it to obey "the gaseous laws." According to Regnault the mass of a litre of dry air at 0° C., and under a pressure of 760 millimetres of mercury, is 1·293187 grammes, and the density of steam, compared with air at the same pressure and temperature as unity, is ·6235. Hence, by help of the table of pressures, the amount of aqueous vapor in any given volume can be determined when we know the dew-point and the temperature of the air. If P denote the pressure of vapor at the dew-point in millimetres of mercury, the mass of vapor in a litre of air at t° C. will be

$$1{\cdot}293187 \times \frac{P}{760} \times \frac{273}{273+t} \text{ grammes.}$$

A curve which represents the relation between the pressure and volume of the unit mass of steam in contact with water as the temperature changes is called the *steam line*, and the corresponding curve for aqueous vapor in contact with ice is called the *hoar-frost line*. Since water can be cooled below the freezing-point without solidifying, it is possible to obtain data for drawing the steam line corresponding to a range of temperature below 0° C. This Regnault did, and his results showed that the steam line so continued does not coincide with the hoar-frost line, but that the two intersect very obliquely just above the freezing-point. Regnault supposed that this must be due to errors of measurement, and drew his steam line so as to coincide with the hoar-frost line; but it has since been shown from theoretical considerations, by James Thomson, that such a difference must exist, and that the point of intersection of the two curves corresponds to a particular relation between the pressure, volume, and temperature for which ice, water, and steam can all exist together in equilibrium, no other gas or vapor being present in the enclosure. On examining Regnault's results, the intersection of the curves was found to be distinctly indicated by them. At this point the steam line, ice line, and hoar-frost line intersect, and it has therefore been called the triple point. The corresponding temperature is a little above 0·007° C.

The number of units of heat absorbed by the unit of mass of a substance, in passing from the solid or liquid into the gaseous condition, without change of temperature is called the *latent heat of vaporization*. According to Andrews, the latent heat of steam at 100° C. is 535·9, or a gramme of water in being converted into steam at 100° C. would absorb sufficient heat to raise 535·9 grammes from 0° to 1° C.

Soon after Dr. Black annunciated his theory of latent heat James Watt examined the latent heat of steam produced at different temperatures, and concluded that, when added to the amount of heat required to raise the unit of mass of water from 0° C. to the temperature at which the steam is formed, the result, often called the *total heat of steam*, is the same for all temperatures. This statement is known as Watt's law, but is far from true, for Regnault has shown experimentally that when steam is produced at a temperature of t° C. its total heat is represented by $606{\cdot}5 + {\cdot}305t$ within the limits of error of his experiments. Putting t equal to 100, this formula gives for the total heat of steam at 100° C. the value 637, and its latent heat is therefore about 536, since about 101 units of heat are required to raise the unit mass of water from 0° C. to 100° C. At 0° C. the latent heat of steam is 606·5. The latent heat of steam is greater than that of any other known vapor. According to Favre and Silbermann, the latent heat of the vapors of alcohol and ether are 208·31 and 91·11 respectively; and according to Andrews, they are 202.4 and 90.45 respectively.

In consequence of the great amount of heat absorbed in evaporating, volatile liquids are frequently employed for the purpose of producing cold. The cryophorus of Wollaston consists of a glass tube with a bulb at each end, one of which is partially filled with water. The air is removed by boiling the water and sealing the tube when full of steam. On turning all the water into one bulb, and placing the other in a mixture of pounded ice and salt, the pressure of vapor will be diminished by condensation taking place in the cold bulb, and this allows such rapid evaporation to take place in the other bulb that the water remaining in it becomes readily frozen. Gay Lussac showed that water placed in a vacuum at 8° C., or in perfectly dry air at 2° C., may be frozen by evaporation. The action of Carré's freezing-machine depends upon the heat absorbed by the rapid evaporation of ammonia, which has been liquefied by pressure.

Solid carbonic anhydride dissolved in ether will produce by evaporation *in vacuo* a temperature of about − 110° C., and Natterer, by means of a mixture of liquid nitrous oxide and bisulphide of carbon evaporating in vacuo, obtained a temperature which he estimated at − 140° C.

When a vapor passes into the liquid or solid state a quantity of heat is produced equal to that absorbed in evaporating at the same temperature. Thus, if a gramme of steam be made to pass into 5·36 grammes of water at 0°, it will raise the temperature of the water almost to 100° C., and if steam at 100° C. be blown into a saturated solution of common salt, the temperature will rise to 109° C. before the steam will pass freely through it.

In 1822 Cagniard de la Tour inclosed a quantity of alcohol in a strong tube, so as to occupy about two-fifths of its volume. A pellet of mercury was employed to separate the alcohol from some air, the compression of which served to measure the pressure in the tube. On heating the alcohol to about 225° C. (according to De la Tour) it expanded to about twice its volume, and then suddenly disappeared, the pressure being (according to the same authority) about 129 atmospheres. When the quantity of alcohol filled a much greater portion of the tube, the tube burst. The experiment was repeated with ether, naphtha, and water, with similar results; but in the case of water it was necessary to add a little sodic carbonate to prevent the water dissolving the glass. The experiments have since been repeated by Faraday, and still more recently by Andrews. It was first noticed by Wolf (*Ann. de Chimie*, xlix. 230), afterwards by Drion (*Ann. de Chimie*, lvi. 221), who examined Wolf's results, experimenting with ether, and with ethylic chloride, and subsequently by Andrews, that the curvature of the surface of the liquid decreases as the temperature is raised, indicating a diminution in the surface tension, while the surface itself becomes less strongly marked, till it entirely loses its curvature, and then vanishes altogether, only a flickering hazy appearance being visible in different parts of the tube. The temperature at which the liquid and gaseous states merge into one another has been called by Andrews the *critical point*. Mendeleef calls it the *absolute boiling-point*. The temperatures and pressures corresponding to the critical points of some substances are given in the following table:—

	Temperature.	Pressure in atmospheres.
Carbonic anhydride	30·92° C.	75
Ether	187·5	37·5
Alcohol	258·7	119·0
Carbonic bisulphide	262·5	66·5
Water	411·7	?

According to Drion, the critical points of ether, ethylic chloride, and sulphurous anhydride are 190°·5 C., 184° C., and 157° C. respectively. Wolf experimented upon the diminution of the surface tension of ether, water, and other liquids in capillary tubes, and finding it diminish uniformly as the temperature increased between 0° C. and 100° C., he calculated the temperatures at which the surface tension would entirely vanish, and obtained 217° C. for ether and 537° C. for water.

Van der Waals (*Over de Continuiteit van den Gas- en Vloeistofloestand*, vii.), by taking into account the mutual attraction of the molecules and the volume occupied by the molecules themselves, has arrived at an equation which represents in a somewhat rough manner the relation between the volume, temperature, and pressure of a substance. When the pressure and temperature are given, there are generally three roots representing the volume in the liquid, gaseous, and unstable states respectively. At the critical point these three roots become equal.

From the values of the volume and pressure of water and steam at 0°, 100°, and 200° C., as deduced by Rankine from the observations of Regnault, Clerk Maxwell has calculated that the critical temperature for water should be about 434° C., the critical pressure about 378 atmospheres, and the critical volume about 2·52 cubit centimetres per gramme.

Dr. Andrews has constructed an apparatus for the liquefaction of carbonic anhydride, in which the gas is contained in a thermometer tube whose lower portion is much wider than the upper part, and immersed in mercury contained in a test tube, which is placed in a copper cylinder filled with water, to which pressure is applied by inserting a steel screw. The lower end of the glass tube is open, and the upper part projects beyond the copper cylinder. If the carbonic anhydride be heated beyond the critical point, pressure being applied so as to keep some of the substance liquid until the critical point is reached, and if the gas be then allowed to cool under this pressure, it will pass continuously into the liquid state without any change in the nature of the contents of the tube being apparent. On relieving the pressure the liquid will boil.

By the simultaneous application of cold and pressure Faraday succeeded in reducing to the liquid state all known gases, except hydrogen, oxygen, nitrogen, nitric oxide, carbonic oxide, and marsh gas, and in solidifying many of them. The cooling was effected by the evaporation in vacuo of solid carbonic anhydride dissolved in ether, which produced a temperature of about − 110° C.; and by this means carbonic anhydride, chlorine, nitrous oxide, ammonia, cyanogen, and some other gases were liquefied by cold alone at atmospheric pressure. Faraday was of opinion that − 110° C. is above the critical temperature of air, oxygen, hydrogen, nitrogen, carbonic oxide, and marsh gas. Andrews subsequently reduced air to $\frac{1}{675}$ of its volume at ordinary pressure and temperature by means of pressure and the cold produced by the same freezing mixture as was employed by Faraday. Hydrogen was reduced to $\frac{1}{500}$ of its volume, oxygen to $\frac{1}{554}$, and nitric oxide to $\frac{1}{680}$, but no liquefaction ensued.

Towards the close of 1877 Cailletet, at Chatillon-sur-Seine, compressed air and other so-called permanent gases in an apparatus very similar to that of Andrews, but provided with a means of suddenly relieving the pressure. The compressed gases were cooled to − 29° C., and the cold produced by the sudden expansion when the pressure was relieved was so intense that in each case a liquid spray was produced. About the same time Pictet, at Geneva, succeeded, not only in liquefying all the gases which had previously resisted liquefaction, but also in solidifying hydrogen, his method depending on the cold produced by expansion, as in Cailletet's experiment, but the compressed gases being cooled by him to a much lower temperature before expansion than was employed by Cailletet.

Some of the laws of evaporation admit of easy explanation, in accordance with the dynamical theory of the constitution of bodies. When a particle of liquid in the course of its wanderings reaches the bounding surface with more than a certain normal velocity, it is able to pass through the surface and get quite clear of the liquid, when it becomes a particle of gas or vapor. The number of particles passing through a square centimetre of the surface from the liquid will depend upon the velocity of the liquid particles, and therefore on the temperature of the liquid, but it will be entirely independent of the condition of affairs outside the liquid. Hence, the quantity of liquid which evaporates in a second will not depend upon the pressures of any gases or vapors above the liquid, but only on the temperature. Whenever a particle of vapor moves towards the surface of the liquid and reaches it, it enters the liquid and is *condensed*. The quantity of vapor so condensed in a second will depend on the velocity of translation of the particles of vapor and the number of such particles in each cubic centimetre of the space above the liquid, but will not be sensibly affected by the presence of particles of other gases or vapors in the same space. As the density of the vapor increases, the number of particles which enter the liquid per second will increase proportionally, and at length will become equal to the number which leave it. When this is the case evaporation appears to cease; but it is not a cessation of evaporation which actually takes place, but an increase in the rate of condensation which produces a condition of dynamical equilibrium. If there be a quantity of another gas above the surface of the liquid, its presence will hinder the diffusion of the vapor just formed, thus causing the amount of vapor near the liquid to approach more nearly to the state of saturation than would otherwise be the case, and thus the rate of condensation will be increased, and the apparent rate of evaporation diminished. Nevertheless, we must conclude that the amount of vapor ultimately contained in each cubic centimetre of the space above the liquid, when no further evaporation takes place, will be the same as if no other gas or vapor were present, if we do not consider the space actually occupied by the particles themselves, for the number of particles prevented from entering the liquid by reflection from the foreign gas or vapor, will be exactly equal to the number which after leaving the liquid are reflected, and caused to re-enter the liquid by the same means.

For further information on this subject the reader is referred, among other articles, to DIFFUSION, HEAT, and METEOROLOGY. (W. G.)

EVE, the English transcription, through the Latin *Eva* and Greek Εὔα, of the Hebrew name חַוָּה Havva, which, according to Gen. iii. 20, was given by Adam to his wife because she was "mother of all living." Taken literally, the word means *life*, and in this sense it occurs in Phœnician, though not in Hebrew, which uses as a common noun the slightly different form חַיָּה. So the Septuagint correctly renders the word by Ζωή. The rendering *lifegiver* (Symmachus, Ζωογόνος) is philologically less satisfactory, though still supported by Riehm.[1]

---

[1] Other ancient etymologies, which have no scientific value, but are in part connected with curious speculations, may be found in the *Onomastica* (Ed. Lagarde, 1870) and in Fabricius, *Codex Pseudep. V. T.*, p. 103. The recent conjecture of Kleinert, who connects the name with Arabic *el hawâni, the longest ribs*, is philogically inadmissible.

In the Old Testament Eve is mentioned only in the so-called Jehovistic narrative of Gen. ii.–iv. In this narrative, which it is unnecessary to repeat, the original creation of woman is so set forth as to teach the ethical value and dignity of the relation of marriage, which according to God's original ordinance is not founded on sensual instincts, but corresponds to a necessity of that higher part of man's nature which raises him above the brute creation (Gen. ii. 18–20). The relation of the wife to her husband is one of dependence (comp. 1 Tim. ii. 13, but especially 1 Cor. xi. 8, 9, which rightly interprets the significance of the creation of Eve from Adam's rib), but not of subjection. The woman is not the servant of her husband, but a "help meet for him"—more literally a help corresponding to him—without which he would be himself incomplete. And so marriage constitutes the closest human relationship, and establishes between husband and wife a union, or rather a unity, stronger than the ties of blood (Gen. ii. 24). On the other hand, the dominion of the husband over the wife characteristic of antique society is represented as a fruit of the fall (Gen. iii. 16), and connected with the predominance of sensual passion (desire) over the ethical attachment of the sexes. These ideas reappear more or less clearly in various parts of the Old Testament,—in the description of true love in Canticles, and in what is said of marriage in the Proverbs, especially in the doctrine, Prov. ii. 17, that marriage is a "divine covenant." But there is no direct reference to the narrative of Genesis in the other canonical books of the Old Testament, though some interpreters seek an allusion to the creation of Adam and Eve in the obscure passage Mal. ii. 15. In the apocryphal book of Tobit (viii. 6, 7) the pure relation of true marriage is illustrated by reference to Gen. ii.;[1] but it is only in the New Testament that the original ideal of married life is authoritatively set forth by our Lord as the rule of a higher morality than that of Mosaism (Matt. xix.; Mark x.). The abrogation of the one-sided law of divorce, and the restoration of marriage to the ideal instituted before the fall, involve the abolition in Christian society of the antique subjection of woman (comp. Hosea ii. 16). The other parts of the history of Eve have less importance for biblical theology and ethics, and receive little more than casual notice in the New Testament (2 Cor. xi. 3; 1 Tim. ii. 14, 15).

To this notice of the biblical materials on the subject may be added a brief indication of the legendary additions to the narrative of Genesis, and some account of the way in which that narrative has been treated by theologians and scholars in different ages.

Legends.—The earliest source for the legendary history of Eve which remains to us is the book of Jubilees or Leptogenesis, a Palestinian work, composed before the destruction of the temple by Titus (see APOCALYPTIC LITERATURE). In this book, which was largely used by Christian writers, we find a chronology of the lives of Adam and Eve and the names of their daughters,—Avan and Azura.[2] The Targum of Jonathan informs us that Eve was created from the thirteenth rib of Adam's right side, thus taking the view, still soberly maintained by Delitzsch, that Adam had a rib more than his descendants. The Jewish Midrash and the Talmud contain many other stories, always absurd and often disgusting, of which a sufficient account may be found in Bartolocci's *Bibliotheca Rabbinica*, and Eisenmenger's *Entdecktes Judenthum*. The curious reader may also consult Breithaupt's Latin translation of Jarchi *On the Pentateuch* (Gotha, 1710), and Wagenseil's *Sota* (pp. 637, 751). Some of the Jewish legends show clear marks of foreign influence. Thus the notion that the first man was a double being, afterwards separated into the two persons of Adam and Eve (*Berachot*, *f.* 61; *Erubin*, *f.* 18), may be traced back to Philo (*De mundi opif.*, § 53; comp. *Quæst in Gen.*, lib. i. § 25), who borrows the idea, and almost the words, of the myth related by Aristophanes in the Platonic *Symposium*, which, in extravagant form, explains the passion of love by the legend that male and female originally formed one body. This myth, which is treated with much respect by later Platonists, may have come from the East, but it is not Semitic. There is an analogous Eranian legend in the Bundehesh,[3] and an Indian legend, which, according to Spiegel, has presumably an Eranian source.[4]

Legendary developments of the history of Adam and Eve were not confined to the Jews, but were equally popular in the Christian church and among the heretical sects. The apocryphal literature of the subject is noticed in the article ADAM; but a reference may here be added to the history of Adam and Eve published by Ceriani, *Monumenta sacra et profana*, tom. v., Milan, 1868. An idea of the contents of this literature may be derived from Rœnsch's *Buch der Jubiläen*. See also Fabricius, *Codex Pseudep. V. T.*, p. 95, *seq.*

History of Interpretation.—The following remarks are supplementary to what has been already said in the article ADAM.

Minds trained under the influence of the Jewish Haggada, in which the whole biblical history is freely intermixed with legendary and parabolic matter, would not naturally formulate the question how far the story of Gen. ii.–iv. is to be regarded as literal history. But that question necessarily arose when Jewish learning came into contact with Greek thought. Josephus, in the prologue to his *Archæology*, reserves the problem of the true meaning of the Mosaic narrative, but does not regard everything as strictly literal. Philo, the great representative of Alexandrian allegory, expressly argues that in the nature of things the trees of life and knowledge cannot be taken otherwise than symbolically. His interpretation of the creation of Eve is, as has been already observed, plainly suggested by a Platonic myth. The longing for reunion which love implants in the divided halves of the original dual man is the source of sensual pleasure (symbolized by the serpent), which in turn is the beginning of all transgression. Eve represents the sensuous or perceptive part of man's nature, Adam the reason. The serpent therefore does not venture to attack Adam directly. It is sense which yields to pleasure, and in turn enslaves the reason and destroys its immortal virtue. This exposition, in which the elements of the Bible narrative become mere symbols of the abstract notions of Greek philosophy, and are adapted to Greek conceptions of the origin of evil in the material and sensuous part of man, was adopted into Christian theology by Clement and Origen, notwithstanding its obvious inconsistency with the Pauline anthropology, and the difficulty which its supporters felt in reconciling it with the Christian doctrine of the excellence of the married state (Clemens Alex., *Stromata*, p. 174). These difficulties had more weight with the Western church, which, less devoted to speculative abstractions and more deeply influenced by the Pauline anthropology, refused, especially since Augustine, to reduce Paradise and the fall to the region of pure *intelligibilia*; though a spiritual sense was admitted along with the literal (Aug., *Civ. Dei*, xiii. 21).[5]

The history of Adam and Eve became the basis of anthropological discussions which acquired more than speculative importance from their connection with the doctrine of original sin and the meaning of the sacrament of baptism. One or two points in Augustinian teaching may be here mentioned as having to do particularly with Eve. The question whether the soul of Eve was derived from Adam or directly infused by the Creator is raised as an element in the great problem of traducianism and creationism (*De Gen. ad lit.*, lib. x.). And it is from Augustine that Milton derives the idea that Adam sinned, not from desire for the forbidden fruit, but because love forbade him to dissociate his fate from Eve's (*ibid.*, lib. xi. *sub fin.*). Mediæval discussion moved mainly in the lines laid down by Augustine. A sufficient sample of the way in which the subject was treated by the schoolmen may be found in the *Summa* of Thomas, pars i., qu. xcii., *De productione mulieris.*

The Reformers, always hostile to allegory, and in this matter especially influenced by the Augustinian anthropology, adhered strictly to the literal interpretation of the history of the Protoplasts, which has continued to be generally identified with Protestant orthodoxy. The disintegration of the confessional doctrine of sin in last century was naturally associated with new theories of the meaning of the biblical narrative; but neither renewed forms of the allegorical interpretation, in which everything is reduced to abstract ideas about reason and sensuality, nor the attempts of Eichhorn and others to extract a kernel of simple history by allowing largely for the influence of poetical form in so early a narrative, have found lasting acceptance. On the other hand, the strict historical interpretation is beset with difficulties which modern interpreters have felt with increasing force, and which there is a growing disposition to solve by adopting in one or other form what is called the "*mythical*" theory of the narrative. But interpretations pass under this now popular title which have no real claim to be so designated. What is common to the "mythical" interpretations is to find the real value of the narrative, not in the form of the story, but in the thoughts which it embodies. But the story cannot be called a myth in the strict sense of the word, unless we are prepared to place it on one line with the myths of heathenism, produced by the unconscious play of plastic fancy, giving shape to the impressions of natural phenomena on primitive observers. Such a theory does no justice to a narrative which embodies profound truths peculiar to the religion of revelation. Other forms of the so-called mythical interpretation are little more than abstract allegory in a new guise, ignoring the fact that the biblical story does not teach general truths which repeat themselves in every individual, but gives a view of the purpose of man's creation, and of the origin of sin, in connection with the divine plan of redemption. Among his other services in refutation of the unhistorical rationalism of last century, Kant has the merit of having forcibly recalled attention to the fact that the narrative of Genesis, even if we do not take it literally, must be regarded as presenting a view of the beginnings of the history of the human race (*Muthmasslicher Anfang der Menschengeschichte*, 1786). Those who recognize this fact ought not to call themselves or be called by others adherents of the mythical theory, although they also recognize that in the nature of things the divine truths brought out in the history of the creation and fall could not have been expressed either in the form of literal history or in the shape of abstract metaphysical doctrine; or even although they may hold,—as is done by many who accept the narrative as a part of supernatural revelation,—that the specific biblical truths which the narrative conveys are presented through the vehicle of a story which, at least in some of its parts, may possibly be shaped by the influence of legends common to the Hebrews with their heathen neighbors. It must, however, be remembered that speculation as to the affinities of Genesis with other and especially Babylonian legends has of late far outrun the bounds of scientific method; and this caution has a special application to the supposed Babylonian history of the fall. See Von Gutschmidt's *Neue Beiträge*, p. 146 (Leipsic, 1876). (W. R. S.)

---

[1] Another reference to the creation of woman appears in the Latin text of Ecclesiasticus xvii. 5, but is lacking in the Greek.

[2] These names underwent many transformations in the course of time. The various forms are carefully catalogued by Rœnsch, *Buch der Jubiläen*, p. 373 (Leipsic, 1874). Jewish, Mahometan, and Christian notions about the children of the Protoplasts are collected with his usual learning by Selden, *De Jure Naturali, etc.*, lib. v. cap. 8.

[4] Muir's *Sanscrit Texts*, vol. i. p. 25; *cf.* Spiegel, *op. cit.*, vol. i. p. 458.

[5] Thus in mediæval theology Eve is a type of the church, and her formation from the rib has a mystic reason, inasmuch as blood and water (the sacraments of the church) flowed from the side of Christ on the cross (Thomas, *Summa*, par. i. qu. xcii.).

EVELYN, JOHN (1620–1706), the diarist and author of *Sylva*, was born at his father's seat at Wotton, in Surrey, on the 31st October, 1620. He was the younger son of a country gentleman of large estate, and much respected throughout the counties of Surrey and Sussex, of which he was high sheriff, one high sheriff at that time serving for both counties. Notwithstanding the wealth and position of his family, John Evelyn was educated at the free school of Lewes, where his maternal grandfather resided. While still at school, he was admitted into the Inner Temple; and in the following month, at the age of sixteen, he entered Balliol College, Oxford, as a fellow-commoner. In July, 1641, having lost his father during the previous year, he retired from England, which was then on the eve of civil war. Before proceeding with his travels, he expressed his sympathy with the cause of the queen of Bohemia, which was dear to all Protestant Englishmen, by serving in her army for a few days, "according to the compliment." The ten following years he spent abroad, only making brief visits to England.

It is with this period of travel that his famous *Diary*, which he had commenced in imitation of his father at eleven years of age, begins to be full and interesting. This diary is for many reasons of value to the student of history and manners. It comprises the long period, so rich in great events, between the outbreak of the civil war and the accession of Anne. Written with no thought of publication, it embodies the frankest expression of its author's opinions, and affords much curious and interesting information which the historian would have probably passed over, but which throws a strong light upon the customs and feelings of the age. And Evelyn's statements are always worthy of at least a respectful hearing. In an age of fiercest political and ecclesiastical conflict, himself subject to strong temptations to partisanship, he maintained throughout life the same calm temperance of judgment; and, amid general profligacy, the purity and integrity of his character remained unstained. The competence of his fortune and the moderation of his ambition rendered him politically independent. His attachment to monarchy did not blind him to the vices of kings. Though an earnest Protestant and a firm Episcopalian, he did not allow himself to be carried away into the extravagant bigotry so common among his contemporaries; he deprecated the persecution of the Protestant dissenters, and though he wrote against the Jesuits, he refused to join in the mad hatred with which all who professed the Roman Catholic faith were popularly regarded.

In 1652 Evelyn returned home with his wife, the amiable and talented daughter of Sir Richard Browne, and settled at Sayes Court, the house afterwards famous as the residence of Peter the Great. Though well known to be a royalist, he was not molested, except on one occasion, when he was arrested by a party of fanatic soldiers for observing Christmas Day, but, nothing else being proved against him, was at once released. On the death of Cromwell, he published an *Apology for the Royal Party*, and tried in vain to persuade Colonel Morley to declare for Charles II. From the Restoration till his death in 1706 he enjoyed unbroken court favor. In the reign of James II., during the absence of the earl of Clarendon in Ireland, he acted as one of the commissioners of the Privy Seal, and honorably distinguished himself by refusing, at the risk of offending the king, to sign an illegal license of popish books. But, with this exception, he never accepted an office of political importance. His life, however, was filled with useful work. He was commissioner for improving the streets and buildings of London, for "charitable uses" (*i.e.*, for examining into the affairs of charitable institutions), and for taking care of the wounded who were brought home during the Dutch war, commissioner of the mint, commissioner of trade and plantations, etc. His love of science led to his being chosen secretary of the Royal Society, and he twice declined the presidency. It was through his influence that the Arundelian marbles and the library and MSS. of the earl of Arundel were presented to the university of Oxford, a service which the university recognized by conferring upon him the degree of D.C.L. His writings were exceedingly numerous. The best known were his *Diary* and *Sylva*, an elaborate treatise on arboriculture. Among the others may be mentioned *Navigation and Commerce, their Original and Progress*, intended as an introduction to a history of the Dutch war, which he both commenced and laid aside at the command of Charles II.; *A Parallel of Ancient and Modern Architecture; Public Employment preferred to Solitude*; and *The History of the Four Great Impostors*. The first collection of Evelyn's miscellaneous writings, several of which had been published anonymously, appeared in 1825, printed in facsimile, and edited by W. Upcott.

EVEMERUS, or EUHEMERUS, a Greek mythographer, who flourished in the latter half of the 4th century B.C. The place of his birth is unknown, but most probably it was either Messina in Sicily or Agrigentum. He is noted chiefly for his *Sacred History* (Ἱερὰ ἀναγραφή), founded professedly on archaic inscriptions which he had collected during his travels in various parts of Greece, and more especially on those observed on the temple of Jupiter Triphylianus, in the island of Panchæa. In this work he introduced a new method of interpreting the popular myths, asserting that the gods who formed the chief objects of popular worship had been originally heroes and conquerors, who had thus earned a claim to the veneration of their subjects. Till the end of the last century there were many who accepted this system of Evemerus, and the early Christians especially appealed to it as a confirmation of their belief that the ancient mythology was merely an aggregate of fables of human invention. Evemerus was a firm upholder of the Cyrenaic philosophy, and by many ancient writers he was regarded as an atheist. His work was translated by Ennius into Latin, but the work itself is lost, and of the translation only a few fragments, and these very short, have come down to us.

EVERDINGEN. Three painters of this name are recorded in the history of Dutch art,—all of them related; but one only deserves to be remembered.

Allart von Everdingen (1621–? 1675) the son of a Government clerk at Alkmaar, was born, it is said, in 1621, and educated, if we believe an old tradition, under Roeland Savery at Utrecht. He wandered in 1645 to Haarlem, where he studied under Peter de Molyn, and finally settled about 1657 at Amsterdam, where he remained till his death. It would be difficult to find a greater contrast than that which is presented by the works of Savery and Everdingen. Savery inherited the gaudy style of the Breughels, which he carried into the 17th century; whilst Everdingen realized the large and effective system of colored and powerfully shaded landscape which marks the precursors of Rembrandt. It is not easy on this account to believe that Savery was Everdingen's master, while it is quite within the range of probability that he acquired the elements of landscape painting from De Molyn. Pieter de Molyn, by birth a Londoner, lived from 1624 till 1661 in Haarlem. He went periodically on visits to Norway, and his works, though scarce, exhibit a broad and sweeping mode of execution differing but slightly from that transferred at the opening of the 17th century from Jan Van Goyen to Solomon Ruysdael. His etchings have nearly the breadth and effect of those of Everdingen. It is still an open question when De Molyn wielded influence on his clever disciple. Alkmaar, a busy trading place near the Texel, had little of the picturesque for an artist except polders and downs or waves and sky. Accordingly we find Allart at first a painter of coast scenery. But on one of his expeditions he is said to have been cast ashore in Norway, and during the repairs of his ship he visited the inland valleys, and thus gave a new course to his art. In early pieces he cleverly represents the sea in motion under varied, but mostly clouded, aspects of sky. Their general intonation is strong and brown, and effects are rendered in a powerful key, but the execution is much more uniform than that of Jacob Ruysdael. A dark scud lowering on a rolling sea near the walls of Flushing characterizes Everdingen's Mouth of the Schelde in the Hermitage at St. Petersburg. Storm is the marked feature of sea-pieces in the Stædel or Robartes collections; and a strand with wreckers at the foot of a cliff in the Munich Pinakothek may be a reminiscence of personal adventure in Norway. But the Norwegian coast was studied in calms as well as in gales; and a fine canvas belonging to Professor Piloty at Munich shows fishermen on a still and sunny day taking herrings to a smoking hut at the foot of a Norwegian crag. The earliest of Everdingen's sea pieces belongs to Mr. Von Friesen at Dresden, and bears the date of 1640. After 1645 we meet with nothing but representations of inland scenery, and particularly of Norwegian valleys, remarkable alike for wildness and a decisive depth of tone. The master's favorite theme is a fall in a glen, with mournful fringes of pines interspersed with birch, and log huts at the base of rocks and craggy slopes. The water tumbles over the foreground, so as to entitle the painter to the name of "inventor of cascades." It gives Everdingen his character as a precursor of Jacob Ruysdael in a certain form of landscape composition; but though very skilful in arrangement, and clever in effects, Everdingen remains much more simple in execution; he is much less subtle in feeling or varied in touch than his great and incomparable countryman. Five of Everdingen's cascades are in the museum of Copenhagen alone: of these, one is dated 1647, another 1649. In the Hermitage at Petersburg is a fine example of 1647; another in the Pinakothek at Munich was finished in 1656. English public galleries ignore Everdingen; but one of his best-known masterpieces is the Norwegian glen belonging to Lord Listowel. Few Continental museums lack pictures by this master. Their value in the market is about a third to a half of those of Ruysdael; but excepting the later and more neglected pieces, they are all clever and generally attractive. At Amsterdam, we may think, Everdingen chiefly produced etchings and drawings, of which there are much larger and more numerous specimens in England than elsewhere. Being a collector as well as an engraver and painter, he brought together a large number of works of all kinds and masters; and the sale of these by his heirs at Amsterdam on the 11th of March, 1676, gives an approximate clue to the date of the painter's death.

EVEREST, Sir George (1790–1866), C.B., a distinguished surveyor and geographer, was the son of Tristram Everest of Gwerndale, Brecknockshire, and was born there July 4, 1790. From school at Marlow he proceeded to the military academy at Woolwich, where he attracted the special notice of the mathematical master, Dr. Hutton, and passed so well in his examinations that he was declared fit for a commission before attaining the necessary age. Having gone to India in 1806 as a cadet in the Bengal Artillery, he was selected by Sir Stamford Raffles to take part in the reconnaissance of Java (1814–1816); and after being employed in various engineering works throughout India, he was appointed in 1818 assistant to Colonel Lambton, the founder of the great trigonometrical survey of that country. In 1823, on Colonel Lambton's death, he succeeded to the post of superintendent of the survey; in 1830 he was appointed by the court of directors of the East India Company surveyor-general of India; and from that date till his retirement from the service in 1843 he continued to discharge the laborious duties of both offices. During the rest of his life he resided in England, where he became fellow of the Royal Society and an active member of several other scientific associations. In 1861 he received the honor of knighthood, and he was chosen vice-president of the Royal Geographical Society in 1862. He died at Greenwich, December 1, 1866. The geodetical labors of Sir George Everest rank among the finest achievements of their kind; and more especially his measurement of the meridional arc of India, 11½° in length, is accounted as unrivalled in the annals of the science. In great part the Indian survey is what he made it. The name of Everest has been given in his honor to the highest ascertained peak of the Himalayas, and thus of the world.

His works are purely professional:—A paper in vol. i. of the *Memoirs of the Royal Astronomical Society*, pointing out a mistake in La Caille's measurement of an arc of the meridian which he had discovered during sick-leave at the Cape of Good Hope; *An account of the measurement of the arc of the meridian between the parallels of 18° 3′ and 24° 7′, being a continuation of the Grand Meridional Arc of India, as detailed by Lieut. Col. Lambton in the volumes of the Asiatic Society of Calcutta*, London, 1830; *An account of the measurement of two sections of the Meridional Arc of India bounded by the parallels of 18° 3′ 15″, 24° 7′ 11″, and 20° 30′ 48″*, London, 1847.

EVERETT, Alexander Hill (1792–1847), an American author and diplomatist, born at Boston, March 19, 1792, was the son of Rev. Oliver Everett, for some time a Congregational minister in Boston, and afterwards judge of probate for Norfolk County. He graduated at Harvard College, Cambridge, in 1806, taking the highest honors of his year, though the youngest member of his class. He spent one year as a teacher in Philip's Academy, Exeter, and then began the study of law in the office of John Quincy Adams, afterwards president of the United States. In 1809 Adams was appointed minister to Russia, and Everett accompanied him as his private secretary, remaining attached to the American legation in Russia until 1811. His assiduity in the diplomatic career resulted in his promotion successively to the position of secretary of legation and afterwards of chargé d'affaires at the Hague. He was subsequently minister to Spain, under the presidency of John Quincy Adams. At that time Spain recognized none of the Governments established by her revolted colonies, and Everett became the medium of all communications between the Spanish Government and the several nations of Spanish origin which had been established, by successful revolutions, on the other side of the ocean. He died, May 29, 1847, at Hong Kong, whither he had been sent as commissioner of the United States, before the present system of diplomatic intercourse with China was inaugurated.

Everett was not, however, so distinctly a diplomat as a man of letters. His long residence in Europe, and his intimate acquaintance with the French, German, Italian, and Spanish languages, resulted in wide and accurate acquaintance with the literature of the Continental states. He studied their political system at the same time, and in industrious and constant authorship published the results of his observations on social systems and literature. His coöperation was relied upon by the founders of the *North American Review*, the earliest American quarterly, and he was editor of that journal from the year 1829 to October, 1835. In 1822 he published in London and in Boston *A General Survey of Europe*, which discusses the Continental system and the balance of power as they were adjusted after the fall of Napoleon. It attracted general attention, and was translated into German, French, and Spanish. In 1825 he published in London and Boston *America*, a somewhat similar description of the nations of North and South America. This book also was translated into the principal European languages. In 1822 he published *New Ideas of Population*, suggested by Malthus's works, and replying to that author by a wider exposition than Malthus gave to the possibility of general and easy emigration. Some of his literary papers from the *North American Review* and the *Democratic Review*, and a volume of poems, have been published in Boston. No American writer of his time was better known on the continent of Europe.

EVERETT, EDWARD (1794–1865), brother of the preceding, was born in Dorchester, near Boston, on the 11th November, 1794. His father died in his childhood, and his mother removed to Boston with her family after her husband's death. When he was little more than thirteen he entered Harvard College; and as the full undergraduate course is four years, he became "bachelor of arts" at seventeen. He then took the first college honors of his class. While at college he was the chief editor of *The Lyceum*, the earliest in the series of college journals published at the American Cambridge. His verses and his prose essays then show some of the facility and grace which appear in his later writings, and much of the humor which in later times he was always trying to repress. His earlier predilections were for the study of law, but the advice of Joseph Stevens Buckminster, a distinguished preacher in Boston, led him to prepare for the pulpit, and in this calling he at once distinguished himself. He was called to the ministry of one of the largest Boston churches before he was twenty years old. His sermons and his theological writings attracted wide attention in that community. But his tastes were then, as always, those of a scholar; and in 1814, after a service of little more than a year in the pulpit, he resigned his charge to accept a professorship of Greek literature in Harvard College. After nearly five years spent in Europe in preparation, he entered with alacrity on his duties, and, for five years more, gave a vigorous impulse, not simply to the study of Greek, but to all the work of the college. About the same time he assumed the charge of the *North American Review*, which now became a quarterly; and he was indefatigable in contributing on a great variety of subjects, with a spirit like Sydney Smith's in the earlier days of the *Edinburgh Review*. He vigorously defended American institutions against the sneers of English travellers, and had reason to congratulate himself on the success of a series of articles written to bring about a better mutual understanding between Englishmen and Americans. The success of his lectures in Cambridge, and the enthusiasm aroused by the rebellion in Greece, led him to deliver a series of popular lectures on Greek antiquities in Boston. They were the first lectures on purely literary or historical subjects ever delivered in America, and were the first steps toward a system of popular entertainment and education which now has very wide sweep in the United States. He was eagerly engaged in the measures taken in the United States for the relief of Greece in her struggle.

In 1824 he was chosen a member of Congress, and held a seat for ten years, supporting generally the administration of Adams, and in opposition to that of Jackson, which succeeded it. As a member of the house of representatives he appears to have devoted himself mainly to the discharge of that part of the public business which devolved upon him. He took the floor less frequently than might perhaps have been expected from a person accustomed to public speaking, and able to command the ear of the house. It will be found, however, on looking back to the transactions of the ten years' sessions during which he was a member, that he bore a part in almost every important debate. He was on the committee of foreign affairs during the whole time of his service in Congress. Of all the most important select committees, such as those on the Indian relations of the State of Georgia, the Apportionment Bill, and the Bank of the United States, Everett was a member, and drew the report either of the majority or the minority. The report on the congress of Panama, the leading measure of the first session of the Nineteenth Congress, was drawn by Everett, although the youngest member of the committee, and just entered Congress. He led the opposition to the Indian policy of General Jackson (the removal of the Indians, without their consent, from lands guaranteed to them by treaty). In the winter of 1835 he was nominated as governor of Massachusetts, and was chosen in the autumn of the same year. He brought to the duties of the office the untiring diligence which is the characteristic of his public life. We can only allude to a few of the measures which received his efficient support,—*e.g.*, the establishment of the board of education, the first of such boards in the United States, the scientific surveys of the State, the first of such public surveys, the criminal law commission, and the preservation of a sound currency under the panic of 1837.

Everett filled the office of governor for four years. The political parties in Massachusetts were at this time very nearly balanced, and divisions of opinion on local questions (the militia and temperance laws) caused his defeat at the election in November, 1839. Judge Morton, the opposing candidate, succeeded by a single vote, out of more than a hundred thousand. Everett availed himself of this opportunity, the following spring, to make a visit with his family to Europe. In 1841, while residing in Florence, he was named United States minister to England, and arrived in London to enter upon the duties of his mission at the close of that year. Great questions were at that time open between the two countries,—the north-eastern boundary, the affair of M'Leod, the seizure of American vessels on the coast of Africa, in the course of a few months the affair of the "Creole," to which were soon added Oregon and Texas. His position was more difficult by the frequent changes that took place in the department at home, which in the course of two years was occupied successively by Messrs. Webster, Legaré, Upshur, Calhoun, and Buchanan. From all these gentlemen Everett received marks of approbation and confidence.

By the institution of the special mission of Lord Ashburton, the direct negotiations between the two Governments were, about the time of Everett's arrival in London, transferred to Washington. It appears, however, from documents that have from time to time been communicated to Congress, that various topics connected with all the subjects in dispute were incidentally treated in the correspondence of the American minister at London both with his own and the British Government. Many elaborate notes to Lord Aberdeen and despatches to the American secretary of state have in this way come before the public, forming, however, it is believed, but a small part of the documents of both classes prepared by Everett during his mission. It appears, indeed, that, from the concurrence of a variety of causes, the amount of business transacted at the American legation from 1841 to 1845 was more than double that of any former period of equal duration.

Immediately after the accession of Polk to the presidency Everett was recalled. Shortly before his return the presidency of Harvard College was vacated by the resignation of Hon. Josiah Quincy, and Everett was strongly urged by the friends and governors of the institution to accept this office, which he did in the month of January, 1846. He filled this place of equal distinction and usefulness for about three years. It was a position congenial with his tastes, in harmony with the early associations of his life, and one which seemed to promise large opportunity of applying for the benefit of the rising generation the fruit of his maturer studies and varied experience in life. His health unfortunately soon began to suffer, and before long became seriously impaired under the burdens and cares of the office, and he was compelled at the close of the year 1848 to tender his resignation. Relieved of this charge, he supposed that at last he was to enjoy literary or scholarly leisure, and was already preparing for a treatise on the law of nations. But, on the death of his friend Webster, to whom he had always been closely attached, and of whom he was always a confidential adviser, he was named by President Fillmore secretary of state, and he held that post for the remaining months of Fillmore's administration, leaving it to go into the senate as the representative of Massachusetts. Under the work of the long session of 1853–54, in which that "Kansas-Nebraska" question first appeared in form which ripened into the American civil war, his health gave way. He resigned his seat, on the orders of his physician, and retired to what was called private life.

But, as it proved, the remaining ten years of his life most widely established his reputation and influence throughout America. As early as 1820 he had established a reputation, such as few men in later days have enjoyed, as an orator. He was frequently invited, as other public men are invited in America, to deliver an "oration" on one or another public topic of historical or other interest. With him these "orations," instead of being the ephemeral entertainments of an hour, became careful studies of some important theme, so that the collected edition of them is now one of the standard books of reference in an American's library. Eager to avert, if possible, the impending conflict of arms, Everett prepared an "oration" on Washington, which he delivered in every part of America. In a printed note accompanying the published edition of it, he names nearly one hundred and twenty-five occasions, in almost every State in the Union, in every section but the extreme Southwest, where it was repeated. This exception was caused only by illness in his family, after he had received invitations to go to that quarter also. He travelled really as an ambassador of peace among irritated States. The eagerness to hear him was so great that, from the first, his hosts arranged, almost always, that tickets should be sold to all auditors; and as he travelled wholly at his own charges, the audiences thus contributed more than one hundred thousand dollars for the purchase of the old home of Washington at Mount Vernon, and the securing it as a shrine for American patriotism.

Everett's name, in direct violation to his wishes, was presented, with Mr. Bell's, as a candidate of North and South jointly for vice-president in the election of 1860, when Abraham Lincoln was elected. The civil war followed. Reconciliation was impossible, and he gave all his learning, zeal, and eloquence, to the support of the national government. For four years he was the trusted adviser of every department; he was called upon in every quarter to speak at public meetings. He delivered the last of his great orations at Gettysburg, after the battle, on the consecration of the national cemetery there. In February of 1865 the success of the national arms was certain. He had the pleasure of speaking at a public meeting in Boston to raise funds for the Southern poor in Savannah, just taken by General Sherman. At that meeting he caught cold, which was followed by sudden illness, and by his death January 15, 1865.

In Everett's life and career was a combination of the results of diligent training, unflinching industry, delicate literary tastes, and unequalled acquaintance with modern politics. This combination made him in America an entirely exceptional person. He was never loved by the political managers; he was always enthusiastically received by assemblies of the people. He would have said himself that the most eager wish of his life had been for the higher education of his countrymen. His orations have been collected in four volumes. A work on public law, on which he was engaged at his death, was never finished. (E. E. H.)

EVESHAM, a municipal and parliamentary borough and market town of Worcestershire, England, is situated in the vale of Evesham, 15 miles S.E. of Worcester, on the Midland and Great Western Railways, and on the river Avon, over which there is an ancient stone bridge of eight arches, connecting it with Bengeworth parish, which forms part of the borough. It is a well-built town, and its two main streets are wide and clean. The surrounding land is of great fertility, and is occupied chiefly as market gardens. The inhabitants of the town are mostly employed in the rearing of garden produce, but there are also manufactories for agricultural implements, and for gloves and hosiery. The principal buildings are the old town-hall, the churches of All-Saints, St. Lawrence, and St. Peter's, and the grammar school. Evesham is a place of considerable antiquity, a monastery having been founded there as early as the beginning of the 8th century. Of this building almost the only remnant is a magnificent tower, built not long before the Reformation. This tower, which is considered the best extant specimen in England of the Pointed ecclesiastical style of the 16th century, is 110 feet high and 28 feet square at the base. At Evesham was fought, on the 14th August, 1265, the famous battle between Prince Edward, afterwards Edward I., and Simon de Montfort, earl of Leicester, in which the latter was totally defeated, and he and his son slain. Previous to 1867 Evesham returned two members to parliament, but it now returns only one. The population in 1871 was 4888.

EVIDENCE. It is necessary to distinguish two common meanings of the word evidence which are not unfrequently confused. Evidence sometimes means the ascertained facts from which we infer the existence of some other fact or principle. It also means the testimony of persons as to the existence of facts, from which testimony we infer that these or other facts do or do not exist. It is the latter sense alone which is appropriate in speaking of judicial evidence.[1] The rules of the law of evidence are based chiefly on considerations relating to human testimony. Their fundamental purpose is to guard and test the truthfulness of statements as to matters of fact made in a court of justice. The further question, what conclusion is to be drawn from the facts, supposing them to be true, is the subject of few if any specific rules. The general theory of relevancy excludes testimony relating to facts from which no conclusion whatever could be drawn with reference to the facts in issue. On the other hand, in the case of what is called "conclusive proof," the law directs that on certain evidence the judge must regard some fact as proved and reject any evidence offered against it. Between these two extremes the law leaves the relation between facts in evidence and facts in issue to the unaided logic or common sense of the tribunal.

The theory of relevancy above alluded to lies at the root of the law of evidence, and requires some preliminary explanation. The phrase is not one of common use in English text-books, and nothing like a statement of the general principle is to be found in them. Roscoe, for instance (*Digest of the Law of Evidence at Nisi Prius*), simply states that, "as the object of pleading is to reduce the matters in difference between the parties to distinct and simple issues, so the rules of evidence require that no proof, oral or documentary, shall be received that is not referrible to those issues. All evidence of matters which the courts judicially notice, or of matters immaterial, superfluous, or irrelevant, is therefore excluded." And again, "In general, evidence of collateral facts, not pertinent to the issue, is not admissible." We are left to collect from the abundant wealth of decided cases what things are relevant and material, and what things are irrelevant and superfluous. A statement of the general result of the cases will be found in Sir James F. Stephen's recently published *Digest of the Law of Evidence*. In the introduction to an edition of the Indian Evidence Act, by the same author, the theory of relevancy thus deduced from the decided cases is fully explained, and its connection with the general laws of experimental inquiry pointed out.

The distinction sometimes drawn between direct and circumstantial evidence is of popular rather than legal interest. The fact in issue may be proved either by the testimony of persons who swear to it as a matter of personal knowledge, or by the testimony of persons who swear to other facts from which the existence of the fact in issue is inferred. In the former case the evidence is said to be direct, in the latter circumstantial. The probative force of these two sorts of evidence has been differently estimated. On the one hand, it has been said (and this we should think is the more popular view) that a conclusion arrived at merely from inference is not so trustworthy as the positive assertion of a sane and honest witness who testifies to what he has actually seen or heard. The explanation would seem to be that men have less confidence in their own powers of reasoning than in the assertions of others. It is hardly necessary to point out that in both cases a process of inference is necessary—that we infer the existence of the fact from the fact that the witness swears to it, and that this inference like others is exposed to the chances of error. On the other hand, the numberless instances on which positive direct testimony as to matters of fact has been subsequently shown to be entirely false or erroneous, has led to the opposite opinion that circumstantial is more trustworthy than direct evidence. Apart from the possibility of deliberate falsehood in the witness, there is the chance of his having been utterly and unaccountably mistaken. Everybody can recall striking instances of this—especially in cases of personal identity.[2] Accordingly, it has been said, in the phrase of Paley, that "circumstances cannot lie," or, as it was put by Mr. Justice Buller in Donnellan's case, "a presumption which naturally arises from circumstances is very often more convincing and more satisfactory than any other kind of evidence, because it is not within the reach and compass of human ability to invent a train of circumstances which shall be so connected together as to amount to a proof of guilt without affording opportunities for contradicting a great part, if not all those circumstances." The facts in circumstantial evidence are, however, like the facts in direct evidence, to be taken subject to the possibility of mistake or falsehood in the person narrating them, and the process of inference has its own peculiar dangers. The *anno domini* water-mark on writing-paper has often been the instrument of convicting persons of forgery; but "it is beyond a doubt," says Mr. Wills, "and instances of the kind have recently occurred, that issues of paper have taken place bearing the water-mark of the year succeeding their distribution." Circumstantial evidence corresponds to "facts relevant to the issue," as defined in this article.

---

[1] Sir James Stephen's definition is—"Evidence means—(1) all statements which the judge permits or requires to be made by witnesses in court in relation to matters of fact under inquiry; such statements are called oral evidence; and (2) all documents produced for the inspection of the court or judge: such documents are called documentary evidence."—*Digest of the Law of Evidence*.

[2] A very remarkable example is given by Mr. Wills in his essay on *The Rationale of Circumstantial Evidence*. Sir Thomas Davenant, an eminent barrister, a gentleman of acute mind and strong understanding, swore positively to the persons of two men whom he charged with robbing him in the open daylight. But it was proved, on the most conclusive evidence, that the men on trial were at the time of the robbery at so remote a distance from where Sir Thomas was robbed that the thing was impossible. The consequence was that the men were acquitted; and some time afterwards the robbers were taken, and the articles stolen from Sir Thomas and his lady found upon them.

The English law of evidence is perhaps the most perfect example we possess of what Bentham calls judge-made law. It is substantially the creation of successive generations of judges in the courts of common law. It grew up as a thing of custom and practice, and it is not so very long since different customs prevailed on different circuits. Thus, Lord Ellenborough, in one instance quoted by Sir J. Stephen, spoke of the practice of the Northern and Western Circuits as being different from that of the Oxford Circuit. It was made by judges for juries, and this fact no doubt serves to explain many of its peculiarities. Without adopting Bentham's opinion that these were deliberately intended to subserve the "sinister interests" of the lawyers, we may admit that they were founded largely on distrust of the capacity of the tribunal to which the issues of fact belong. Hence doubtless those numberless presumptions by which a conclusion is imposed on the jury until positive evidence is offered to set it aside. Hence also that monstrous system of exclusions by which any person whose position was such as to make it in the least degree likely or possible that he would tell a falsehood, was withdrawn from the hearing of the jury. Only the most contemptuous disbelief in the sagacity of jurymen can account for the exclusion of the only witness cognizant of the transaction in question, simply because he has a slight pecuniary interest in the result. It may be conjectured that if trial by jury had not been the practice of the common law—if the judges had acquired the power of deciding issues of fact as well of law—many of the most obnoxious rules of evidence would never have existed.

The legislature has interfered mainly for the purpose of putting an end to these exclusions. Certainly the most important of the statutes dealing with the law of evidence are those which make classes of persons, formerly excluded, competent to testify. The source of this continuous reform is to be found in the treatise of Bentham, which, for the first time, examined the traditionary law by the light of practical utility. Starting with the fundamental principle that the great object in judicial evidence is the discovery of truth, he hunted down with merciless rigor the artificial rules which closed out the surest sources of evidence. The success of his attack has been complete. In 1843 the exclusion of persons by reason of interest or crime was abolished (6 and 7 Vict. c. 85), but the incapacity of the parties to an action was allowed to remain. This in turn was abolished with certain exceptions by the 14 and 15 Vict. c. 99. By 32 and 33 Vict. c. 68, parties were allowed to give evidence in actions for breach of promise (subject to the requirement of corroboration), and husbands and wives in proceedings for adultery. The last Act of this sort was passed in 1877, and is a curious instance of the guarded way in which the legislature has approached this subject. It simply provides that, on the trial of any indictment or other proceeding for the non-repair of any public highway, bridge, or for a nuisance, or of any other indictment or proceeding instituted for the purpose of trying or enforcing a civil right only, every defendant to such indictment or proceeding, and the wife or husband of any such defendant, shall be admissible witnesses, and compellable to give evidence. Husband and wife are now excluded only in purely criminal cases, and in course of time no doubt that exclusion also will be brought to an end. Religious disabilities (enforced by the necessity of an oath) have also been gradually got rid of by successive enactments, the most important being the 24 and 25 Vict. c. 66, and 32 and 33 Vict. c. 68. With these exceptions, the legislature has left the leading principles of the law untouched.

In attempting to give an outline of the law of evidence in this country we shall follow in the main the division adopted by Sir J. Stephen in his very useful *Digest*. English text-books on the law of evidence owe their enormous bulk to the introduction of rules which properly belong to the substantive law, or to the rules of practice in the tribunals. Confining ourselves to the general principles of evidence, we shall notice shortly the following heads:—1st, What facts may be proved in a court of law; 2d, By what kind of evidence they must be proved; and 3d, By whom, and in what manner, the evidence must be produced.

1. Sir J. Stephen states the general rule as follows:—"Evidence may be given in any action of the existence or non-existence of any fact in issue, and of any fact relevant to any fact in issue, and of no others." Relevant facts here means simply facts (other than those in issue) which may be proved, and would include cases of relevancy strictly so-called,—*i.e.*, facts relevant in the sense that from their existence you may infer the existence of the facts in issue. There are minor classes of facts, not being facts in issue, and not being relevant facts in this sense, which nevertheless may be proved. For example, "facts which, though not in issue, are so connected with facts in issue as to form part of the same transaction," and "facts which are necessary to be known to explain or introduce a fact in issue," may be proved; but to say that they are relevant tends to obscure the theory of relevancy.[1]

What facts, then, are to be regarded as relevant to facts in issue? English law, as we have seen, makes no attempt to answer this question otherwise than by the enumeration of decided cases. The general definition of relevancy in Stephen's *Digest* is the following:—Facts, whether in issue or not, are relevant to each other when one is, or probably may be, or probably may have been—the cause of the other, the effect of the other, an effect of the same cause, a cause of the same effect,—or when the one shows that the other must or cannot have occurred, or probably does or did exist, or that any fact does or did exist or not, which in the common course of events would either have caused or have been caused by the other.[2]

There is little doubt that this is a correct statement of the general principle embodied in the decided cases of the law of England. Facts may be proved from which legitimate inferences may be drawn as to the existence of the facts disputed at the trial, and this inference depends on the existence of a causal connection between the two sets of facts. The theory of relevancy thus becomes, as Sir James Stephen (Indian Evidence Act) has pointed out, a particular case of the general theory of induction; and the question whether facts are relevant to each other or not may become co-extensive with the entire field of human knowledge. Bentham has pointed out, in his chapter on "Real evidence, or evidence from things" (*Rationale of Judicial Evidence*, book v. c. 3), that

> "There is scarce an imaginable distinction or observation an indication of which could, with reference to the subject of the present work, be charged with being altogether irrelevant; for in one way or other, and even in each instance in various ways, there is not an imaginable fact the existence of which is not capable of being taken for the subject of inquiry in a court of judicature. If, therefore, the whole encyclopædia were to be crowded into the body of this work, and into this part of it in particular, there is not a page of it that would, strictly speaking, be irrelevant with regard to the subject of this work."

It is perhaps hardly necessary to give instances in illustration of the general definition of things relevant. The conduct of a person charged with an offence is one of the most common and the most obvious cases. Thus, "any fact which supplies a motive for such an act, or which constitutes preparation for it, any subsequent conduct of such person which appears to have been influenced by any such act, and any act done in consequence of any such act by or by the authority of that person," may obviously lead to inferences as to the act itself. One of Sir James Stephen's illustrations may be cited:—

---

[1] In a later edition of the *Digest*, the phrase "deemed to be relevant" is substituted for "relevant."

[2] This definition is borrowed from a pamphlet on the *Theory of relevancy for purposes of judicial evidence*, by George Clifford Whitworth, Bombay, 1875. Mr. Whitworth examines the case of Müller, tried at the Old Bailey in 1864, and shows how the items of evidence admitted fall under one or other of the above heads of relevancy.

> "The question is whether A wrote an anonymous letter threatening B, and requiring B to meet the writer at a certain time and place to satisfy his demands. The fact that A met B at that time and place is relevant, as conduct subsequent to and affected by a fact in issue (an effect of that cause). The fact that A had a reason unconnected with his letter is relevant as rebutting the inference suggested by his presence (the effect of another cause)."

The limit of relevancy is sometimes expressed by the saying that collateral facts are not admissible in evidence unless pertinent to the issue, but, as usual, we are left to collect the meaning of collateral from the decided cases. The typical case is perhaps that of Holcombe *v.* Hewson (2 Campbell, 391), where, on a question whether the beer supplied by plaintiff to defendant was good, the plaintiff was not allowed to prove that the beer he supplied to his other customers was good. In Phillips *On Evidence* it is stated that an admission by a prisoner that he had committed a similar offence at another time ought not to be received in evidence. To an enumeration of such cases Roscoe (*Evidence at Nisi Prius*, p. 89) adds generally that all proof of facts which merely tends to create an unjust prejudice, or unduly to influence the jury, or occupy the time of the court in irrelevant inquiries, is inadmissible; but if the proof be directly or indirectly pertinent to the issue, it will be admitted;—which seems to come to this, that mere similarity in circumstances or coincidence in time will not make one fact relevant to another unless some causal connection between them is made apparent. Thus, in the beer case above mentioned, the evidence might have been made relevant by showing that the beer supplied to all the customers was the same. Sir James Stephen's *Digest* contains several headings of exceptions to the rule excluding collateral evidence, but they will be found, we think, to be all cases of the general rule of relevancy. Some bond of connection, as cause and effect, will be found to have been established between them. Thus, when the intention of an act is in question (as in the case of a man accused of setting fire to his house in order to get insurance money), other instances of similar acts (as that the prisoner had previously had two houses burnt, each being insured, and the insurance having been paid) may be adduced.

But it must not be supposed that the law admits as evidence all facts which are, in a strictly logical sense, relevant. The most considerable and important exception is that of *hearsay evidence.* In ordinary life we should regard a statement made to us at second hand not only as relevant to the fact it asserts, but as sufficient and satisfactory proof, if both of our informants are persons of creditable character and intelligence. In point of fact, the immense bulk of our knowledge and belief on all sorts of subjects is founded on hearsay evidence, many times more remote than in the case we have supposed. The general rule of law excludes all such evidence. "The fact that a statement was made by a person not called as a witness is not regarded as relevant to the truth of the matter asserted thereby." The reason is sufficiently obvious. A deponent in court tells his story under securities for its truthfulness. He may be cross-examined. He may be punished for telling lies. But for these securities it would hardly be safe, considering the consequences attaching to every issue in a court of justice, to act upon any testimony whatever. These securities do not exist in the case of extra-judicial statements by persons not called before the court, and accordingly, as a general rule, no evidence can be offered regarding them. The extent, and perhaps the apparent severity of the rule, may be illustrated by the case in which it was held that, in a question of the validity of a will, the declaration of one attesting witness, since deceased, that he forged it, cannot be offered in evidence.

This rule, however, has its exceptions, which are classified in Stephen's *Digest* under the heads of "admissions or confessions; statements by deceased declarant; evidence given on a former occasion; statements made under special circumstances; judgments of a court of justice." An admission is defined to be a statement suggesting any inference as to facts unfavorable to the conclusion contended for by the person by whom or on whose behalf it is made, and may be given in general in evidence against him. In civil actions, statements of this sort, made without prejudice or on express condition that they are not to be used in evidence, may not be admitted. An important class of admissions is that of confessions in criminal cases. A voluntary confession may be used in evidence against a prisoner, but a confession caused by "any inducement, threat, or promise, proceeding from a person in authority," is not admissible. But a confession made under promise of secrecy, or in consequence of deception, may be used in evidence. Dying declarations, made in immediate prospect of death, are admissible in trials for the murder or manslaughter of the deceased. Declarations made in the ordinary course of business or duty by deceased persons are admitted as relevant to the matter to which they relate. And a declaration by a deceased person is admissible "if he had peculiar means of knowing the matter stated, if he had no interest to misrepresent, and if it was opposed to his proprietary interest."[1] Declarations relating to public rights or customs by competent persons may be used in evidence after their death. In pedigree cases, statements by deceased blood-relations, made before litigation, are to be admitted. The statutes 11 and 12 Vict. c. 42 and 30 and 31 Vict. c. 35 allow depositions of deceased witnesses to be used in certain criminal cases. In civil cases the evidence of a deceased witness may be used at a subsequent trial raising the same issues. Among the miscellaneous cases of admissible hearsay evidence may be mentioned facts of a public nature recited in statutes and proclamations, entries in public records, and statements in maps, and plans, and accredited historical works. Judgments are conclusive proof of "the state of things which they effect," and as between parties of the facts actually in issue.

Another instance of departure from the logical theory of relevancy is the evidence of opinion. The general rule, as enunciated by Stephen (*Digest*, part i. c. 5), is "that the fact that any person is of opinion that a fact in issue or relevant to the issue does or does not exist is not regarded as relevant to the existence of such fact." A distinction, which Sir J. Stephen does not notice, must be drawn between two senses in which the word opinion may be used. In common parlance, the belief of a scientific witness on some technical point, and the belief of an ordinary witness as to some fact perceived by himself, would with equal propriety be described as opinion. And it would not be difficult to show that psychologically they are the same thing. The opinion in each case is the result of a process of reasoning. In each case one reasons from a number of facts to a conclusion. The belief of a witness in a question of personal identity is based on a number of facts as to which he has no doubt, *e.g.*, the size, the build, the gait, the clothes, of the person in question. The law, however, draws a broad distinction between this kind of inference and the open and deliberate inference as to matters not directly perceived by the senses. It distinguishes between facts and inferences, holding in disregard of psychology that the former are directly perceived; but it does not insist upon absolute certainty in the perception. A witness may "believe" or "think" or "be of opinion" that he saw A. on a given day, or he may say positively that he did see him. The strength of his persuasion will be considered by the tribunal, but his evidence will not be rejected because his persuasion is weak. Or, as Mr. Taylor puts it, "the law does not require him to speak with such expression of certainty as to exclude all doubt." By opinion then is meant not merely a lower degree of persuasion, a more feeble belief, but a belief held as the result of inference and not of direct perception. There is nothing in the feebleness with which a witness's belief in the existence of a fact is expressed or held to make it irrelevant. But as a general rule, opinion in the other sense is not admissible in evidence at all. It is the business of the tribunal of the jury to form such opinions for themselves. Indeed, the exclusion of opinion in evidence is put on this very ground in some of the decided cases. Thus, in an insurance case, a new trial was granted because the opinion of a witness had been admitted as to whether the communication of particular facts would have varied the terms of the policy—the court holding that this was a question for the jury alone. But the general rule has its exceptions, which may almost all be included "in the opinion of experts." In matters of science and skill requiring special study and education, the opinion of persons so qualified (experts) may be given in evidence. The law of a foreign country, and the examination of hand-writing, are among such matters. But an expert cannot give an opinion as to the existence of the facts on which his opinion is based, although of course he may testify to them if he has perceived them himself. In thus excluding opinion on all but technical subjects, the law is stricter than the logic of ordinary life. The opinion of others tells for something in the formation of our own opinions, and no doubt ought to tell for something. This, however, is not the place for an examination of the influence of authority in matters of reasoning. It is sufficient to point out that in law it is reduced to a minimum.

---

[1] In the leading case of Higham *v.* Ridgway, an entry in the book of a deceased man-midwife, stating the birth of a child on a certain day and the *payment* of his fee for attendance, was admitted in evidence to prove the birth on that day. The acknowledgment of payment was held to be "against the declarant's interest," and rendered the whole statement admissible. The distinctions made by judges in cases of declarations by persons deceased run very fine. A declaration made by a person in the course of his business or duty will not let in anything but the statement it was his duty to make. Thus a declaration by a deceased sheriff's officer as to the time and place of an arrest effected by him was admitted so far only as the *time* was concerned, because it was not his official duty to make a note of the *place.* If, however, the statement had contained such a note as "received for the same five shillings" (which would be a statement against interest), the evidence as to place would have been admitted. Again, in the Sussex Peerage case, it was held that a declaration made by a clergyman that he had performed a marriage under circumstances which would make him liable to pecuniary penalties was held not to be a "statement against interest" within the meaning of the rule. On the other hand, a statement made by a tenant that he paid rent for his house was held to be admissible as against interest, because it rebutted the presumption founded on the fact of possession that it belonged to him in fee simple. The tendency of judicial decisions since the principal case (Higham *v.* Ridgway) has been to limit the operation of the rule. In a recent case, however (Leyden *v.* Lord St. Leonards), the judges expressed an opinion that the best rule would be to admit all declarations made by deceased persons, where they had peculiar means of knowing the fact testified, and had no interest to misrepresent it.

2. *How facts that may be given in evidence are to be proved.*—First of all we must set aside a considerable class of facts which need not be proved, because they are already supposed to be known to the court. The judge takes "judicial notice" of them. These are for the most part facts relating to the constitution, including, of course, the entire body of law administered in all the courts of the country, from whatever source it may be derived. The courts will also take judicial notice of the accession and sign manual of the queen and her successors, of the existence and title of every state and sovereign recognized by her majesty, of the names, titles, functions, signatures, etc., of the judges of the supreme court, of the great seal, privy seal, seals of the courts of justice, and of certain corporations, *e.g.*, of London, of the universities, also of the beginning and termination of war, and the articles of war, the extent of her majesty's dominions, the divisions of time, the meaning of English words, etc. (see Stephen's *Digest*, pt. ii. c. 7). And, of course, facts which have been admitted for the purposes of the trial by the parties or their agents need not be proved. All other facts must be proved, either by oral or documentary evidence. Oral evidence is the testimony of a witness delivered before the court as to what he has himself actually seen or heard. All facts *may* be proved by oral evidence, except in some special cases where the law requires documentary evidence. A "document," in this sense, extends to any record, whether expressed in writing or symbols, and no matter what may be the nature of the substance on which it is recorded. A gold watch with an inscription on it, or a tombstone, is a document.

The most important rule in this branch of the subject is that which requires the contents of a document to be proved by the document itself. The law requires the "best evidence" procurable in each case, and if a document is in existence it is better evidence than any second-hand account of its contents. This is called primary evidence. But secondary evidence, either by means of written copies or oral accounts, is to be admitted in certain cases. If it is proved that the instrument has been lost or destroyed, or that it is in the hands of the opposite party, who, after notice, has refused to produce it, then "secondary" evidence of its contents may be given. So when the original is of such a nature that it cannot be easily moved (as, *e.g.*, a libel written on a wall), secondary evidence may be given. Secondary evidence includes (besides oral accounts by persons who have seen the original)—(1) examined copies, exemplifications, office copies, and certified copies; (2) other copies made from the original and proved to be correct; (3) counterparts of documents as against the parties who did not execute them (Stephen, *Digest*, part ii. c. 9). Public documents in general must be proved either by the production of the original or by the official copies in class (1) above. Stephen states the rule requiring documentary evidence in special cases as follows: "When any judgment of any court or any other judicial or official proceeding, or any contract or grant, or any other disposition of property, has been reduced to the form of a document or a series of documents, no evidence may be given except the document itself, or secondary evidence" where such is admissible. The importance of this rule with reference to contracts will be at once apparent. When the contract has been reduced to writing, parole (or oral) evidence cannot be admitted to prove its contents. The writing itself, or secondary evidence, must be produced, and no variation of its terms can be proved by oral evidence. Thus, where goods were insured generally in ships from a particular port, and the ship in which they were shipped was lost, evidence could not be given that that particular ship was excepted from the policy. The mere fact that a memorandum was made, not intended to have effect as a contract, will not exclude oral evidence of the transaction. And certain facts, collateral to the contract, may be proved by oral evidence. Thus fraud, or want of consideration, or any circumstances which would affect its validity, may be so proved.

Of course, in the interpretation of contracts containing doubtful, technical, or unintelligible expressions, or using common words in a non-natural sense, recourse must be had to oral evidence. Thus the expression a "bale of gambier," in a written contract, may be proved by verbal evidence to mean a compressed package weighing two cwt. And where the expression "ten thousand rabbits" occurred in a lease, evidence to show that a thousand, in relation to rabbits, meant twelve hundred was admitted. But when the document is utterly unmeaning (as where a legacy is left to ———), oral evidence cannot be resorted to for the purpose of supplying a meaning. Where more than one meaning is possible, reference may be to the surrounding circumstances, or the fact to which the document was or may have been intended to refer. These rules, it need hardly be said, apply only as between parties, and where the legal rights and obligations dependent on the instrument are in question.

Certain presumptions (*i.e.*, conclusions of fact adopted until they are disproved) relating to documents may be mentioned here. Thus a document is presumed to have been executed on the day on which it bears date. Again, where a document is not produced after due notice, it is presumed to have been duly stamped. And it is a most important presumption with reference to documents purporting and proved to be thirty years old, and produced from what appears to be the proper custody, that the signatures, execution, and attestation are as they purport to be. Or, as it is sometimes expressed, "when a deed is thirty years old, it proves itself." Alterations and interlineations in a deed are presumed to have been made before execution; in a will they are presumed to have been made afterwards. The nature of such presumptions is explained below.

One more rule with regard to documentary evidence may be added. When the law requires an instrument to be attested (*e.g.*, a will), it cannot be used in evidence unless one attesting witness is called to prove its execution, if there be an attesting witness alive and capable of giving evidence. If there be no such witness, the signature of at least one attesting witness, and of the person executing the deed, must be proved to be in their respective handwritings. This rule was said by Lord Ellenborough to be as "fixed, formal, and universal as any that can be stated in a court of justice." It formerly extended to all documents actually attested, not merely to those required to be attested by law.

3. *Burden of proof, competency of witnesses, etc.*—The general rule is that the burden of proof lies on the person who asserts the affirmative, or, as it is more accurately expressed by Sir J. Stephen, "whoever desires any court to give judgment, as to any legal right or liability dependent on the existence or non-existence of facts which he asserts or denies to exist, must prove that these facts do or do not exist." And the burden of proof, and the right of beginning in an action, lie on the party against whom judgment would be given if no evidence at all were offered in the case. Again, the effect of a presumption (*presumptio facti*, as distinguished from *presumptio juris* or conclusive proof) is to throw the burden of proof on the party who denies it as a matter of fact. And here it may be convenient to say a word or two with reference to presumptions. Writers on the law of evi-

dence generally distinguish between presumptions of law and presumptions of fact—the latter being, the former not being, rebuttable by counter-evidence. The subject occupies a considerable space in most books on evidence. Sir J. Stephen regards it as falling properly under specific divisions of the substantive law. Thus the presumption that everybody knows the law he regards as belonging to the criminal law and not to the law of evidence. Presumptions of this sort (*presumptiones juris et de jure*) are an indirect way of expressing some legal principle. In the last case the rule is that ignorance of the law is no excuse for an illegal act, and the so-called presumption looks like an artificial and characteristic reason invented for its explanation. Presumptions of fact, *i.e.*, conclusions which on certain evidence must be adopted by the court until and unless they are disproved by counter-evidence, are cases in which the task of inference is taken out of the hands of the jury altogether. They are strongly objected to by Bentham (*Rationale of Judicial Evidence*, Introduction, c. 22) on this very ground. "On trial for a criminal offence, amongst others murder, in this and that case the law presumes malice. Of the presumption in this case, what is the plain English? That fearing that by a jury the man would be acquitted, the determination of the judge is that he shall be convicted." If the presumption, however, is the safest conclusion to act on in the circumstances, there would seem to be no harm in saving the jury the trouble of drawing the inference for themselves.

Besides these two classes of presumptions, and along with them, legal writers often discuss the presumptions which are said to be within the province of the jury itself. These are neither more nor less than various degrees of probability in cases of circumstantial evidence; thus the leading text book on criminal practice (Archbold), following Coke and Blackstone, states that these presumptions are of three kinds—*violent, probable,* and *light* or *rash.* A case of violent presumption, generally given as an illustration, is where a person is found in a house run through the body, and a man is seen running away with a drawn sword in his hand, no other person being found about the premises. The conclusion that this man is the murderer is irresistible. The other cases are simply inferior degrees of probability established by circumstantial evidence, the lowest degree being described as such that it ought to have no weight with us at all. The distinctions are of no value, and are probably retained in text-books because they are described by the same name as the two classes of legal presumptions above described—those, namely, which Sir J. Stephen distinguishes as "conclusive proof" and "presumption," respectively.

Presumptions of the second class abound in every branch of the law, and are to be explained with reference to its peculiar principles. Of the more general presumptions a number of examples have been collected in Stephen's *Digest,* part iii. c. 14. One of the most common is the presumption of death after seven years' absence, which has been a good deal debated in the courts, but may now be considered to be settled. A person who has not been heard of for seven years is presumed to be dead, unless the circumstances are such as to account for his absence otherwise. But there is no presumption as to his having been dead at any particular time, *e.g.*, if a person was last heard of in 1860, the court in 1870 presumes that he is dead, but not that he was dead in 1867. The question of survivorship, where two or more persons are shown to have perished by the same catastrophe, as in cases of shipwreck, has been much discussed. It was at one time thought that there might be a presumption of survivorship in favor of the younger as against the older, of the male as against the female, etc. But it is now clear that there is no such presumption. Another common case is the presumption of legitimacy in favor of persons born during the continuance of lawful wedlock. The presumption of regularity in official proceedings (*omnia esse rite acta*) is also one of frequent occurrence.

The effect of presumptions may be compared with that of estoppel. The former establishes against a party a conclusion which stands unless and until he positively disproves it. By estoppel a party is prevented from disproving a fact which he has actually or constructively asserted. For examples see article Estoppel.

With few exceptions all witnesses are now competent to testify in courts of justice. The following are the chief exceptions:—(1) persons incapacitated by extreme youth, or mental disease; and (2) in criminal cases the wife or husband of a prisoner, except when the prosecution is for injury or violence to such wife or husband. The old rules of exclusion have been noticed *supra.*

Certain classes of facts are protected from disclosure on various grounds. Thus, no person can be compelled to disclose communications made to him by his wife during marriage, and servants of the state cannot be compelled to give evidence in official matters without the consent of the head of the department to which they belong. But perhaps the most important case is that of communications between lawyer and client. The lawyer is not allowed to disclose such communications without the client's assent, nor can the client be compelled to disclose such communications himself. The rule, however, will not extend to communications in furtherance of any crime or fraud. Medical men and clergymen have no such privilege. There is, however, a general consensus of opinion in favor of protecting confessions made by prisoners to their spiritual advisers; and judges have from time to time expressed their reluctance to compel disclosure in such cases. To this class also belongs the rule that no person can be compelled to answer a question tending to criminate himself, although the fact that the answer might expose him to a civil action will be no protection.

In some few cases the evidence of more than one witness is required. Thus, in trials for treason, there must be at least two witnesses testifying to the same act or to different acts of the same treason, except when the treason consists in an attempt on the life or person of the queen. So in perjury, one witness, unless corroborated by circumstances, will not be sufficient to convict the prisoner. In actions for breach of promise of marriage, in affiliation cases, and in prosecutions when the only witness is an accomplice, such corroboration is also necessary. Otherwise in the law of England the testimony of one witness is sufficient to prove any fact.

The general rule is that testimony must be given on oath, but an oath is binding if administered in any form which the witness declares to be binding. By recent enactments, however, a person objecting on grounds of religious belief to the taking of any oath may be permitted to make a solemn affirmation instead; and any person who objects to take an oath, whether on religious grounds or not, or is objected to as incompetent to take an oath, may "solemnly promise and declare." In all cases the punishment of perjury attaches.

At the trial a witness is first of all examined by the party producing him (examination-in-chief); he is then cross-examined by the opposite party, and re-examined by his own party. The re-examination must refer to matters arising out of the cross-examination. There are certain questions which may be asked in cross-examination only. Thus, in the examination-in-chief, leading questions (*i.e.*, questions suggesting their own answer) are not allowed; in cross-examination they are. So also in cross-examination a witness may be asked any question tending to test his accuracy or credibility, or to destroy his credit by injuring his character, and he must answer them, however disgraceful may be the imputation they convey.[1] No evidence, however, can be led to contradict the answer in the latter case, unless it refer to a previous conviction, or to circumstances tending to throw doubt on the impartiality of the witness. A witness may in cross-examination, and a witness proving hostile or adverse to the party calling him, may, in examination-in-chief, be asked whether

[1] The unlimited license of cross-examination to character is the one flagrant abuse of the existing law of evidence; and but for the restraint imposed upon counsel, partly by public partly by professional opinion, would be a much more serious evil than it is. The illustration in Stephen's *Digest* is a notorious but perfectly fair example. "The question is whether A. committed perjury in swearing that he was R.T. B. depones that he made tattoo marks on the arm of R. T., which at the time of the trial were not and never had been on the arm of A. B. may be asked and compelled to answer the question, whether many years after the alleged tattooing, and many years before the occasion on which he was examined, he committed adultery with the wife of one of his friends." The Indian Evidence Act restricts the license of cross-examination by the following provisions:—(1) Such questions are proper if they are of such a nature that the truth of the imputation would seriously affect the opinion of the court as to the credibility of the witness on the matter to which he testifies; (2) Such questions are improper if the imputation would not affect, or would affect in a slight degree, the opinion of the court as to the credibility of the witness on the matter to which he testifies; (3) Such questions are improper if there is a great disproportion between the importance of the imputation made against the witness's character and the importance of his evidence."

he had not on a former occasion made statements inconsistent with his present statements. The credit of a witness may also be impeached by other the party calling witnesses to swear that they believe him to be unworthy of belief, and counter-evidence may be given in reply. The theory of the proceedings is that a witness will tell his story in the most favorable way for the party calling him and against his opponent.

The improper admission or rejection of evidence was formerly a frequent ground for applications for new trial; under the Judicature Act a new trial will only be granted on such ground when some substantial wrong has been occasioned thereby.

The following are the most important writers on the law of evidence:—John Pitt Taylor (two vols. 8vo, 6th edition, London, 1872); Henry Roscoe (*Digest of the Law of Evidence on the trial of actions at Nisi Prius*, 13th edition, by Day and Powell, London, 1875); A. M. Best (*On the Principles of the Law of Evidence, with elementary rules for the interrogation of witnesses*, 6th edition, London, 1875); Edmund Powell (*Principles and Practice of the Law of Evidence*, 4th edition, London, 1875); Sir J. F. Stephen (*Digest of the Law of Evidence*, London, 1877); S. Greenleaf (*On the Law of Evidence*, 3 vols. 13th edition, Boston, 1876). (E. R.)

EVOLUTION. I. Evolution in Biology.—In the former half of the 18th century, the term "evolution" was introduced into biological writings, in order to denote the mode in which some of the most eminent physiologists of that time conceived that the generation of living things took place; in opposition to the hypothesis advocated, in the preceding century, by Harvey in that remarkable work[1] which would give him a claim to rank among the founders of biological science, even had he not been the discoverer of the circulation of the blood.

One of Harvey's prime objects is to defend and establish, on the basis of direct observation, the opinion already held by Aristotle, that, in the higher animals at any rate, the formation of the new organism by the process of generation takes place, not suddenly, by simultaneous accretion of rudiments of all or the most important of the organs of the adult; nor by sudden metamorphosis of a formative substance into a miniature of the whole, which subsequently grows; but by *epigenesis*, or successive differentiation of a relatively homogeneous rudiment into the parts and structures which are characteristic of the adult.

> "Et primò, quidem, quoniam per *epigenesin* sive partium superexorientium additamentum pullum fabricari certum est; quænam pars ante alias omnes exstruatur, et quid de illa ejusque generandi modo observandum veniat, dispiciemus. Ratum sane est et in ovo manifestè apparet quod *Aristoteles* de perfectorum animalium generatione enuntiat: nimirum, non omnes partes simul fieri, sed ordine aliam post aliam; primùmque existere particulam genitalem, cujus virtute postea (tanquam ex principio quodam) reliquæ omnes partes prosiliant. Qualem in plantarum seminibus (fabis, putà, aut glandibus) gemmam sive apicem protuberantem cernimus, totius futuræ arboris principium. *Estque hæc particula velut filius emancipatus seorsumque collocatus, et principium per se vivens; unde postea membrorum ordo describitur; et quæcunque ad absolvendum animal pertinent, disponuntur.*[2] Quoniam enim *nulla pars se ipsam generat; sed postquam generata est, se ipsam jam auget; ideo eam primùm oriri necesse est, quæ principium augendi contineat (sive enim planta, sive animal est, æque omnibus inest quod vim habeat vegetandi, sive nutriendi)*,[3] simulque reliquas omnes partes suo quamque ordine distinguat et formet; proindeque in eadem primogenita particula anima primario inest, sensus, motusque, et totius vitæ auctor et principium." (*Exercitatio* 51.)

Harvey proceeds to contrast this view with that of the "Medici," or followers of Hippocrates and Galen, who, "badly philosophizing," imagined that the brain, the heart, and the liver were simultaneously first generated in the form of vesicles; and, at the same time, while expressing his agreement with Aristotle in the principle of epigenesis, he maintains that it is the blood which is the primal generative part, and not, as Aristotle thought, the heart.

In the latter part of the 17th century, the doctrine of epigenesis thus advocated by Harvey was controverted on the ground of direct observation by Malpighi, who affirmed that the body of the chick is to be seen in the egg before the *punctum sanguineum* makes its appearance. But from this perfectly correct observation a conclusion which is by no means warranted was drawn; namely, that the chick as a whole really exists in the egg antecedently to incubation; and that what happens in the course of the latter process is no addition of new parts, "alias post alias natas," as Harvey puts it, but a simple expansion or unfolding of the organs which already exist, though they are too small and inconspicuous to be discovered. The weight of Malpighi's observations therefore fell into the scale of that doctrine which Harvey terms metamorphosis, in contradistinction to epigenesis.

The views of Malpighi were warmly welcomed on philosophical grounds by Leibnitz,[4] who found in them a support to his hypothesis of monads, and by Malebranche,[5] while, in the middle of the 18th century, not only speculative considerations, but a great number of new and interesting observations on the phenomena of generation, led the ingenious Bonnet, and Haller,[6] the first physiologist of the age, to adopt, advocate, and extend them.

Bonnet affirms that, before fecundation, the hen's egg contains an excessively minute but complete chick; and that fecundation and incubation simply cause this germ to absorb nutritious matters, which are deposited in the interstices of the elementary structures of which the miniature chick, or germ, is made up. The consequence of this intussusceptive growth is the "development" or "evolution" of the germ into the visible bird. Thus an organized individual (*tout organisé*) "is a composite body consisting of the original, or *elementary*, parts and of the matters which have been associated with them by the aid of nutrition;" so that, if these matters could be extracted from the individual (*tout*), it would, so to speak, become concentrated in a point, and would thus be restored to its primitive condition of a *germ;* "just as, by extracting from a bone the calcareous substance which is the source of its hardness, it is reduced to its primitive state of gristle or membrane."[7]

"Evolution" and "development" are, for Bonnet, synonymous terms; and since by "evolution" he means simply the expansion of that which was invisible into visibility, he was naturally led to the conclusion, at which Leibnitz had arrived by a different line of reasoning, that no such thing as generation, in the proper sense of the word, exists in nature. The growth of an organic being is simply a process of enlargement, as a particle of dry gelatine may be swelled up by the intussusception of water; its death is a shrinkage, such as the swelled jelly might undergo on dessication. Nothing really new is produced in the living world, but the germs which develop have existed since the beginning of things; and nothing really dies, but, when what we call death takes place, the living thing shrinks back into its germ state.[8]

[4] "Cependant, pour revenir aux formes ordinaires ou aux âmes matérielles, cette durée qu'il leur faut attribuer, à la place de celle qu'on avoit attribuée aux atomes pourroit faire douter si elles ne vont pas de corps en corps; ce qui seroit la métempsychose, à peu près comme quelques philosophes ont cru la transmission du mouvement et celle des espèces. Mais cette imagination est bien éloignée de la nature des choses. Il n'y a point de tel passage; et c'est ici où les transformations de Messieurs Swammerdam, Malpighi, et Leewenhoek, qui sont des plus excellens observateurs de notre tems, sont venues à mon secours, et m'ont fait admettre plus aisément, que l'animal, et toute autre, substance organisée ne commence point lorsque nous le croyons, et que sa generation apparente n'est qu'une développement et une espèce d'augmentation. Aussi ai je remarqué que l'auteur de la *Recherche de la Verité*, M. Regis, M. Hartsoeker, et d'autres habiles hommes n'ont pas été fort éloignés de ce sentiment." Leibnitz. *Système nouveau de la Nature*, 1695. The doctrine of "Emboîtement" is contained in the *Considérations sur le principe de vie*, 1705; the preface to the *Theodicée*, 1710; and the *Principes de la Nature et de la Grace* (§ 6), 1718.

[5] "Il est vrai que la pensée la plus raisonable et la plus conforme à l'experience sur cette question très difficile de la formation du fœtus; c'est que les enfans sont déja presque tout formés avant même l'action par laquelle ils sont conçus; et que leurs mères ne font que leur donner l'accroissement ordinaire dans le temps de la grossesse." *De la Recherche de la Verité*, livre ii. chap. vii. p. 334, 7th ed., 1721.

[6] The writer is indebted to Dr. Allen Thomson for reference to the evidence contained in a note to Haller's edition of Boerhaave's *Prælectiones Academicæ*, vol. v. pt. ii. p. 497, published in 1744, that Haller originally advocated epigenesis.

[7] *Considérations sur les Corps organisés*, chap. x.

[8] Bonnet had the courage of his opinions, and in the *Palingénésie Philosophique*, part vi. chap. iv., he devolves a hypothesis which he terms "évolution naturelle;" and which, making allowance for his peculiar views of the nature of generation, bears no small resemblance to what is understood by "evolution" at the present day:—

"Si la volonté divine a créé par un seul Acte l'Universalité des êtres, d'où venoient ces plantes et ces animaux dont Moyse nous decrit la Production au troisieme et au cinquieme jour du renouvellement de notre monde?

"Abuserois-je de la liberté de conjectures si je disois, que les Plantes et les Animaux qui existent aujourd'hui sont parvenus par une sorte d'evolution naturelle des Etres organisés qui peuplaient ce

The two parts of Bonnet's hypothesis, namely, the doctrine that all living things proceed from pre-existing germs, and that these contain, one inclosed within the other, the germs of all future living things, which is the hypothesis of "*emboîtement;*" and the doctrine that every germ contains in miniature all the organs of the adult, which is the hypothesis of evolution or development, in the primary senses of these words, must be carefully distinguished. In fact, while holding firmly by the former, Bonnet more or less modified the latter in his later writings, and, at length, he admits that a "germ" need not be an actual miniature of the organism; but that it may be merely an "original preformation" capable of producing the latter.[1]

But, thus defined, the germ is neither more nor less than the "particula genitalis" of Aristotle, or the "primordium vegetale" or "ovum" of Harvey; and the "evolution" of such a germ would not be distinguishable from "epigenesis."

Supported by the great authority of Haller, the doctrine of evolution, or development, prevailed throughout the whole of the 18th century, and Cuvier appears to have substantially adopted Bonnet's later views, though probably he would not have gone all lengths in the direction of "emboîtement." In a well-known note to Laurillard's *Éloge*, prefixed to the last edition of the *Ossemens fossiles*, the "radical de l'être" is much the same thing as Aristotle's "particula genitalis" and Harvey's "ovum."[2]

Bonnet's eminent contemporary, Buffon, held nearly the same views with respect to the nature of the germ, and expresses them even more confidently.

> "Ceux qui ont cru que le cœur étoit le premier formé, se sont trompés: ceux qui disent que c'est le sang se trompent aussi: tout est formé en même temps. Si l'on ne consulte que l'observation, le poulet se voit dans l'œuf avant qui'il ait été couvé."[3]
>
> "J'ai ouvert une grande quantité d'œufs à differens temps avant et après l'incubation, et je me suis convaincu par mes yeux que le poulet existe en entier dans le milieu de la cicatrule au moment qu'il sort du corps de la poule."[4]

The "moule intérieur" of Buffon is the aggregate of elementary parts which constitute the individual, and is thus the equivalent of Bonnet's germ,[5] as defined in the passage cited above. But Buffon further imagined that innumerable "molecules organiques" are dispersed throughout the world, and that alimentation consists in the appropriation by the parts of an organism of those molecules which are analogous to them. Growth, therefore, was, on this hypothesis, partly a process of simple evolution, and partly of what has been termed syngenesis. Buffon's opinion is, in fact, a sort of combination of views, essentially similar to those of Bonnet, with others, somewhat similar to those of the "Medici" whom Harvey condemns. The "molecules organiques" are physical equivalents of Leibnitz's "monads."

It is a striking example of the difficulty of getting people to use their own powers of investigation accurately, that this form of the doctrine of evolution should have held its ground so long; for it was thoroughly and completely exploded, not long after its enunciation, by Caspar Frederick Wolff, who in his *Theoria Generationis*, published in 1759, placed the opposite theory of epigenesis upon the secure foundation of fact, from which it has never been displaced. But Wolff had no immediate successors. The school of Cuvier was lamentably deficient in embryologists; and it was only in the course of the first thirty years of the present century, that Prévost and Dumas in France, and, later on, Döllinger, Pander, Von Bär, Rathke, and Remak in Germany, founded modern embryology; and, at the same time, proved the utter incompatibility of the hypothesis of evolution as formulated by Bonnet and Haller, with easily demonstrable facts.

Nevertheless, though the conceptions originally denoted by "evolution" and "development" were shown to be untenable, the words retained their application to the process by which the embryos of living beings gradually make their appearance; and the terms "Development," "Entwickelung," and "Evolutio" are now indiscriminately used for the series of genetic changes exhibited by living beings, by writers who would emphatically deny that "Development" or "Entwickelung" or "Evolutio," in the sense in which these words were usually employed by Bonnet or Haller, ever occurs.

Evolution, or development, is, in fact, at present employed in biology as a general name for the history of the steps by which any living being has acquired the morphological and the physiological characters which distinguish it. As civil history may be divided into biography, which is the history of individuals, and universal history, which is the history of the human race, so evolution falls naturally into two categories,—the evolution of the individual, and the evolution of the sum of living beings. It will be convenient to deal with the modern doctrine of evolution under these two heads.

1. *The Evolution of the Individual.*

No exception is, at this time, known to the general law, established upon an immense multitude of direct observations, that every living thing is evolved from a particle of matter in which no trace of the distinctive characters of the adult form of that living thing is discernible. This particle is termed a *germ*. Harvey[6] says—

> "Omnibus viventibus primordium insit, ex quo et a quo proveniant. Liceat hoc nobis *primordium vegetale* nominare; nempe substantiam quandam corpoream vitam habentem potentiâ; vel quoddam per se existens, quod aptum sit, in vegetativam formam, ab interno principio operante, mutari. Quale nempe primordium, ovum est et plantarum semen; tale etiam viviparorum conceptus et insectorum *vermis* ab Aristotele dictus: diversa scilicet diversorum viventium primordia."

The definition of a germ as "matter potentially alive, and having within itself the tendency to assume a definite living form," appears to meet all the requirements of modern science. For, notwithstanding it might be justly questioned whether a germ is not merely potentially, but rather actually, alive, though its vital manifestations are reduced to a minimum, the term "potential" may fairly be used in a sense broad enough to escape the objection. And the qualification of "potential" has the advantage of reminding us that the great characteristic of the germ is not so much what it is, but what it may, under suitable conditions, become. Harvey shared the belief of Aristotle—whose writings he so often quotes, and of whom he speaks as his precursor and model, with the generous respect with which one genuine worker should regard another—that such germs may arise by a process of "equivocal generation" out of not-living matter; and the aphorism so commonly ascribed to him, "*omne vivum ex ovo*," and which is indeed a fair summary of his reiterated assertions, though incessantly employed against the modern advocates of spontaneous generation, can be honestly so used only by those who have never read a score of pages of the *Exercitationes*. Harvey, in fact, believed as implicitly as Aristotle did in the equivocal generation of the lower animals. But, while the course of modern investigation has only brought out into greater prominence the accuracy of Harvey's conception of the nature and mode of development of germs, it has as distinctly tended to disprove the occurrence of equivocal generation, or abiogenesis, in the present course of nature. In the immense majority of both plants and animals, it is certain that the germ is not merely a body in which life is dormant or potential, but that it is itself simply a detached portion of the substance of a pre-existing living body; and the evidence has yet to be adduced which will satisfy any cautious reasoner that "omne vivum ex vivo" is not as well established a law of the existing course of nature as "omne vivum ex ovo."

In all instances which have yet been investigated, the

premier Monde, sorti immédiatement des MAINS du CREATEUR? . . . "Ne supposons que trois révolutions. La Terre vient de sortir des MAINS du CREATEUR. Des causes preparées par sa SAGESSE font développer de toutes parts les Germes. Les Etres organisés commencent à jouir de l'existence. Ils étoient probablement alors bien différens de ce qu'ils sont aujourd'hui. Ils l'etoient autant que se premier Monde différoit de celui que nous habitons. Nous manquons de moyens pour juger de ces dissemblances, et peut-être que le plus habile Naturaliste qui auroit été placé dans ce premier Monde y auroit entièrement méconnu nos Plantes et nos Animaux."

[1] "Ce mot (germe) ne désignera pas seulement un corps organisé *réduit en petit;* il désignera encore toute espèce de *préformation originelle dont un Tout originique peut résulter comme son principe immédiat.*"—*Palingénésie Philosophique*, part x. chap. ii.

[2] "M. Cuvier considérant que tous les êtres organisés sont dérivés de parens, et ne voyant dans la nature aucune force capable de produire l'organisation, croyait à la pré-éxistence des germes; non pas à la pré-existence d'un être tout formé, puisqu'il est bien évident que ce n'est que par des développemens successifs que l'être acquiert sa forme; mais, si l'on peut s'exprimer ainsi, à la pré-existence du *radical de l'être*, radical qui existe avant que la série des évolutions ne commence, et qui remonte certainement, suivant la belle observation de Bonnet, à plusieurs generations."—Laurillard, *Éloge de Cuvier*, note 12.

[6] *Exercitationes de Generatione*. Ex. 62, *Ovum esse primordium commune omnibus animalibus*.

substance of this germ has a peculiar chemical composition, consisting of at fewest four elementary bodies, viz., carbon, hydrogen, oxygen, and nitrogen, united into the ill-defined compound known as protein, and associated with much water, and very generally, if not always, with sulphur and phosphorus in minute proportions. Moreover, up to the present time, protein is known only as a product and constituent of living matter. Again, a true germ is either devoid of any structure discernible by optical means, or, at most, it is a simple nucleated cell.[1]

In all cases, the process of evolution consists in a succession of changes of the form, structure, and functions of the germ, by which it passes, step by step, from an extreme simplicity, or relative homogeneity, of visible structure, to a greater or less degree of complexity or heterogeneity; and the course of progressive differentiation is usually accompanied by growth, which is effected by intussusception. This intussusception, however, is a very different process from that imagined either by Buffon, or by Bonnet. The substance by the addition of which the germ is enlarged is, in no case, simply absorbed ready-made from the not-living world and packed between the elementary constituents of the germ, as Bonnet imagined; still less does it consist of the "molecules organiques" of Buffon. The new material is, in great measure, not only absorbed but assimilated, so that it becomes part and parcel of the molecular structure of the living body into which it enters. And, so far from the fully-developed organism being simply the germ *plus* the nutriment which it has absorbed, it is probable that the adult contains neither in form, nor in substance, more than an inappreciable fraction of the constituents of the germ, and that it is almost wholly made up of assimilated and metamorphosed nutriment. In the great majority of cases, at any rate, the full-grown organism becomes what it is by the absorption of not-living matter, and its conversion into living matter of a specific type. As Harvey says (Ex. 45), all parts of the body are nourished "ab eodem succo alibili, aliter aliterque cambiato," "ut plantæ omnes ex eodem communi nutrimento (sive rore seu terræ humore)."

In all animals and plants above the lowest, the germ is a nucleated cell, using that term in its broadest sense; and the first step in the process of the evolution of the individual is the division of this cell into two or more portions. The process of division is repeated, until the organism, from being unicellular, becomes multicellular. The single cell becomes a cell-aggregate; and it is to the growth and metamorphosis of the cells of the cell-aggregate thus produced, that all the organs and tissues of the adult owe their origin.

In certain animals belonging to every one of the chief groups into which the *Metazoa* are divisible, the cells of the cell-aggregate which results from the process of yelk division, and which is termed a *morula*, diverge from one another in such a manner as to give rise to a central space, around which they dispose themselves as a coat or envelope; and thus the morula becomes a vesicle filled with fluid, the *planula*. The wall of the planula is next pushed in on one side, or invaginated, whereby it is converted into a double-walled sac with an opening, the *blastospore*, which leads into the cavity lined by the inner wall. This cavity is the primitive alimentary cavity, or *archenterom;* the inner, or invaginated, layer is the *hypoblast*, the outer the *epiblast;* and the embryo, in this stage, is termed a *gastrula*. In all the higher animals, a layer of cells makes its appearance between the hypoblast and the epiblast, and is termed the *mesoblast*. In the further course of development, the epiblast becomes the ectoderm or epidermic layer of the body; the hypoblast becomes the epithelium of the middle portion of the alimentary canal; and the mesoblast gives rise to all the other tissues, except the central nervous system, which originates from an ingrowth of the epiblast.

With more or less modification in detail, the embryo has been observed to pass through these successive evolutional stages in sundry Sponges, Cœlenterates, Worms, Echinoderms, Tunicates, Arthropods, Mollusks, and Vertebrates; and there are valid reasons for the belief, that all animals of higher organization than the *Protozoa* agree in the general character of the early stages of their individual evolution. Each, starting from the condition of a simple nucleated cell, becomes a cell-aggregate; and this passes through a condition which represents the gastrula stage, before taking in the features distinctive of the group to which it belongs. Stated in this form, the "gastræa theory" of Haeckel appears to the present writer to be one of the most important and best founded of recent generalizations.

So far as individual plants and animals are concerned, therefore, evolution is not a speculation but a fact; and it takes place by epigenesis.

> "Animal . . . per *epigenesin* procreatur, materiam simul attrahit, parat, concoquit et eâdem utitur; formatur simul et augetur . . . primum futuri corporis concrementum . . . prout augeter, dividitur sensim et distinguitur in partes, non simul omnes, sed alias post alias natas, et ordine quasque suo emergentes."[2]

In these words, by the divination of genius, Harvey, in the 17th century, summed up the outcome of the work of all those who, with appliances he could not dream of, are continuing his labors in the 19th century.

Nevertheless, though the doctrine of epigenesis, as understood by Harvey, has definitively triumphed over the doctrine of evolution as understood by his opponents of the 18th century, it is not impossible that, when the analysis of the process of development is carried still further, and the origin of the molecular components of the physically gross, though sensibly minute, bodies which we term germs is traced, the theory of development will approach more nearly to metamorphosis than to epigenesis. Harvey thought that impregnation influenced the female organism as a contagion; and that the blood, which he conceived to be the first rudiment of the germ, arose in the clear fluid of the "colliquamentum" of the ovum by a process of concrescence, as a sort of living precipitate. We now know, on the contrary, that the female germ or ovum, in all the higher animals and plants, is a body which possesses the structure of a nucleated cell; that impregnation consists in the fusion of the substance[3] of another more or less modified nucleated cell, the male germ, with the ovum; and that the structural components of the body of the embryo are all derived, by a process of division, from the coalesced male and female germs. Hence it is conceivable, and indeed probable, that every part of the adult contains molecules derived both from the male and from the female parent; and that, regarded as a mass of molecules, the entire organism may be compared to a web of which the warp is derived from the female and the woof from the male. And each of these may constitute one individuality, in the same sense as the whole organism is one individual, although the matter of the organism has been constantly changing. The primitive male and female molecules may play the part of Buffon's "moules organiques," and mould the assimilated nutriment, each according to its own type, into innumerable new molecules. From this point of view, the process, which, in its superficial aspect, is epigenesis, appears, in essence, to be evolution, in the modified sense adopted in Bonnet's later writings; and development is merely the expansion of a potential organism or "original preformation" according to fixed laws.

2. *The Evolution of the Sum of Living Beings.*

The notion that all the kinds of animals and plants may have come into existence by the growth and modification of primordial germs is as old as speculative thought; but the modern scientific form of the doctrine can be traced historically to the influence of several converging lines of philosophical speculation and of physical observation, none of which go further back than the 17th century. These are:—

1. The enunciation by Descartes of the conception that the physical universe, whether living or not living, is a mechanism, and that, as such, it is explicable on physical principles.

2. The observation of the gradations of structure, from extreme simplicity to very great complexity, presented by living things, and of the relation of these graduated forms to one another.

3. The observation of the existence of an analogy between the series of gradations presented by the species which compose any great group of animals or plants, and the series

---

[1] In some cases of sexless multiplication the germ is a cell-aggregate—if we call germ only that which is already detached from the parent organism.

[2] Harvey, *Exercitationes de Generatione.* Ex. 45, *Quænam sit pulli materia et quomodo fiat in Ovo.*

[3] Not yet actually demonstrated in the case of the phænogamous plants.

of embryonic conditions of the highest members of that group.

4. The observation that large groups of species of widely different habits present the same fundamental plan of structure; and that parts of the same animal or plant, the functions of which are very different, likewise exhibit modifications of a common plan.

5. The observation of the existence of structures, in a rudimentary and apparently useless condition, in one species of a group, which are fully developed and have definite functions in other species of the same group.

6. The observation of the effects of varying conditions in modifying living organisms.

7. The observation of the facts of geographical distribution.

8. The observation of the facts of the geological succession of the forms of life.

1. Notwithstanding the elaborate disguise which fear of the powers that were led Descartes to throw over his real opinions, it is impossible to read the *Principes de la Philosophie* without acquiring the conviction that this great philosopher held that the physical world and all things in it, whether living or not living, have originated by a process of evolution, due to the continuous operation of purely physical causes, out of a primitive relatively formless matter.[1]

The following passage is especially instructive:—

> "Et tant s'en faut que je veuille que l'on croie toutes les choses que j'écrirai, que même je pretends en proposer ici quelques unes que je crois absolument être fausses; à savoir, je ne doute point que le monde n'ait été créé au commencement avec autant de perfection qu'il en a; en sorte que le soleil, la terre, la lune, et les étoiles ont été dès lors; et que la terre n'a pas eu seulement en soi les semences des plantes, mais que les plantes même en ont couvert une partie; et qu' Adam et Eve n'ont pas été créés enfans mais en âge d'hommes parfaits. La religion chrétienne veut que nous le croyons ainsi, et la raison naturelle nous persuade entièrement cette vérité; car si nous considérons la toute puissance de Dieu, nous devons juger que tout ce qu'il a fait a eu dès le commencement toute la perfection qu'il devoit avoir. Mais néanmoins, comme on connôitroit beaucoup mieux quelle a été la nature d'Adam et celle des arbres de Paradis si on avoit examiné comment les enfants se forment peu à peu dans le ventre de leurs mères et comment les plantes sortent de leurs semences, que si on avoit seulement considéré quels ils ont été quand Dieu les a créés: tout de même, nous ferons mieux entendre quelle est généralement la nature de toutes les choses qui sont au monde si nous pouvons imaginer quelques principes qui soient fort intelligibles et fort simples, desquels nous puissions voir clairement que les astres et la terre et enfin tout ce monde visible auroit pu être produit ainsi que de quelques semences (bien que nous sachions qu'il n'a pas été produit en cette façon) que si nous la decrivions seulement comme il est, ou bien comme nous croyons qu'il a été créé. Et parceque je pense avoir trouvé des principes qui sont tels, je tacherai ici de les expliquer."[2]

If we read between the lines of this singular exhibition of force of one kind and weakness of another, it is clear that Descartes believed that he had divined the mode in which the physical universe had been evolved; and the *Traité de l'homme* and the essay *Sur les Passions* afford abundant additional evidence that he sought for, and thought he had found, an explanation of the phenomena of physical life by deduction from purely physical laws.

Spinoza abounds in the same sense, and is as usual perfectly candid—

> "Naturæ leges et regulæ, secundum quas omnia fiunt et ex unis formis in alias mutantur, sunt ubique et semper eadem."[3]

Leibnitz's doctrine of continuity necessarily led him in the same direction; and, of the infinite multitude of monads with which he peopled the world, each is supposed to be the focus of an endless process of evolution and involution. In the *Protogæa*, xxvi., Leibnitz distinctly suggests the mutability of species—

> "Alii mirantur in saxis passim species videri quas vel in orbe cognito, vel saltem in vicinis locis frustra quæras. Ita *Cornua Ammonis*, quæ ex nautilorum numero habeantur, passim et forma et magnitudine (nam et pedali diametro aliquando repe iuntur) ab omnibus illis naturis discrepare dicunt, quas præbet mare. Sed quis absconditos ejus recessus aut subterraneas abyssos pervestigavit? quam multa nobis animalia antea ignota offert novus orbis? Et credibile est per magnas illas conversiones etiam animalium species plurimum immutatas."

Thus in the end of the 17th century the seed was sown which has at intervals brought forth recurrent crops of evolutional hypotheses, based, more or less completely, on general reasonings.

Among the earliest of these speculations is that put forward by Benoit de Maillet in his *Telliamed*, which, though printed in 1735, was not published until twenty-three years later. Considering that this book was written before the time of Haller, or Bonnet, or Linnæus, or Hutton, it surely deserves more respectful consideration than it usually receives. For De Maillet not only has a definite conception of the plasticity of living things, and of the production of existing species by the modification of their predecessors; but he clearly apprehends the cardinal maxim of modern geological science, that the explanation of the structure of the globe is to be sought in the deductive application to geological phenomena of the principles established inductively by the study of the present course of nature. Somewhat later, Maupertuis[4] suggested a curious hypothesis as to the causes of variation, which he thinks may be sufficient to account for the origin of all animals from a single pair. Robinet[5] followed out much the same line of thought as De Maillet, but less soberly; and Bonnet's speculations in the *Palingénésie*, which appeared in 1769, have already been mentioned. Buffon (1753–1778), at first a partisan of the absolute immutability of species, subsequently appears to have believed that larger or smaller groups of species have been produced by the modification of a primitive stock; but he contributed nothing to the general doctrine of evolution.

Erasmus Darwin (*Zoonomia*, 1794), though a zealous evolutionist, can hardly be said to have made any real advance on his predecessors; and, notwithstanding that Goethe (1791–4) had the advantage of a wide knowledge of morphological facts, and a true insight into their signification, while he threw all the power of a great poet into the expression of his conceptions, it may be questioned whether he supplied the doctrine of evolution with a firmer scientific basis than it already possessed. Moreover, whatever the value of Goethe's labors in that field, they were not published before 1820, long after evolutionism had taken a new departure from the works of Treviranus and Lamarck—the first of its advocates who were equipped for their task with the needful large and accurate knowledge of the phenomena of life, as a whole. It is remarkable that each of these writers seems to have been led, independently and contemporaneously, to invent the same name of "Biology" for the science of the phenomena of life; and thus, following Buffon, to have recognized the essential unity of these phenomena, and their contradistinction from those of inanimate nature. And it is hard to say whether Lamarck or Treviranus has the priority in propounding the main thesis of the doctrine of evolution; for though the first volume of Treviranus's *Biologie* appeared only in 1802, he says, in the preface to his later work, the *Erscheinungen und Gesetze des organischen Lebens*, dated 1831, that he wrote the first volume of the *Biologie* "nearly five-and-thirty years ago," or about 1796.

Now, in 1794, there is evidence that Lamarck held doctrines which present a striking contrast to those which are to be found in the *Philosophie Zoologique*, as the following passages show:—

> 685. Quoique mon unique objet dans cet article n'ait été que de traiter de la cause physique de l'entretien de la vie des êtres organiques malgré cela j'ai osé avancer en débutant, que l'existence de ces êtres étonnants n'apartiennent nullement à la nature; que tout ce qu'on peut entendre par le mot *nature*, ne pouvoit donner la vie, c'est-à-dire, que toutes les qualités de la matiére, jointes à toutes les circonstances possibles, et même à l'activité répandue dans l'univers, ne pouvaient point produire un être muni du mouvement organique, capable de reproduir son semblable, et sujet à la mort.
>
> 686. Tous les individus de cette nature, qui existent, proviennent d'individus semblables qui tous ensemble constituent l'espèce entière. Or, je crois qu'il est aussi impossible à l'homme de connôitre la cause physique du premier individu de chaque espèce, que d'assigner aussi physiquement la cause

> de l'existence de la matière ou de l'univers entier. C'est au moins ce que le résultat de mes connaissances et de mes réflexions me portent à penser. S'il existe beaucoup de variétés produites par l'effet des circonstances, ces variétés ne dénaturent point les espèces; mais on se trompe, sans doute souvent, en indiquant comme espèce, ce qui n'est que variété; et alors je sens que cette erreur peut tirer à conséquence dans les raisonnements que l'on fait sur cette matière.[1]

The first three volumes of Treviranus's *Biologie*, which contains his general views of evolution, appeared between 1802 and 1805. The *Recherches sur l'organisation des corps vivants*, which sketches out Lamarck's doctrines, was published in 1802; but the full development of his views, in the *Philosophie Zoologique*, did not take place until 1809.

The *Biologie* and the *Philosophie Zoologique* are both very remarkable productions, and are still worthy of attentive study, but they fell upon evil times. The vast authority of Cuvier was employed in support of the traditionally respectable hypotheses of special creation and of catastrophism; and the wild speculations of the *Discours sur les Révolutions de la Surface du Globe* were held to be models of sound scientific thinking, while the really much more sober and philosophical hypotheses of the *Hydrogeologie* were scouted. For many years it was the fashion to speak of Lamarck with ridicule, while Treviranus was altogether ignored.

Nevertheless, the work had been done. The conception of evolution was henceforward irrepressible, and it incessantly reappears, in one shape or another,[2] up to the year 1858, when Mr. Darwin and Mr. Wallace published their *Theory of Natural Selection*. The *Origin of Species* appeared in 1859; and it is within the knowledge of all whose memories go back to that time, that, henceforward, the doctrine of evolution has assumed a position and acquired an importance which it never before possessed. In the *Origin of Species*, and in his other numerous and important contributions to the solution of the problem of biological evolution, Mr. Darwin confines himself to the discussion of the causes which have brought about the present condition of living matter, assuming such matter to have once come into existence. On the other hand, Mr. Spencer[3] and Professor Haeckel[4] have dealt with the whole problem of evolution. The profound and vigorous writings of Mr. Spencer embody the spirit of Descartes in the knowledge of our own day, and may be regarded as the "Principes des Philosophie" of the 19th century; while, whatever hesitation may not unfrequently be felt by less daring minds, in following Haeckel in many of his speculations, his attempt to systematize the doctrine of evolution and to exhibit its influence as the central thought of modern biology, cannot fail to have a far-reaching influence on the progress of science.

If we seek for the reason of the difference between the scientific position of the doctrine of evolution a century ago, and that which it occupies now, we shall find it in the great accumulation of facts, the several classes of which have been enumerated above, under the second to the eighth heads. For those which are grouped under the second to the seventh of these classes, respectively, have a clear significance on the hypothesis of evolution, while they are unintelligible if that hypothesis be denied. And those of the eighth group are not only unintelligible without the assumption of evolution, but can be proved never to be discordant with that hypothesis, while, in some cases, they are exactly such as the hypothesis requires. The demonstration of these assertions would require a volume, but the general nature of the evidence on which they rest may be briefly indicated.

2. The accurate investigation of the lowest forms of animal life, commenced by Leeuwenhoek and Swammerdam, and continued by the remarkable labors of Reaumur, Trembley, Bonnet, and a host of other observers in the latter part of the 17th and the first half of the 18th centuries, drew the attention of biologists to the gradation in the complexity of organization which is presented by living beings, and culminated in the doctrine of the "échelle des êtres," so powerfully and clearly stated by Bonnet; and, before him, adumbrated by Locke and by Leibnitz. In the then state of knowledge, it appeared that all the species of animals and plants could be arranged in one series; in such a manner that, by insensible gradations, the mineral passed into the plant, the plant into the polype, the polype into the worm, and so, through gradually higher forms of life, to man, at the summit of the animated world.

But, as knowledge advanced, this conception ceased to be tenable in the crude form in which it was first put forward. Taking into account existing animals and plants alone, it became obvious that they fell into groups which were more or less sharply separated from one another; and, moreover, that even the species of a genus can hardly ever be arranged in linear series. Their natural resemblances and differences are only to be expressed by disposing them as if they were branches springing from a common hypothetical centre.

Lamarck, while affirming the verbal proposition that animals form a single series, was forced by his vast acquaintance with the details of zoology to limit the assertion to such a series as may be formed out of the abstractions constituted by the common characters of each group.[5]

Cuvier on anatomical, and Von Baer on embryological grounds, made the further step of proving that, even in this limited sense, animals cannot be arranged in a single series, but that there are several distinct plans of organization to be observed among them, no one of which, in its highest and most complicated modification, leads to any of the others.

The conclusions enunciated by Cuvier and Von Baer have been confirmed in principle by all subsequent research into the structure of animals and plants. But the effect of the adoption of these conclusions has been rather to substitute a new metaphor for that of Bonnet than to abolish the conception expressed by it. Instead of regarding living things as capable of arrangement in one series like the steps of a ladder, the results of modern investigation compel us to dispose them as if they were the twigs and branches of a tree. The ends of the twigs represent individuals, the smallest groups of twigs species, larger groups genera, and so on, until we arrive at the source of all these ramifications of the main branch, which is represented by a common plan of structure. At the present moment, it is impossible to draw up any definition, based on broad anatomical or developmental characters, by which any one of Cuvier's great groups shall be separated from all the rest. On the contrary, the lower members of each tend to converge towards the lower members of all the others. The same may be said of the vegetable world. The apparently clear distinction between flowering and flowerless plants has been broken down by the series of gradations between the two exhibited by the *Lycopodiaceæ*, *Rhizocarpeæ*, and *Gymnospermeæ*. The groups of *Fungi*, *Licheneæ*, and *Algæ* have completely run into one another, and, when the lowest forms of each are alone considered, even the animal and vegetable kingdoms cease to have a definite frontier.

If it is permissible to speak of the relations of living forms to one another metaphorically, the similitude chosen must undoubtedly be that of a common root, whence two main trunks, one representing the vegetable and one the animal world, spring; and, each dividing into a few main branches, these subdivide into multitudes of branchlets and these into smaller groups of twigs.

As Lamarck has well said:[6]—

> Il n'y a que ceux qui se sont longtemps et fortement occupés de la détermination des espèces, et qui ont consulté de riches collections, qui peuvent savior jusqua'à quel point les *espèces*, parmi les corps vivants se fondent les unes dans les autres, et qui ont pu se convaincre que, dans les parties où nous voyons des *espèces* isolés, cela n'est ainsi que parcequ'il nous en manque d'autres qui en sont plus voisines et que nous n'avons pas encore recueillies.
>
> Je ne veux pas dire pour cela que les animaux qui existent forment une série très-simple et partout également nuancée; mais je dis qu'ils forment une série rameuse, irréguliérement

---

[1] *Recherches sur les causes des principaux faits physiques*, par J. B. Lamarck. Paris. Seconde année de la République. In the preface, Lamarck says that the work was written in 1776, and presented to the Academy in 1780; but it was not published before 1794, and at that time it presumably expressed Lamarck's mature views. It would be interesting to know what brought about the change of opinion manifested in the *Recherches sur l'organisation des corps vivants*, published only seven years later.

[5] "Il s'agit donc de prover que la série qui constitute l'échelle animale réside essentiellement dans la distribution des masses principales qui la composent et non dans celle des espèces ni même toujours dans celle des genres."—*Phil. Zoologique*, chap. v.

[6] *Philosophie Zoologique*, première partie, chap. iii.

graduée et qui n'a point de discontinuité dans ses parties, ou qui, du moins, n'en a toujours pas eu, s'il est vrai que, par suite de quelques espèces perdues, il s'en trouve quelque part. Il en resulte que les *espèces* qui terminent chaque rameau de la série générale tiennent, au moins d'un côté, à d'autres espèces voisines qui se nuancent avec elles. Voilà ce que l'état bien connu des choses me met maintenant à portée de demontrer. Je n'ai besoin d'aucune hypothèse ni d'aucune supposition pour cela : j'en a teste toutes naturalistes observateurs.

3. In a remarkable essay[1] Meckel remarks—

> "There is no good physiologist who has not been struck by the observation that the original form of all organisms is one and the same, and that out of this one form, all, the lowest as well as the highest, are developed in such a manner that the latter pass through the permanent forms of the former as transitory stages. Aristotle, Haller, Harvey, Kielmeyer, Autenrieth, and many others have either made this observation incidentally, or, especially the latter, have drawn particular attention to it and drawn therefrom results of permanent importance for physiology."

Meckel proceeds to exemplify the thesis, that the lower forms of animals represent stages in the course of the development of the higher, with a large series of illustrations. After comparing the Salamanders and the perennibranchiate *Urodela* with the Tadpoles and the Frogs, and enunciating the law that the more highly any animal is organized the more quickly does it pass through the lower stages, Meckel goes on to say—

> "From these lowest Vertebrata to the highest, and to the highest forms among these, the comparison between the embryonic conditions of the higher animals and the adult states of the lower can be more completely and thoroughly instituted than if the survey is extended to the Invertebrata, inasmuch as the latter are in many respects constructed upon an altogether too dissimilar type; indeed they often differ from one another far more than the lowest vertebrate does from the highest mammal; yet the following pages will show that the comparison may be also extended to them with interest. In fact, there is a period when, as Aristotle long ago said, the embryo of the highest animal has the form of a mere worm, and devoid of internal and external organization, is merely an almost structureless lump of polype-substance. Notwithstanding the origin of organs, it still for a certain time, by reason of its want of an internal bony skeleton, remains worm and mollusk, and only later enters into the series of the Vertebrata, although traces of the vertebral column even in the earliest periods testify its claim to a place in that series."—*Op. cit.* pp. 4, 5.

If Meckel's proposition is so far qualified, that the comparison of adult with embryonic forms is restricted within the limits of one type of organization; and, if it is further recollected, that the resemblance between the permanent lower form and the embryonic stage of a higher form is not special but general, it is in entire accordance with modern embryology; although there is no branch of biology which has grown so largely, and improved its methods so much since Meckel's time, as this. In its original form, the doctrine of "arrest of development," as advocated by Geoffrey St. Hilaire and Serres, was no doubt an over-statement of the case. It is not true, for example, that a fish is a reptile arrested in its development, or that a reptile was ever a fish; but it is true that the reptile embryo, at one stage of its development, is an organism which, if it had an independent existence, must be classified among fishes; and all the organs of the reptile pass, in the course of their development, through conditions which are closely analogous to those which are permanent in some fishes.

4. That branch of biology which is termed Morphology is a commentary upon, and expansion of, the proposition that widely different animals or plants, and widely different parts of animals or plants, are constructed upon the same plan. From the rough comparison of the skeleton of a bird with that of a man by Belon, in the sixteenth century (to go no further back), down to the theory of the limbs and the theory of the skull at the present day; or, from the first demonstration of the homologies of the parts of a flower by C. F. Wolff, to the present elaborate analysis of the floral organs, morphology exhibits a continual advance towards the demonstration of a fundamental unity among the seeming diversities of living structures. And this demonstration has been completed by the final establishment of the cell theory, which involves the admission of a primitive conformity, not only of all the elementary structures in animals and plants respectively, but of those in the one of these great divisions of living things with those in the other. No *a priori* difficulty can be said to stand in the way of evolution, when it can be shown that all animals and all plants proceed by modes of development, which are similar in principle, from a fundamental protoplasmic material.

5. The innumerable cases of structures, which are rudimentary and apparently useless, in species, the close allies of which possess well developed and functionally important homologous structures, are readily intelligible on the theory of evolution, while it is hard to conceive their *raison d'être* on any other hypothesis. However, a cautious reasoner will probably rather explain such cases deductively from the doctrine of evolution than endeavor to support the doctrine of evolution by them. For it is almost impossible to prove that any structure, however rudimentary, is useless—that is to say, that it plays no part whatever in the economy; and, if it is in the slightest degree useful, there is no reason why, on the hypothesis of direct creation, it should not have been created. Nevertheless, double-edged as is the argument from rudimentary organs, there is probably none which has produced a greater effect in promoting the general acceptance of the theory of evolution.

6. The older advocates of evolution sought for the causes of the process exclusively in the influence of varying conditions, such as climate and station, or hybridization, upon living forms. Even Treviranus has got no further than this point. Lamarck introduced the conception of the action of an animal on itself as a factor in producing modification. Starting from the well-known fact that the habitual use of a limb tends to develop the muscles of the limb, and to produce a greater and greater facility in using it, he made the general assumption that the effort of an animal to exert an organ in a given direction tends to develop the organ in that direction. But a little consideration showed that, though Lamarck had seized what, as far as it goes, is a true cause of modification, it is a cause the actual effects of which are wholly inadequate to account for any considerable modification in animals, and which can have no influence at all in the vegetable world; and probably nothing contributed so much to discredit evolution, in the early part of this century, as the floods of easy ridicule which were poured upon this part of Lamarck's speculation. The theory of natural selection, or survival of the fittest, was suggested by Wells in 1813, and further elaborated by Matthew in 1831. But the pregnant suggestions of these writers remained practically unnoticed and forgotten, until the theory was independently devised and promulgated by Darwin and Wallace in 1858, and the effect of its publication was immediate and profound.

Those who were unwilling to accept evolution, without better grounds than such as are offered by Lamarck or the author of that particularly unsatisfactory book, the *Vestiges of the Natural History of the Creation*, and who therefore preferred to suspend their judgment on the question, found in the principle of selective breeding, pursued in all its applications with marvellous knowledge and skill by Mr. Darwin, a valid explanation of the occurrence of varieties and races; and they saw clearly that, if the explanation would apply to species, it would not only solve the problem of their evolution, but that it would account for the facts of teleology, as well as for those of morphology; and for the persistence of some forms of life unchanged through long epochs of time, while others undergo comparatively rapid metamorphosis.

How far "natural selection" suffices for the production of species remains to be seen. Few can doubt that, if not the whole cause, it is a very important factor in that operation; and that it must play a great part in the sorting out of varieties into those which are transitory and those which are permanent.

But the causes and conditions of variation have yet to be thoroughly explored; and the importance of natural selection will not be impaired, even if further inquiries should prove that variability is definite, and is determined in certain directions rather than in others, by conditions inherent in that which varies. It is quite conceivable that every species tends to produce varieties of a limited number and kind, and that the effect of natural selection is to favor the development of some of these, while it opposes the development of others along their predetermined lines of modification.

---

[1] "Entwurf einer Darstellung der zwischen dem Embryozustände der höheren Thiere und dem permanenten der niederen stattfindenden Parallele," *Beiträge zur Vergleichenden Anatomie*, Bd. ii. 1811.

7. No truths brought to light by biological investigation were better calculated to inspire distrust of the dogmas intruded upon science in the name of theology, than those which relate to the distribution of animals and plants on the surface of the earth. Very skilful accommodation was needful, if the limitation of sloths to South America, and of the ornithorhynchus to Australia, was to be reconciled with the literal interpretation of the history of the deluge; and, with the establishment of the existence of distinct provinces of distribution, any serious belief in the peopling of the world by migration from Mount Ararat came to an end.

Under these circumstances, only one alternative was left for those who denied the occurrence of evolution; namely, the supposition that the characteristic animals and plants of each great province were created, as such, within the limits in which we find them. And as the hypothesis of "specific centres," thus formulated, was heterodox from the theological point of view, and unintelligible under its scientific aspect, it may be passed over without further notice, as a phase of transition from the creational to the evolutional hypothesis.

8. In fact, the strongest and most conclusive arguments in favor of evolution are those which are based upon the facts of geographical, taken in conjunction with those of geological, distribution.

Both Mr. Darwin and Mr. Wallace lay great stress on the close relation which obtains between the existing fauna of any region and that of the immediately antecedent geological epoch in the same region; and rightly, for it is in truth inconceivable that there should be no genetic connection between the two. It is possible to put into words the proposition, that all the animals and plants of each geological epoch were annihilated, and that a new set of very similar forms was created for the next epoch, but it may be doubted if any one who ever tried to form a distinct mental image of this process of spontaneous generation on the grandest scale, ever really succeeded in realizing it.

Within the last twenty years, the attention of the best palæontologists has beeen withdrawn from the hodman's work of making "new species" of fossils, to the scientific task of completing our knowledge of individual species, and tracing out the succession of the forms presented by any given type in time.

Those who desire to inform themselves of the nature and extent of the evidence bearing on these questions may consult the works of Rütimeyer, Gaudry, Kowalewsky, Marsh, and the writer of the present article. It must suffice, in this place, to say that the successive forms of the Equine type have been fully worked out; while those of nearly all the other existing types of Ungulate mammals and of the *Carnivora* have been nearly as closely followed through the Tertiary deposits; the gradations between birds and reptiles have been traced; and the modifications undergone by the *Crocodilia*, from the Triassic epoch to the present day, have been demonstrated. On the evidence of palæontology, the evolution of many existing forms of animal life from their predecessors is no longer an hypothesis, but an historical fact; it is only the nature of the physiological factors to which that evolution is due which is still open to discussion. (T. H. H.)

II. EVOLUTION IN PHILOSOPHY.

Definition.—The modern biological doctrine of evolution, which regards the higher forms of life as gradually arising out of the lower, owes its chief philosophic significance to the fact that it renders definite and precise one part of a general theory of the world viewed as an orderly succession of events or as a process of becoming. This theory is put forward as an answer to one of the two problems of philosophy conceived as an interpretation of real existence. The first of these problems concerns itself with what may be called the statical aspect of the world, and inquires into the ultimate nature of all reality (matter and mind), viewed as coexistent and apart from time. The second problem treats of the dynamical aspect of the world, and has to do with the process by which the totality of things has come to be what it is, and is still being transformed. It is this latter problem which the various theories of evolution seek to solve.

The most general meaning of evolution may be defined as follows: Evolution includes all theories respecting the origin and order of the world which regard the higher or more complex forms of existence as following and depending on the lower and simple forms, which represent the course of the world as a gradual transition from the indeterminate to the determinate, from the uniform to the varied, and which assume the cause of this process to be immanent in the world itself that is thus transformed. All theories of evolution, properly so called, regard the physical world as a gradual progress from the simple to the complex, look upon the development of organic life as conditioned by that of the inorganic world, and view the course of mental life both of the individual and of the race as correlated with a material process. This definition covers roughly the principal historical systems bearing the name of evolution, as well as others which have hardly as yet been characterized by this title.

It is clear by this definition that we cannot now press the etymological force of the word. Evolution has no doubt often been conceived as an unfolding of something already contained in the original, and this view is still commonly applied to organic evolution both of the individual and of the species. It will be found that certain metaphysical systems of evolution imply this idea of an unfolding of something existing in germ or at least potentially in the antecedent. On the other hand, the modern doctrine of evolution, with its ideas of elements which combine, and of causation as transformation of energy, does not necessarily imply this notion. It may be remarked that some of the arguments brought against the modern doctrine rest on the fallacious assumption that the word is still used in its etymological sense, and that consequently that which evolves must contain in some shape what is evolved (*e.g.*, inorganic matter must contain life and consciousness).

Evolution is thus almost synonymous with progress, though the latter term is usually confined to processes of development in the moral as distinguished from the physical world. Further, this idea, as Mr. Spencer remarks, has rather a subjective than an objective source, since it points to an increased *value* in existence as judged by our feelings. At the same time, inasmuch as conscious and more particularly human life is looked on by the evolutionist as the highest phase of all development, and since man's development is said to be an increase in well-being and happiness, we do not greatly err when we speak of evolution as a transition from the lower to the higher, from the worse to the better. Another respect in which the whole process of evolution may be said to be a progress is in its relation to our perceptions as æsthetic spectators, the higher phases of the process being the more varied, the fuller, and the more perfect. Apart from these subjective estimates, evolution is first of all as a whole a progress from the lower to the higher, in the sense that it is a substitution of a complex for a simple type of existence; and it is such a progress, secondly, in the narrow sense of organic development if not in the wider sense of cosmic development, inasmuch as all advance implies a larger measure of adaptation and so of permanence.

Problems solved by Evolution.—The hypothesis of evolution aims at answering a number of questions respecting the becoming or genesis of things. Of these the first is the problem of explaining change, that is to say, of accounting for that incessant process of transformation which the world manifests. The form which this question has commonly taken is, "What is motion, and how does it arise?" The second inquiry relates to the factor of intelligible order in the world, to the existence of general classes of things, including minds, of universal laws, and finally to that appearance of a rational end towards which things tend. Thirdly, it is necessary to account for the origin of organic beings, which appear to be subordinated to different principles from those which control inorganic bodies. Lastly, we have the apparent mystery of a genesis of conscious minds in dependence on physical bodies. These are the principal inquiries which the various theories of evolution aim more or less completely at answering. As a subordinate question we may mention the meaning of human history, and its relation to physical processes.

Evolution, Creation, and Emanation.—In seeking to answer these questions, the hypothesis of an evolution of the cosmos with all that it contains competes, in part at least, with two other principal doctrines respecting the origin of the world. These are the theory of direct creation by a personal Deity and that of emanation.

It is clear that the doctrine of evolution is directly antagonistic to that of creation. Just as the biological doctrine of the transmutation of species is opposed to that of special creations, so the idea of evolution as applied to the formation of the world as a whole, is opposed to that of a direct creative volition. It substitutes within the ground which it covers the idea of a natural and necessary process for that of an arbitrary volitional process.

The theory of a personal Creator answers the questions enumerated above by referring the form of the world to an act of direct creation. As an extreme doctrine, it views matter as well as form as the product of divine volition; in a modified form, it conceives the Deity as simply fashioning the uncreated material of the world; and in a still more restricted form, it regards the universal laws or forms which are impressed on things as co-eternal with the Deity. Advancing knowledge has gradually limited the sphere of direct creative activity, by referring the present order of the world to the action of secondary causes. Hence this theory only now competes with the hypothesis of evolution at one or two points, more especially the production of living forms, the origin of the human mind, and the nature of history,—which last is conceived as somehow controlled by divine action in the shape of Providence. The question how far the doctrine of evolution, in its most extended and elaborate form, absolutely excludes the idea of creative activity need not be dwelt on here. It is sufficient to say that the theory of evolution, by assuming an intelligible and adequate principle of change, simply eliminates the notion of creation from those regions of existence to which it is applied.

The doctrine of emanation, which had its origin in the East, and was developed by the Neoplatonists, Gnostics, and Cabalists, is a philosophic transformation of the idea of an original creation of the world. It regards the world as a product of the divine nature, and so far it is a theory of creation. On the other hand, it conceives of this production as necessary, and analogous rather to a physical than to a moral action. In this respect it agrees with the doctrine of evolution. It further coincides with this doctrine in the recognition of a scale of existence. It differs from this last inasmuch as it reverses the order of evolution, by making the original stage the most perfect and all later stages a succession of degradations. In one respect, the theory of emanation has a curious relation to that of evolution. As we have seen, the process of evolution is from the indeterminate to the determinate. This is often expressed as a progress from the universal to the particular. Thus the primordial matter assumed by the early Greek physicists may be said to be the universal substance out of which particular things arise. The doctrine of emanation again regards the world as a process of particularization. Yet the resemblance here is more apparent than real. The universal is, as Mr. Spencer remarks, a subjective idea; and the general forms, existing *ante res*, which play so prominent a part in Greek and mediæval philosophy, do not in the least correspond to the homogeneous matter of the physical evolutionists. The one process is a logical operation, the other a physical. The theory of emanation, which had its source in certain moral and religious ideas, aims first of all at explaining the origin of mental or spiritual existence as an effluence from the divine and absolute spirit. In the next place, it seeks to account for the general laws of the world, for the universal forms of existence, as ideas which emanate from the Deity. By some it was developed into a complete philosophy of the world, in which matter itself is viewed as the lowest emanation from the absolute. In this form it stands in sharp antithesis to the doctrine of evolution, both because the former views the world of particular things and events as essentially unreal and illusory; and because the latter, so far as it goes, looks on matter as eternal, and seeks to explain the general forms of things as we perceive them by help of simpler assumptions. In certain theories known as doctrines of emanation, only mental existence is referred to the absolute source, while matter is viewed as eternal and distinct from the divine nature. In this form the doctrine of emanation approaches, as we shall see, certain forms of the evolution theory.

Forms of Doctrine of Evolution.—Let us now see how the doctrine of evolution deals with the problems of becoming as above defined. And here it becomes necessary to distinguish between different ways of formulating and interpreting the idea of evolution. The various modes of conceiving and interpreting the idea of a natural evolution of things depend on the answers given to three principal questions respecting the nature and causes of the process. These are:—I. How far is the process a real objective one? II. What is the nature of that reality which makes the content, so to speak, of the process of evolution? and III. How is the process effected?

I. First of all, very different views may be taken of the reality of the process of becoming, generation, and transformation. On the one side we have the extreme view of the Eleatics, that there is no such thing as change or individual object, that real being is one and unchangeable, and that what appears like the formation and destruction of things is an illusion of the senses. At the other extreme we have the view that all reality consists in the process of becoming, or self-realization, and that nothing persists save this law of evolution itself. Between these two extremes there lie a number of intermediate conceptions, as that of a varying and progressive activity, of a persistent force, or of a gradual manifestation of an unchanging substance. The reality of the process is viewed in a peculiar light from the standpoint of modern Subjective Idealism, which regards time as nothing but a mental form. It is to be added that the process of cosmic evolution may present different degrees of reality. Thus to the ancient atomists the real part of the process is the combination of atoms. There is no absolute generation or destruction of things. Further, the evolution of the world of sensible qualities (color, etc.) of things, is illusory, and has only a subjective existence in our sensations. The modern scientific doctrine of evolution carries out this view of its reality, both by its conception of the material world as objectively rēal only in its forces and movements, and by its doctrine of the conservation of energy, which teaches that amid all change and transformation there is something (though not necessarily a metaphysical thing) which persists.

II. Secondly, the view of evolution will vary according to the conception of that substance or real thing which enters into the process and constitutes its essential content. We have said that the problems of being and becoming (*esse* and *fieri*) are distinct, yet they cannot be discussed in perfect isolation. More particularly our idea of becoming must be determined by our notion of that existing reality which underlies the process.

It follows from our definition of evolution that its main problem is to conceive of material and mental development in their mutual relation. There are various ways of effecting this result. First of all, the material and the mental may be regarded from a dualistic point of view as perfectly distinct kinds of reality. According to this view, physical evolution as taking place in the inorganic world, and mental evolution as unfolded in man's history, are two unconnected processes. Further, the fact of their correlation in organic development must either be left unexplained altogether, or can only be referred to the arbitrary action of some supernatural power.

Opposed to this dualistic conception of reality there are the monistic conceptions, which conceive of all parts of the process of evolution as homogeneous and identical. Of these the first is the materialistic, which assumes but one substance, and regards mind as but a property or particular manifestation of matter. On this view, mental evolution is simply one phase of material, and the whole course of cosmic evolution may be described as a production of mind out of matter.

The next monistic conception is the spiritualistic, which assumes but one substance—mind, and resolves the reality of the material world into a spiritual principle.[1] According to this way of looking at the world-process, material and mental evolution are but two continuous phases of one spiritual movement. From the operation of inanimate nature up to human history it is the same spiritual reality which manifests itself.

Finally, there is the monistic conception in the narrow modern sense, viz., that which views the material and the mental as two sides of one and the same reality. According to this view, physical evolution as manifested in the material world, and mental evolution as seen in human life, may each be regarded as a two-sided process. The first is simply that part of the process in which the material side is most conspicuous; the second, that in which the mental side is so. This monistic conception shows itself in a number of forms,—from the crude semi-mythological conception of a cosmic organism or world-animal, which is at once body and soul, up to the metaphysical doctrine of one substance with two attributes.

---

[1] Of course, there is a transition from the dualistic theory to the spiritualistic in those doctrines which allow a certain reality to matter, but only as something dead or existing potentially.

III. In the third place, the form of the doctrine of evolution will vary according to the conception of the force or activity which effects the process. This point, though closely related to the last, is not identical with it. It is one thing to understand *what* it is that evolves itself, another thing to comprehend *how* the process is brought about. The latter point is of even greater importance for studying the various theories of evolution than the former.

There are two strongly contrasted modes of viewing all action or change. The first is drawn from the region of physical events, and views the change as conditioned by antecedents or efficient causes. This way of looking at change gives the mechanical view of evolution. The second is drawn from the region of our conscious volitions regarded as themselves undetermined by antecedent causes, and conceives of change as related to and determined by some end or purpose. This gives the teleological view of evolution. Although there is a natural affinity between the mechanical and the materialistic conception of evolution on the one side, and between the teleological and the spiritualistic on the other, they are not exactly co-extensive. The teleological view does no doubt imply the acceptance of a spiritual or quasi-spiritual principle; it refers the form and order of the world to the action of an intelligence (conscious or unconscious) which combines particular events as means to some comprehensive end. The mechanical view, on the other hand, does not necessarily imply the acceptance of a material principle as the one reality. It is applicable to mind as well as to body. Thus, on the determinist theory, mental development is as much a mechanical process as physical development.

Adopting this distinction between the mechanical and teleological conception of evolution as the essential one, we may roughly classify the various systems of evolution under the three heads:—(*a*), those in which the mechanical view predominates; (*b*), those in which the teleological view predominates; and (*c*), those in which the two views are combined in some larger conception.

(*a*) The mechanical interpretation may first of all be combined with a dualistic theory. Such would be Descartes's doctrine of evolution if it had been fully worked out on its mental side. It has been observed, however, that the mechanical view is naturally allied to the materialistic theory. Systems of evolution which arise out of this combination seek to resolve all appearance of order and purpose in the physical world into the combined effect of elementary forces or actions. They adopt a mechanical conception of organic bodies and their processes. Finally, they regard mental life and its evolution as a process of combination exactly analogous to that of physical evolution and closely correlated with a certain mode of this process. In this way they lead to a materialistic conception of man's origin and development as conditioned by physical circumstance and organic changes.

This thorough-going materialistic way of viewing the origin and formation of the world finds its greatest obstacle in the genesis of conscious life. Hence it has from the earliest been modified in one in one or two ways so as to provide a primordial source of sensation and thought, without, however, abandoning a strictly mechanical view of the process. The first and crude form in which this modification presents itself is that of an original, thin, quasi-material substance (as ether), which may serve as the raw material, so to speak, of individual minds. The formation of these minds, however, is regarded as a strictly mechanical process, and related to that of physical evolution in the narrow sense. This theory of the origin of mental existence clearly approaches one of the forms of the doctrine of emanation already referred to. We have only to conceive of the primordial mental substance as the infinite being, transcending our finite world, and the doctrine becomes one of emanation. The second modification of this view consists in the theory that all parts of matter are endowed with sensibility, but that the sensations are not themselves (as teleological factors) the productive force in the process, but are rather the appendages of the real factors. The world forms itself according to strictly mechanical laws of combination, and the evolution of the various grades of mind in the organic region takes place by a composition of elementary feelings exactly similar to the process of material combination.

Before leaving the systems which are based on the mechanical view, a bare allusion must be made to a recent suggestion that all things consist ultimately of mental substance ("mind-stuff"), which combines itself both in the material world and in the region of conscious mind according to strictly mechanical principles.

(*b*) The second mode of viewing the process of evolution subordinates the idea of physical cause to that of final cause. The force which effects the continual production and transformation of things is conceived of more or less distinctly after the analogy of a rational impulse towards an end, and the process is regarded as determined or conditioned by this element of purpose.

This teleological view of evolution may be found in a number of systems of nature, which look on the material world as at once bodily and vital or spiritual, though it is often difficult to say whether any particular system should be called dualistic or monistic (in the narrow sense). Thus we have the evolution of the physical world referred to a vital principle which pervades all matter, and of which the essential nature is productivity, to a formative plastic principle which moulds the dead material into various shapes, to an organizing cosmic force, and so on. In all these conceptions, which appear to aim more especially at an explanation of organic forms and life, the element of purpose appears in a nascent shape. Nature is personified as a worker who aims unconsciously and instinctively at some dimly descried end, such as the most various production, the progressive manifestation of life, and so on. In some of these systems, notably in the Aristotelian, the genesis of conscious mind is explained along with that of organic life by means of the supposition that mind is but the formative principle of the individual organism.

The idea of purpose becomes more definite, and, at the same time, a further step is taken towards the explanation of mental life as a development out of physical, in those systems which project a distinct spiritual principle into nature. The way in which this is frequently done is by means of the theory of a world-soul which animates the whole of the material world and directs all parts of its evolution. When this spiritual principle is regarded not only as the formative force, but also as the substantial source of conscious mental life, which has eternally coexisted with matter, we have, as already remarked, a pantheistic conception of evolution which, like another and cognate conception already referred to, approximates to one form of the emanation theory.

The full development of this way of regarding the world and its evolution as the work of a spiritual principle aiming towards an end is to be found in certain doctrines of Objective Idealism, which resolve all material existence into a mode of mental existence—will and thought. These theories clearly simplify the conception of evolution to the utmost, by the identification both of the substantial reality which enters into all parts of the world-process, and of the rationale of all parts of the process itself. In the systems now referred to, the mechanical idea is wholly taken up into the teleological. Purpose is the highest law of things, and it is one purpose which manifests itself through all stages of the world's evolution,—in the region of inorganic nature, of organic life, and of human history. The first genesis of conscious life is explained as a particular moment in this process. In some spiritualistic systems an attempt is made to combine the mechanical (causal) and teleological ideas under the notion of logical development. Yet as a rule the teleological way of conceiving the process predominates.

(*c*) The systems which seek to combine the teleological and the mechanical view of evolution are for the most part based on the monistic idea that the material and the mental are two equally real aspects of one thing. It is clear that this conception of reality provides a way of doing justice to both modes of looking at evolution. In this manner the systems now spoken of are able to regard all parts of evolution as identical in nature, being alike links in a chain of purposeful effects.

This way of regarding the world in its process of evolution will vary according to the particular view of the one reality underlying material and mental phenomena. Thus we may have a universalistic conception of evolution as the two-sided activity of one undivided substance. This idea passes easily into a pantheistic view of the world-process as determined by a divine reason which is also the principle of necessity. In the second place, we may have an individualistic conception of this two-sided process, according to which the world arises out of the unceasing activity of an indefinite number of elements endowed with motion and sensation, and so comprehending a mechanical and a teleological factor. It has already been remarked, however, that this conception may be combined with a strictly mechanical view of evolution.

History of the Idea of Evolution.—The doctrine of evolution in its finished and definite form is a modern product. It required for its formation an amount of scientific knowledge which could only be very gradually acquired. It is vain, therefore, to look for clearly defined and systematic presentations of the idea among ancient writers. On the other hand, nearly all systems of philosophy have discussed the problems underlying evolution. Such questions as the origin of the cosmos as a whole, the production of organic beings and of conscious minds, and the meaning of the observable grades of creation, have from the dawn of speculation occupied men's minds; and the answers to these questions often imply a vague recognition of the idea of a gradual evolution of things. Accordingly, in tracing the antecedents of the modern philosophic doctrine we shall have to glance at most of the principal systems of cosmology, ancient and modern. Yet since in these systems the two inquiries into the *esse* and *fieri* of the world are rarely distinguished with any precision, it will be necessary to indicate very briefly the general outlines of the system so far as they are necessary for understanding their bearing on the problems of evolution.

Mythological Interpretation.—The problem of the origin of the world was the first to engage man's speculative activity. Nor was this line of inquiry pursued simply as a step in the more practical problem of man's final destiny. The order of ideas observable in children suggests the reflection that man began to discuss the "whence" of existence before the "whither." At first, as in the case of the child, the problem of the genesis of things was conceived anthropomorphically: the question "How did the world arise?" first shaped itself to the human mind under the form "Who made the world?" As long as the problem was conceived in this simple manner there was, of course, no room for the idea of a necessary self-conditioned evolution. Yet the first indistinct germ of such an idea appears to emerge in combination with that of creation in some of the ancient systems of theogony. (See article COSMOGONY.) Thus, for example, in the myth of the ancient Parsees, the gods Ormuz and Ahriman are said to evolve themselves out of a primordial matter. It may be supposed that these crude fancies embody a dim recognition of the physical forces and objects personified under the forms of deities, and a rude attempt to account for their genesis as a natural process. These first unscientific ideas of a genesis of the permanent objects of nature took as their pattern the process of organic reproduction and development, and this, not only because these objects were regarded as personalities, but also because this particular mode of becoming would most impress these early observers. This same way of looking at the origin of the material world is illustrated in the Egyptian notion of a cosmic egg out of which issues the god (Phta) who creates the world.

Indian Philosophy.—Passing from mythology to speculation properly so called, we find in the early systems of philosophy of India theories of emanation which approach in some respects the idea of evolution. Brahma is conceived as the eternal self-existent being, which on its material side unfolds itself to the world by gradually condensing itself to material objects through the gradations of ether, fire, water, earth, and the elements. At the same time this eternal being is conceived as the all-embracing world-soul from which emanates the hierarchy of individual souls. In the later system of emanation of Sankhja there is a more marked approach to a materialistic doctrine of evolution. If, we are told, we follow the chain of causes far enough back we reach unlimited eternal creative nature or matter. Out of this "principal thing" or "original nature" all material and spiritual existence issues, and into it will return. Yet this primordial creative nature is endowed with volition with regard to its own development. Its first emanation as plastic nature contains the original soul or deity out of which all individual souls issue.

Early Greek Physicists.—Passing by Buddhism, which, though teaching the periodic destruction of our world by fire, etc., does not seek to determine the ultimate origin of the cosmos, we come to those early Greek physical philosophers who distinctly set themselves to eliminate the idea of divine interference with the world by representing its origin and changes as a natural process. The early Ionian physicists, including Thales, Anaximander, and Anaximenes, seek to explain the world as generated out of a primordial matter which is at the same time the universal support of things. This substance is endowed with a generative or transmutative force[1] by virtue of which it passes into a succession of forms. They thus resemble modern evolutionists, since they regard the world with its infinite variety of forms as issuing from a simple mode of matter. More especially the cosmology of Anaximander resembles the modern doctrine of evolution in its conception of the indeterminate (τὸ ἄπειρον) out of which the particular forms of the cosmos are differentiated. Again, Anaximander may be said to prepare the way for more modern conceptions of material evolution by regarding his primordial substance as eternal, and by looking on all generation as alternating with destruction, each step of the process being of course simply a transformation of the indestructible substance. Once more, the notion that this indeterminate body contains potentially in itself the fundamental contraries—hot, cold, etc.,—by the excretion or evolution of which definite substances were generated, is clearly a forecasting of that antithesis of potentiality and actuality which from Aristotle downwards has been made the basis of so many theories of development. In conclusion, it is noteworthy that though resorting to utterly fanciful hypotheses respecting the order of the development of the world, Anaximander agrees with modern evolutionists in conceiving the heavenly bodies as arising out of an aggregation of diffused matter, and in assigning to organic life an origin in the inorganic materials of the primitive earth (pristine mud). The doctrine of Anaximenes, who unites the conceptions of a determinate and indeterminate original substance adopted by Thales and Anaximander in the hypothesis of a primordial and all-generating air, is a clear advance on these theories, inasmuch as it introduces the scientific idea of condensation and rarefaction as the great generating or transforming agencies. For the rest, his theory is chiefly important as emphasizing the vital character of the original substance. The primordial air is conceived as animated. Anaximenes seems to have inclined to a view of cosmic evolution as throughout involving a quasi-spiritual factor. This idea of the air as the original principle and source of life and intelligence is much more clearly expressed by a later writer, Diogenes of Apollonia. Diogenes made this conception of a vital and intelligent air the ground of a teleological view of climatic and atmospheric phenomena. It is noteworthy that he sought to establish the identity of organic and inorganic matter by help of the facts of vegetal and animal nutrition. Diogenes distinctly taught that the world is of finite duration, and will be renewed out of the primitive substance.

Pythagoreans.—We may pass by that curious mode of conceiving the world as a development out of numbers regarded as active principles which was adopted by the Pythagoreans, since it is too remote from modern conceptions of cosmic evolution.[2]

Eleatics.—The Eleatics, Xenophanes, Parmenides, and Zeno, need to be referred to here simply on the ground of their denial of all plurality and individuality in objects and of any real process of change, development, or transformation in the world. It may be added, however, that both Xenophanes and Parmenides have their way of regarding the origin of the cosmos and of animal and human life, though these conjectures are put forward as matters of "opinion," having to do with the illusory impressions of the senses only.

Heraclitus.—The next Greek thinker, Heraclitus, deserves a prominent place in a history of the idea of evolution. This writer distinctly sides with the Ionian physicists, as against the Eleatics, by asserting the reality of motion, change, and generation. He differs from the former, as Grote observes, by regarding the problem of change rather as one of ontology than of physics. Heraclitus conceives of the incessant process of flux in which all things are involved as consisting of two sides or moments—generation and decay—which are regarded as a confluence of opposite streams. In thus making transition or change, viewed as the identity of existence and non-existence, the leading idea of his system, Heraclitus anticipated in some measure Hegel's peculiar doctrine of evolution as a dialectic process.[1] At the same time, we may find expressed in figurative language the germs of thoughts which enter into still newer doctrines of evolution. For example, the notion of conflict (*πόλεμος*) as the father of all things and of harmony as arising out of a union of discords,[2] and again of an endeavor by individual things to maintain themselves in permanence against the universal process of destruction and renovation, cannot but remind one of certain fundamental ideas in Mr. Darwin's theory of evolution. According to Grote, it is doubtful how far Heraclitus intended to supply by his idea of fire a physical, as distinguished from a metaphysical, doctrine of the world-process.

---

[1] According to Ueberweg (who calls their systems Hylozoism), they all conceived of this matter as vital.

[2] Grote calls attention to an analogue of this notion of number in Oken's *Elements of Physio-Philosophy*. See his *Plato*, i. p. 10, note E.

Empedocles.—Empedocles took an important step in the direction of modern conceptions of physical evolution by teaching that all things arise, not by transformations of some primitive form of matter, but by various combinations of a number of permanent elements. Further, by maintaining that the elements are continually being combined and separated by the two forces love and hatred, which appear to represent in a figurative way the physical forces of attraction and repulsion, Empedocles may be said to have made a considerable advance in the construction of the idea of evolution as a strictly mechanical process. It may be observed, too, that the hypothesis of a primitive compact mass (*sphærus*), in which love (attraction) is supreme, has some curious points of similarity to, and contrast with, that notion of a primitive nebulous matter with which the modern doctrine of cosmic evolution usually sets out. Empedocles tries to explain the genesis of organic beings, and, according to Lange, anticipates the idea of Mr. Darwin that adaptations abound, because it is their nature to perpetuate themselves. He further recognizes a progress in the production of vegetable and animal forms, though this part of his theory is essentially crude and unscientific. More important in relation to the modern problems of evolution is his thoroughly materialistic way of explaining the origin of sensation and knowledge by help of his peculiar hypothesis of effluvia and pores. The supposition that sensation thus rests on a material process of absorption from external bodies naturally led up to the idea that plants and even inorganic substances are percipient, and so to an indistinct recognition of organic life as a scale of intelligence.

Anaxagoras.—The doctrine of Homœmeries, propounded by Anaxagoras, agrees with that of Empedocles in assigning the origin of things to combinations and redistributions of certain primordial forms of matter. Yet these are less simple than the elements of the other thinker.[3] Moreover, the idea that the diversity of things arises from a preponderance of certain elements, and not from the mere fact of various combination, removes the theory of Anaxagoras further from modern conceptions of cosmic evolution than that of Empedocles.[4] According to Grote's interpretation, Anaxagoras, in his conception of nous as the originator of movement and order which manifests itself as the vital principle in plants as well as in animals and man, would appear to lean rather to a monistic and purely materialistic than to a dualistic conception of evolution.

Atomists.—In the theory of Atomism taught by Leucippus and Democritus we have the basis of the modern mechanical conceptions of cosmic evolution. Here the endless harmonious diversity of our cosmos, as well as of other worlds supposed to co-exist with our own, is said to arise through the various combination of indivisible material elements differing in figure and magnitude only. The force which brings the atoms together in the forms of objects is inherent in the elements, and all their motions are necessary. The origin of things, which is also their substance, is thus laid in the simplest and most homogeneous elements or principles. The real world thus arising consists only of diverse combinations of atoms, having the properties of magnitude, figure, weight, and hardness, all other qualities being relative only to the sentient organism. The problem of the genesis of mind is practically solved by identifying the soul, or vital principle, with heat or fire which pervades in unequal proportions, not only man and animals, but plants and nature as a whole, and through the agitation of which by incoming effluvia all sensation arises.

The Sophists—Critias.—Of the Sophists there is but one whose doctrines need concern us here, namely, Critias. In a fragment of his writings we meet with a speculation on the past development of man, which is curious as distinctly recognizing the upward direction of human history, and so as contrasting with the prevailing view of this history as a gradual deterioration. Critias tells us there was a time when the life of man was lawless (*ἄτακτος*) and beast-like (*θηριώδης*), when he was a slave of force, and when no honor was paid to the good nor punishment administered to the bad. Laws having arisen, evil actions which could no longer be done overtly were still practised in secret, and at this stage a wise man arose who sought to instil terror into the minds of the people, and so conceived the Deity, who is made the more terrible by being localized in the region whence proceed thunder and lightning.

Plato.—Plato needs to be referred to here only because of the strongly marked opposition of his philosophy to the teaching of evolution. It is true (as Zeller remarks) that Plato's whole philosophy was directed less to the explanation of becoming than to the consideration of being. So far, however, as the highly mythical cosmology of the *Timæus* may be taken as indicating Plato's way of looking at the successive order of the world, we see that it widely deviates from that of the evolutionist. Thus the notion of the Demiurgus is distinctly contradictory of the idea of a natural process of evolution. Again, the supposition that the world of particular things is somehow determined by pre-existing universal ideas lends itself rather to a theory of emanation as a descent from the more perfect to the less perfect than to a doctrine of evolution. It became the basis of that doctrine of universal essences or types which for ages interfered with a scientific explanation of organic forms. Again Plato exactly reverses the order of evolution in his way of looking at the scale of organic beings and souls, since he sets out with the highest and most perfect, the divine cosmos, and passes downwards to man and the lower animals viewed as successive degradations.

Early Platonists.—Among the early followers of Plato, Speusippus deserves mention here in so far as he assimilated the course of the world to the development of the individual by regarding it as a progress from imperfection to perfection.[5] Xenocrates again appears to have viewed the whole of the cosmos as a graduated scale of animate existence.

Aristotle.—Aristotle is much nearer a conception of evolution than his master. It is true he sets out with a transcendent Deity, and follows Plato in viewing the creation of the cosmos as a process of descent from the more to the less perfect according to the distance from the original self-moving agency. Yet on the whole Aristotle leans to a teleological theory of evolution, which he interprets dualistually by means of certain metaphysical distinctions. Thus even his idea of the relation of the divine activity to the world shows, as Zeller and Lange remark, a tendency to a pantheistic notion of a divine thought which gradually realizes itself in the process of becoming. Aristotle's distinction of form and matter, and his conception of becoming as a transition from actuality to potentiality, provides a new ontological way of conceiving the process of material and organic evolution.[1] To Aristotle the whole of nature is instinct with a vital impulse towards some higher manifestation. Organic life presents itself to him as a progressive scale of complexity determined by its final end, namely, man.[2] In some respects Aristotle approaches the modern view of evolution. Thus, though he looked on species as fixed, being the realization of an unchanging formative principle (*φύσις*), he seems, as Ueberweg observes, to have inclined to entertain the possibility of a spontaneous generation in the case of the lowest organisms. Aristotle's teleological conception of organic evolution often approaches modern mechanical conceptions. Thus he says that nature fashions organs in the order of their necessity, the first being those essential to life. So, too, in his psychology he speaks of the several degrees of mind as arising according to a progressive necessity.[3] In his view of touch and taste, as the two fundamental and essential senses, he may remind one of Mr. Spencer's doctrine. At the same time Aristotle precludes the idea of a natural development of the mental series by the supposition that man contains, over and above a natural finite soul inseparable from the body, a substantial and eternal principle (*νοῦς*) which enters into the individual from without. Aristotle's brief suggestions respecting the origin of society and governments in the *Politics* show a leaning to a naturalistic interpretation of human history as a development conditioned by growing necessities.

---

[1] This is brought out by F. Lassalle, *Die Philosophie Herakleitos*, p. 126.

[2] Zeller observes that Heraclitus fails to tell us what are the elements which conflict.

[3] Grote says the idea of these multifarious forms of matter was suggested by the phenomena of animal nutrition.—*Plato*, i. 55.

[4] It is observed by Ferrier that the doctrine of Anaxagoras reverses the order of the Atomists, by regarding the transition as one from the complex to the seemingly simple. It is no doubt true that the chief aim of Anaxagoras was to explain not so much the diversity as the orderly arrangement of individual things. Yet his conception of the primal chaos involves at least the notion of an apparent homogeneity or uniformity, no particles being distinguishable from the rest. (See Grote, *op. cit.*, i. 51.) Grote even assimilates the chaos of Anaxagoras to the primordial indeterminate of Anaximander.

[5] Speusippus differed from Plato by making good the end and not the efficient cause of being (see Zeller, *Plato*, p. 568 *sq.*).

Strato.—Of Aristotle's immediate successors one deserves to be noticed here, namely, Strato of Lampsacus, who developed his master's cosmology into a system of naturalism. Strato appears to reject Aristotle's idea of an original source of movement and life extraneous to the world in favor of an immanent principle. All parts of matter have an inward plastic life whereby they can fashion themselves to the best advantage, according to their capability, though not with consciousness.

The Stoics.—In the cosmology of the Stoics we have the germ of a monistic and pantheistic conception of evolution. All things are said to be developed out of an original being, which is at once material (fire) and spiritual (the Deity), and in turn they will dissolve back into this primordial source. At the same time the world as a developed whole is regarded as an organism which is permeated with the divine Spirit, and so we may say that the world-process is a self-realization of the divine Being. The formative principle or force of the world is said to contain the several rational germinal forms of things. Individual things are supposed to arise out of the original being, as animals and plants out of seeds. Individual souls are an efflux from the all-compassing world-soul. The necessity in the world's order is regarded by the Stoics as identical with the divine reason, and this idea is used as the basis of a teleological and optimistic view of nature. Very curious, in relation to modern evolutional ideas, is the Stoical doctrine that our world is but one of a series of exactly identical ones, all of which are destined to be burnt up and destroyed.

The Epicureans — Lucretius.—The Epicureans differed from the Stoics by adopting a purely mechanical view of the world-process. Their fundamental conception is that of Democritus; they seek to account for the formation of the cosmos, with its order and regularity, by setting out with the idea of an original (vertical) motion of the atoms, which somehow or other results in movements towards and from one another. Our world is but one of an infinite number of others, and all the harmonies and adaptations of the universe are regarded as a special case of the infinite possibilities of mechanical events. Lucretius regards the primitive atoms (first beginnings or first bodies) as seeds out of which individual things are developed. All living and sentient things are formed out of insentient atoms (*e.g.*, worms spring out of dung). The peculiarity of organic and sentient bodies is due to the minuteness and shape of their particles, and to their special motions and combinations. So, too, mind consists but of extremely fine particles of matter, and dissolves into air when the body dies. Lucretius traces, in the fifth book of his poem, the progressive genesis of vegetal and animal forms out of the mother-earth. He vaguely anticipates the modern idea of the world as a survival of the fittest when he says that many races may have lived and died out, and that those which still exist have been protected either by craft, courage, or speed. Lucretius touches on the development of man out of a primitive, hardy, beast-like condition. Pregnant hints are given respecting a natural development of language which has its germs in sounds of quadrupeds and birds, of religious ideas out of dreams and waking hallucinations, and of the art of music by help of the suggestion of natural sounds. Lucretius thus recognizes the whole range of existence to which the doctrine of evolution may be applied.

Neo-Platonists.—In the doctrines of the Neo-Platonists, of whom Plotinus is the most important, we have the world-process represented after the example of Plato as a series of descending steps, each being less perfect than its predecessors, since it is further removed from the first cause.[4] The system of Plotinus, Zeller remarks, is not strictly speaking one of emanation, since there is no communication of the divine essence to the created world; yet it resembles emanation inasmuch as the genesis of the world is conceived as a necessary physical effect, and not as the result of volition. In Proclus we find this conception of an emanation of the world out of the Deity, or the absolute, made more exact, the process being regarded as threefold —(1) persistence of cause in effect, (2) the departure of effect from cause, and (3) the tendency of effect to revert to its cause.

The Fathers.—The speculations of the fathers respecting the origin and course of the world seek to combine Christian ideas of the Deity with doctrines of Greek philosophy. The common idea of the origin of things is that of an absolute creation of matter and mind alike. The course of human history is regarded by those writers who are most concerned to refute Judaism as a progressive divine education. Among the Gnostics we meet with the hypothesis of emanation, as, for example, in the curious cosmic theory of Valentinus.

Middle Ages — Early Schoolmen. — In the speculative writings of the Middle Ages, including those of the schoolmen, we find no progress towards a more accurate and scientific view of nature. The cosmology of this period consists for the most part of the Aristotelian teleological view of nature combined with the Christian idea of the Deity and His relation to the world. In certain writers, however, there appears a more elaborate transformation of the doctrine of creation into a system of emanation. According to John Scotus Erigena, the nothing out of which the world is created is the divine essence. Creation is the act by which God passes through the primordial causes, or universal ideas, into the region of particular things (*processio*), in order finally to return to himself (*reversio*). The transition from the universal to the particular is of course conceived as a descent or degradation. A similar doctrine of emanation is to be found in the writings of Bernhard of Chartres, who conceives the process of the unfolding of the world as a movement in a circle from the most general to the individual, and from this back to the most general. This movement is said to go forth from God to the animated heaven, stars, visible world, and man, which represent decreasing degrees of cognition.

Arab Philosophers.—Elaborate doctrines of emanation, largely based on Neo-Platonic ideas, are also propounded by some of the Arabic philosophers, as by Alfarabi and Avicenna. The leading thought is that of a descending series of intelligences, each emanating from its predecessor, and having its appropriate region in the universe.

Jewish Philosophy.—In the Jewish speculations of the Middle Ages may be found curious forms of the doctrine of emanations, uniting the Biblical idea of creation with elements drawn from the Persians and the Greeks. In the later and developed form of the Cabala, the origin of the world is represented as a gradually descending emanation of the lower out of the higher. Among the philosophic Jews, the Spanish Avicebron, in his *Fons Vitæ*, expounds a curious doctrine of emanation. Here the divine will is viewed as an efflux from the divine wisdom, as the intermediate link between God, the first substance and all things, and as the fountain out of which all forms emanate. At the same time all forms, including the higher intelligible ones, are said to have their existence only in matter. Matter is the one universal substance, body and mind being merely specifications of this. Thus Avicebron approaches, as M. Munk observes,[1] a pantheistic conception of the world, though he distinctly denies both matter and form to God.

---

[1] Zeller says that through this distinction Aristotle first made possible the idea of development.

[2] See this well brought out in Mr. G. H. Lewes's *Aristotle*, p. 187.

[3] Grote calls attention to the contrast between Plato's and Aristotle's way of conceiving the gradations of mind (*Aristotle*, ii. 171).

[4] Zeller observes that this scale of decreasing perfection is a necessary consequence of the idea of a transcendent deity.

Later Scholastics.—Passing now to the later schoolmen, a bare mention must be made of Thomas, who elaborately argues for the absolute creation of the world out of nothing, and of Albertus Magnus, who reasons against the Aristotelian idea of the past eternity of the world. More importance attaches to Duns Scotus, who brings prominently forward the idea of a progressive development in nature by means of a process of determination. The original substance of the world is the *materia primo-prima*, which is the immediate creation of the Deity. This serves Duns Scotus as the most universal basis of existence, all angels having material bodies. This matter is differentiated into particular things (which are not privations but perfections) through the addition of an individualizing principle (*hæcceitas*) to the universal (*quidditas*). The whole world is represented by the figure of a tree, of which the seeds and roots are the first indeterminate matter, the leaves the accidents, the twigs and branches corruptible creatures, the blossoms the rational soul, and the fruit pure spirits or angels. It is also described as a bifurcation of two twigs, mental and bodily creation out of a common root. One might almost say that Duns Scotus recognizes the principle of a gradual physical evolution, only that he chooses to represent the mechanism by which the process is brought about by means of quaint scholastic fictions.

Revival of Learning.—The period of the revival of learning, which was also that of a renewed study of nature, is marked by a considerable amount of speculation respecting the origin of the universe. In some of these we see a return to Greek theories, though the influence of physical discoveries, more especially those of Copernicus, Kepler, and Galileo, is distinctly traceable.

Telesio.—An example of a return to early Greek speculation is to be met with in Bernardino Telesio. By this writer the world is explained as a product of three principles,—dead matter, and two active forces, heat and cold. Terrestrial things arise through a confluence of heat, which issues from the heavens, and cold, which comes from the earth. Both principles have sensibility, and thus all products of their collision are sentient, that is, feel pleasure and pain. The superiority of animals to plants and metals in the possession of special organs of sense is connected with the greater complexity and heterogeneity of their structure.

Giordano Bruno.—In the system of Giordano Bruno, who sought to construct a philosophy of nature on the basis of new scientific ideas, more particularly the doctrine of Copernicus, we find the outlines of a theory of cosmic evolution conceived as an essentially vital process. Matter and form are here identified, and the evolution of the world is presented as the unfolding of the world-spirit to its perfect forms according to the plastic substratum (matter) which is but one of its sides. This process of change is conceived as a transformation, in appearance only, of the real unchanging substance (matter and form). All parts of matter are capable of developing into all forms; thus the materials of the table and chair may, under proper circumstances, be developed to the life of the plant or of the animal. The elementary parts of existence are the *minima*, or monads, which are at once material and mental. On their material side they are not absolutely unextended, but spherical. Bruno looked on our solar system as but one out of an infinite number of worlds. His theory of evolution is essentially pantheistic, and he does not employ his hypothesis of monads in order to work out a more mechanical conception.

Campanella.—A word must be given to one of Bruno's contemporary compatriots, namely Campanella, who gave poetic expression to that system of universal vitalism which Bruno developed. He argues, from the principle *quicquid est in effectibus esse et in causis*, that the elements and the whole world have sensation, and thus he appears to derive the organic part of nature out of the so-called "inorganic."

Boehme.—Another writer of this transition period deserves a passing reference here, namely, Jacob Boehme the mystic, who by his conception of a process of inner diremption as the essential character of all mind, and so of God, prepared the way for later German theories of the origin of the world as the self-differentiation and self-externalization of the absolute spirit.

Hobbes and Gassendi.—The influence of an advancing study of nature, which was stimulated if not guided by Bacon's writings, is seen in the more careful doctrines of materialism worked out almost simultaneously by Hobbes and Gassendi. These theories, however, contain little that bears directly on the hypothesis of a natural evolution of things. In the view of Hobbes, the difficulty of the genesis of conscious minds is solved by saying that sensation and thought are part of the reaction of the organism on external movement. Yet Hobbes appears (as Clarke points out) to have vaguely felt the difficulty; and in a passage of his *Physics* (chap. 25, sect. 5) he says that the universal existence of sensation in matter cannot be disproved, though he shows that when there are no organic arrangements the mental side of the movement (*phantasma*) is evanescent. The theory of the origin of society put forth by Hobbes, though directly opposed in most respects to modern ideas of social evolution, deserves mention here by reason of its enforcing that principle of struggle (*bellum omnium contra omnes*) which has played so conspicuous a part in recent doctrines of evolution. Gassendi, with some deviations, follows Epicurus in his theory of the formation of the world. The world consists of a finite number of atoms, which have in their own nature a self-moving force or principle. These atoms, which are the seeds of all things, are, however, not eternal but created by God. Gassendi distinctly argues against the existence of a world-soul or a principle of life in nature.

Descartes.—In the philosophy of Descartes we meet with a dualism of mind and matter which does not easily lend itself to the conception of evolution. His doctrine that consciousness is confined to man, the lower animals being unconscious machines (*automata*), excludes all idea of a progressive development of mind. Yet Descartes, in his *Principia Philosophia*, laid the foundation of the modern mechanical conception of nature and of physical evolution. In the third part of this work he inclines to a thoroughly natural hypothesis respecting the genesis of the physical world, and adds in the fourth part that the same kind of explanation might be applied to the nature and formation of plants and animals. He is indeed careful to keep right with the orthodox doctrine of creation by saying that he does not believe the world actually arose in this mechanical way out of the three kinds of elements which he here supposes, but that he simply puts out his hypothesis as a mode of conceiving how it might have arisen. Descartes's account of the mind and its passions is thoroughly materialistic, and to this extent he works in the direction of a materialistic explanation of the origin of mental life.

Spinoza.—In Spinoza's pantheistic theory of the world, which regards thought and extension as but two sides of one substance, the problem of becoming is submerged in that of being. Although Spinoza's theory attributes a mental side to all physical events, he rejects all teleological conceptions and explains the order of things as the result of an inherent necessity. He recognizes gradations of things according to the degree of complexity of their movements and that of their conceptions. To Spinoza (as Kuno Fischer observes) man differs from the rest of nature in the degree only and not in the kind of his powers. So far Spinoza approaches the conception of evolution. He may be said to furnish a further contribution to a metaphysical conception of evolution in his view of all finite individual things as the infinite variety to which the unlimited productive power of the universal substance gives birth. Mr. F. Pollock has taken pains to show in more than one essay how nearly Spinoza approaches certain ideas contained in the modern doctrine of evolution, as for example that of self-preservation as the determining force in things.

Cudworth.—One or two English writers belonging to the latter part of the 17th century must be glanced at here. Of these the first is Cudworth, who, in his work *The True Intellectual System of the Universe*, elaborately criticises the various "atheistic" modes of explaining the origin and form of the world as a natural process. Cudworth emphasizes especially the difficulty of explaining the rise of consciousness, and seeks to show how the early Greek atomical physiologists were driven to assume a spiritual principle over and above their material elements. He dwells on the signs of purpose in nature, and argues that no fortuitous combination of elements could have sufficed to produce that balance of male and female individuals on which the preservation of species depends. Yet though thus an anti-evolutionist, Cudworth provides a way of interpreting the evolution of life by means of an immanent principle, since he refers the forms of nature to a plastic principle, which does not involve consciousness, though it may be called a drowsy unawakened cognition.

---

[1] *Mélanges de philosophie juive et arabe*, p. 225.

Locke.—In Locke we find, with a retention of certain anti-evolutionist ideas, a marked tendency to this mode of viewing the world. To Locke the universe is the result of a direct act of creation, even matter being limited in duration and created. Even if matter were eternal it would, he thinks, be incapable of producing motion; and if motion is itself conceived as eternal, thought can never begin to be. The first eternal being is thus spiritual or "cogitative," and contains in itself all the perfections that can ever after exist. He repeatedly insists on the impossibility of senseless matter putting on sense.[1] Yet while thus placing himself at a point of view opposed to that of a gradual evolution of the organic world, Locke prepared the way for this doctrine in more ways than one. First of all, his genetic method as applied to the mind's ideas—which laid the foundations of English analytical psychology—was a step in the direction of a conception of mental life as a gradual evolution. Again he works towards the same end in his celebrated refutation of the scholastic theory of real specific essences. In this argument he emphasizes the vagueness of the boundaries which mark off organic species with a view to show that these do not correspond to absolutely fixed divisions in the objective world, that they are made by the mind, not by nature.[2] This idea of the continuity of species is developed more fully in a remarkable passage (*Essay*, bk. iii. ch. vi. § 12), where he is arguing in favor of the hypothesis, afterwards elaborated by Leibnitz, of a graduated series of minds (species of spirits) from the Deity down to the lowest animal intelligence. He here observes that "all quite down from us the descent is by easy steps, and a continued series of things, that in each remove differ very little from one another." Thus man approaches the beasts, and the animal kingdom is nearly joined with the vegetable, and so on down to the lowest and "most inorganical parts of matter." Finally, it is to be observed that Locke had a singularly clear view of organic arrangements (which of course he explained according to a theistic teleology) as an adaptation to the circumstances of the environment or to "the neighborhood of the bodies that surround us." Thus he suggests that man has not eyes of a microscopic delicacy, because he would receive no great advantage from such acute organs, since though adding indefinitely to his speculative knowledge of the physical world they would not practically benefit their possessor (*e.g.*, by enabling him to avoid things at a convenient distance).[3]

Idea of Progress in History.—Before leaving the 17th century we must just refer to the writers who laid the foundations of the essentially modern conception of human history as a gradual upward progress. According to Prof. Flint,[4] there were four men who in this century seized and made prominent this idea, namely, Bodin, Bacon, Descartes, and Pascal. The former distinctly argues against the idea of a deterioration of man in the past. In this way we see that just as advancing natural science was preparing the way for a doctrine of physical evolution, so advancing historical research was leading to the application of a similar idea to the collective human life.

English Writers of the 18th Century—Hume.—The theological discussions which make up so large a part of the English speculation of the last century cannot detain us here. There is, however, one writer who sets forth so clearly the alternative suppositions respecting the origin of the world that he claims a brief notice. We refer to David Hume. In his *Dialogues concerning Natural Religion* he puts forwards tentatively, in the person of one of his interlocutors, the ancient hypothesis that since the world resembles an animal or vegetal organism rather than a machine, it might more easily be accounted for by a process of generation than by an act of creation. Later on he develops the materialistic view of Epicurus, only modifying it so far as to conceive of matter as finite. Since a finite number of particles is only susceptible of finite transpositions, it must happen (he says), in an eternal duration that every possible order or position will be tried an infinite number of times, and hence this world is to be regarded (as the Stoics maintained) as an exact reproduction of previous worlds. The speaker seeks to make intelligible the appearance of art and contrivance in the world as a result of a natural settlement of the universe (which passes through a succession of chaotic conditions) into a stable condition, having a constancy in its forms, yet without its several parts losing their motion and fluctuation.

Priestley.—The English materialists of the latter part of the century did little to work out the idea of evolution. Priestley needs to be mentioned here only by reason of his clear recognition of human progress.

Monboddo.—Of other British writers of the period, Lord Monboddo must be named on account of his curious speculations respecting the origin of man. In his *Ancient Metaphysics* (vol. iii.), Monboddo conceives man as gradually elevating himself from an animal condition, in which his mind is immersed in matter, to a state in which mind acts independently of body. In his equally voluminous work, *The Origin and Progress of Language*, Monboddo brings man under the same species as the orang-outang. He traces the gradual elevation of man to the social state, which he conceives as a natural process determined by "the necessities of human life." He looks on language (which is not "natural" to man in the sense of being necessary to his self-preservation) as a consequence of his social state.

French Writers of the 18th Century.—Let us now pass to the French writers of the last century. Here we are first struck by the results of advancing physical speculation in their bearing on the conception of the world. Careful attempts, based on new scientific truths, are made to explain the genesis of the world as a natural process. Maupertuis, who, together with Voltaire, introduced the new idea of the universe as based on Newton's discoveries, sought to account for the origin of organic things by the hypothesis of sentient atoms. Buffon the naturalist speculated, not only on the structure and genesis of organic beings, but also on the course of formation of the earth and solar system, which he conceived after the analogy of the development of organic beings out of seed. Diderot, too, in his varied intellectual activity, found time to speculate on the genesis of sensation and thought out of a combination of matter endowed with an elementary kind of sentience. De la Mettrie worked out a materialistic doctrine of the origin of things, according to which sensation and consciousness are nothing but a development out of matter. He sought (*L'homme-machine*) to connect man in his original condition with the lower animals, and emphasized (*L'homme-plante*) the essential unity of plan of all living things. Helvetius, in his work on man, referred all differences between our species and the lower animals to certain peculiarities of organization, and so prepared the way for a conception of human development out of lower forms as a process of physical evolution. Charles Bonnet met the difficulty of the origin of conscious beings much in the same way as Leibnitz, by the supposition of eternal minute organic bodies to which are attached immortal souls. Yet though in this way opposing himself to the method of the modern doctrine of evolution, he aided the development of this doctrine by his view of the organic world as an ascending scale from the simple to the complex. Robinet, in his treatise *De la Nature*, worked out the same conception of a gradation in organic existence, connecting this with a general view of nature as a progress from the lowest inorganic forms of matter up to man. The process is conceived as an infinite series of variations or specifications of one primitive and common type. Man is the *chef d'œuvre* of nature, which the gradual progression of beings was to have as its last term, and all lower creations are regarded as pre-conditions of man's existence, since nature "could only realize the human form by combining in all imaginable ways each of the traits which was to enter into it." The formative force in this process of evolution (or "metamorphosis") is conceived as an intellectual principle (*idée génératrice*). Robinet thus laid the foundation of that view of the world as wholly vital, and as a progressive unfolding of a spiritual formative principle, which was afterwards worked out by Schelling. It is to be added that Robinet adopted a thorough-going materialistic view of the dependence of mind on body, going even to the length of assigning special nerve-fibres to the moral sense. The system of Holbach seeks to provide a consistent materialistic view of the world and its processes. Mental operations are identified with physical movements, the three conditions of physical movement, inertia, attraction, and repulsion, being in the moral world self-love, love, and hate. He left open the question whether the capability of sensation belongs to all matter, or is confined to the combinations of certain materials. He looked on the actions of the individual organism and of society as determined by the needs of self-preservation. He conceived of man as a product of nature that had gradually developed itself from a low condition, though he relinquished the problem of the exact mode of his first genesis and advance as not soluble by data of experience. Holbach thus worked out the basis of a rigorously materialistic conception of evolution.

---

[1] Yet he leaves open the question whether the Deity has annexed thought to matter as a faculty, or whether it rests on a distinct spiritual principle.

[2] Locke half playfully touches on certain monsters, with respect to which it is difficult to determine whether they ought to be called men. (*Essay*, book iii. ch. vi. sect. 26, 27.)

[3] A similar coincidence between the teleological and the modern evolutional way of viewing things is to be met with in Locke's account of the use of pain in relation to the preservation of our being, bk. ii. ch. vii. sect. 4.

[4] *Philosophy of History*, Introduction, p. 28 *sq.*, where an interesting sketch of the growth of the idea of progress is to be found.

The question of human development which Holbach touched on was one which occupied many minds both in and out of France during the past century, and more especially towards its close. The foundations of this theory of history as an upward progress of man out of a barbaric and animal condition were laid by Vico in his celebrated work *Principii di Scienza Nuova.* In France the doctrine was represented by Turgot and Condorcet.

Of the English writers who discussed the question of man's development we have already spoken. The German speculations on the subject will be touched on presently.

German Writers of the 18th Century—Leibnitz.—In Leibnitz we find, if not a doctrine of evolution in the strict sense, a theory of the world which is curiously related to the modern doctrine. The chief aim of Leibnitz is no doubt to account for the world in its static aspect as a co-existent whole, to conceive the ultimate reality of things in such a way as to solve the mystery of mind and matter. Yet by his very mode of solving the problem he is led on to consider the nature of the world-process. By placing substantial reality in an infinite number of monads whose essential nature is force or activity, which is conceived as mental (representation), Leibnitz was carried on to the explanation of the successive order of the world. He prepares the way, too, for a doctrine of evolution by his monistic idea of the substantial similarity of all things, inorganic and organic, bodily and spiritual, and still more by his conception of a perfect gradation of existence from the lowest "inanimate" objects, whose essential activity is confused representation, up to the highest organized being—man—with his clear intelligence.[1] Turning now to Leibnitz's conception of the world as a process, we see first that he supplies, in his notion of the underlying reality as force which is represented as spiritual (*quelque chose d'analogique au sentiment et à l'appétit*), both a mechanical and a teleological explanation of its order. More than this, Leibnitz supposes that the activity of the monads takes the form of a self-evolution. It is the following out of an inherent tendency or impulse to a series of changes, all of which were virtually pre-existent, and this process cannot be interfered with from without. As the individual monad, so the whole system which makes up the world is a gradual development. In this case, however, we cannot say that each step goes out of the other as in that of individual development. Each monad is an original independent being, and is determined to take this particular point in the universe, this place in the scale of beings. We see how different this metaphysical conception is from that scientific notion of cosmic evolution in which the lower stages are the antecedents and conditions of the higher. It is probable that Leibnitz's notion of time and space, which approaches Kant's theory, led him to attach but little importance to the successive order of the world. Leibnitz, in fact, presents to us an infinite system of perfectly distinct though parallel developments, which on their mental side assume the aspect of a scale, not through any mutual action, but solely through the determination of the Deity. Even this idea, however, is incomplete, for Leibnitz fails to explain the physical aspect of development. Thus he does not account for the fact that organic beings—which have always existed as preformations (in the case of animals as *animaux spermatiques*)—come to be developed under given conditions. Yet Leibnitz prepared the way for a new conception of organic evolution. The modern monistic doctrine, that all material things consist of sentient elements, and that consciousness arises through a combination of these, was a natural transformation of Leibnitz's theory.[2]

Lessing.—Of Leibnitz's immediate followers we may mention Lessing, who in his *Education of the Human Race* brought out the truth of the process of gradual development underlying human history, even though he expressed this in a form inconsistent with the idea of a spontaneous evolution.

Herder.—Herder, on the other hand, Lessing's contemporary, treated the subject of man's development in a thoroughly naturalistic spirit. In his *Ideen sur Philosophie der Geschichte*, Herder adopts Leibnitz's idea of a graduated scale of beings, at the same time conceiving of the lower stages as the conditions of the higher. Thus man is said to be the highest product of nature, and as such to be dependent on all lower products. All material things are assimilated to one another as organic, the vitalizing principle being inherent in all matter. The development of man is explained in connection with that of the earth, and in relation to climatic variations, etc. Man's mental faculties are viewed as related to his organization, and as developed under the pressure of the necessities of life.[3]

Kant.—Kant's relation to the doctrine of evolution is a many-sided one. In the first place, his peculiar system of subjective idealism, involving the idea that time is but a mental form to which there corresponds nothing in the sphere of noümenal reality, serves to give a peculiar philosophical interpretation to every doctrine of cosmic evolution. Kant, like Leibnitz, seeks to reconcile the mechanical and teleological views of nature, only he assigns to these different spheres. The order of the inorganic world is explained by properly physical causes. In his *Naturgeschichte des Himmels*, in which he anticipated the nebular theory afterwards more fully developed by Laplace, Kant sought to explain the genesis of the cosmos as a product of physical forces and laws. The worlds, or systems of worlds, which fill infinite space are continually being formed and destroyed. Chaos passes by a process of evolution into a cosmos, and this again into chaos. So far as the evolution of the solar system is concerned, Kant held these mechanical causes as adequate. For the world as a whole, however, he postulated a beginning in time (whence his use of the word creation), and further supposed that the impulse of organization which was conveyed to chaotic matter by the Creator issued from a central point in the infinite space spreading gradually outwards.[4] While in his cosmology Kant thus relies on mechanical conceptions, in his treatment of organic life his mind is, on the contrary, dominated by teleological ideas. An organism was to him something controlled by a formative organizing principle. It was natural, therefore, that he rejected the idea of a spontaneous generation of organisms (which was just then being advocated by his friend Forster), not only as unsupported by experience but as an inadequate hypothesis. Experience forbids our excluding organic activity from natural causes, also our excluding intelligence from purposeful (*zweckthätigen*) causes; hence experience forbids our defining the fundamental force or first cause out of which living creatures arose.[5] Just as Kant thus sharply marks off the regions of the inorganic and the organic, so he sets man in strong opposition to the lower animals. His ascription to man of a unique faculty, free-will, forbade his conceiving our species as a link in a graduated series of organic developments. In his doctrine of human development he does indeed recognize an early stage of existence in which our species was dominated by sensuous enjoyment and instinct. He further conceives of this stage as itself a process of (natural) development, namely, of the natural disposition of the species to vary in the greatest possible manner so as to preserve its unity through a process of self-adaptation (*Anarten*) to climate. This, he says, must not be conceived as resulting from the action of external causes, but is due to a natural disposition (*Analge*). From this capability of natural development (which already involves a teleological idea) Kant distinguishes the power of moral self-development or self-liberation from the dominion of nature, the gradual realization of which constitutes human history or progress. This moral development is regarded as a gradual approach to that rational, social, and political state in which will be realized the greatest possible quantity of liberty. Thus Kant, though he appropriated and gave new form to the idea of human progress, conceived of this as wholly distinct from a natural (mechanical) process. In this particular, as in his view of organic actions, Kant distinctly opposed the idea of evolution as one universal process swaying alike the physical and the moral world.

---

[1] Mr. Lewes points out that Leibnitz is inconsistent in his account of the intelligence of man in relation to that of lower animals, since when answering Locke he no longer regards these as differing in degree only.

[2] Both Mr. Lewes and Prof. Du Bois Reymond have brought out the points of contact between Leibnitz's theory of monads and modern biological speculations (*Hist. of Phil.* ii. 287, and *Leibnitzsche Gedanken in der modernen Naturwissenschaft*, p. 23 *sq.*).

[3] For Herder's position in relation to the modern doctrine of evolution see F. von Bärenbach's *Herder als Vorgänger Darwins*, a work which tends to exaggerate the proximity of the two writers.

[4] Kant held it probable that other planets besides our earth are inhabited, and that their inhabitants form a scale of beings, their perfection increasing with the distance of the planet which they inhabit from the sun.

[5] Kant calls the doctrine of the transmutation of species a "hazardous fancy of the reason." Yet, as Strauss and others have shown, Kant's mind betrayed a decided leaning at times to a more mechanical conception of organic forms as related by descent.

Schelling.—In the earlier writings of Schelling, containing the philosophy of identity, existence is represented as a becoming, or process of evolution. Nature and mind (which are the two sides, or polar directions, of the one absolute) are each viewed as an activity advancing by an uninterrupted succession of stages. The side of this process which Schelling worked out most completely is the negative side, that is, nature. Nature is essentially a process of organic self-evolution. It can only be understood by subordinating the mechanical conception to the vital, by conceiving the world as one organism animated by a spiritual principle or intelligence (*Weltseele*). From this point of view the processes of nature from the inorganic up to the most complex of the organic become stages in the self-realization of nature. All organic forms are at bottom but one organization, and the inorganic world shows the same formative activity in various degrees or potences. Schelling conceives of the gradual self-evolution of nature in a succession of higher and higher forms as brought about by a limitation of her infinite productivity, showing itself in a series of points of arrest. The detailed exhibition of the organizing activity of nature in the several processes of the organic and inorganic world rests on a number of fanciful and unscientific ideas. Schelling's theory is a bold attempt to revitalize nature in the light of growing physical and physiological science, and by so doing to comprehend the unity of the world under the idea of one principle of organic development. His highly figurative language might leave us in doubt how far he conceived the higher stages of this evolution of nature as following the lower in time. In the introduction to his work *Von der Weltseele*, however, he argues in favor of the possibility of a transmutation of species in periods incommensurable with ours. The evolution of mind (the positive pole) proceeds by way of three stages,—theoretic, practical, and æsthetical activity. Schelling's later theosophic speculations do not specially concern us here.

Followers of Schelling.—Of the followers of Schelling a word or two must be said. Heinrich Steffens, in his *Anthropologie*, seeks to trace out the origin and history of man in connection with a general theory of the development of the earth, and this again as related to the formation of the solar system. All these processes are regarded as a series of manifestations of a vital principle in higher and higher forms. Oken, again, who carries Schelling's ideas into the region of biological science, seeks to reconstruct the gradual evolution of the material world out of original matter, which is the first immediate appearance of God, or the absolute. This process is an upward one, through the formation of the solar system and of our earth with its inorganic bodies, up to the production of man. The process is essentially a polar linear action, or differentiation from a common centre. By means of this process the bodies of the solar system separate themselves, and the order of cosmic evolution is repeated in that of terrestrial evolution. The organic world (like the world as a whole) arises out of a primitive chaos, namely, the infusorial slime. A somewhat similar working out of Schelling's idea is to be found in Oersted's work entitled *The Soul in Nature* (Eng. trans.). Of later works based on Schelling's doctrine of evolution mention may be made of the volume entitled *Natur und Idee*, by G. F. Carus. According to this writer, existence is nothing but a becoming, and matter is simply the momentary product of the process of becoming, while force is this process constantly revealing itself in these products.

Hegel.—Like Schelling, Hegel conceives the problem of existence as one of becoming. He differs from him with respect to the ultimate motive of that process of gradual evolution which reveals itself alike in nature and in mind. With Hegel the absolute is itself a dialectic process which contains within itself a principle of progress from difference to difference, and from unity to unity. "This process (Mr. Wallace remarks) knows nothing of the distinctions between past and future, because it implies an eternal present." This conception of an immanent spontaneous evolution is applied alike both to nature and to mind and history. Nature to Hegel is the idea in the form of hetereity; and finding itself here it has to remove this exteriority in a progressive evolution towards an existence for itself in life and mind. Nature (says Zeller) is to Hegel a system of gradations, of which one arises necessarily out of the other, and is the proximate truth of that out of which it results. There are three stadia, or moments, in this process of nature—(1) the mechanical moment, or matter devoid of individuality; (2) the physical moment, or matter which has particularized itself in bodies—the solar system; and (3) the organic moment, or organic beings, beginning with the geological organism—or the mineral kingdom, plants, and animals. Yet this process of development is not to be conceived as if one stage is naturally produced out of the other, and not even as if the one followed the other in time. Only spirit has a history; in nature all forms are contemporaneous.[1] Hegel's interpretation of mind and history as a process of evolution has more scientific interest than his conception of nature. His theory of the development of free-will (the objective spirit), which takes its start from Kant's conception of history, with its three stages of legal right, morality as determined by motive and instinctive goodness (*Sittlichkeit*), might almost as well be expressed in terms of a thoroughly naturalistic doctrine of human development. So, too, some of his conceptions respecting the development of art and religion (the absolute spirit) lend themselves to a similar interpretation. Yet while, in its application to history, Hegel's theory of evolution has points of resemblance with those doctrines which seek to explain the world-process as one unbroken progress occurring in time, it constitutes on the whole a theory apart and *sui generis*. It does not conceive of the organic as succeeding on the inorganic, or of conscious life as conditioned in time by lower forms. In this respect it resembles Leibnitz's idea of the world as a development; the idea of evolution is in each case a metaphysical as distinguished from a scientific one.[2] Hegel gives a place in his metaphysical system to the mechanical and the teleological views; yet in his treatment of the world as an evolution the idea of end or purpose is the predominant one.

Of the followers of Hegel who have worked out his peculiar idea of evolution it is hardly necessary to speak. A bare reference may be made to Rosenkranz, who in his work *Hegel's Naturphilosophie*, seeks to develop Hegel's idea of an earth-organism in the light of recent science, recognizing in crystallization the morphological element.

Schopenhauer.—Of the other German philosophers immediately following Kant, there is only one who calls for notice here, namely, Arthur Schopenhauer. This writer, by his conception of the world as will which objectifies itself in a series of gradations from the lowest manifestations of matter up to conscious man, gives a slightly new shape to the evolutional view of Schelling, though he deprives this view of its optimistic character by denying any co-operation of intelligence in the world-process. In truth, Schopenhauer's conception of the world as the activity of a blind force is at bottom a materialistic and mechanical rather than a spiritualistic and teleological theory. Moreover, Schopenhauer's subjective idealism, and his view of time as something illusory, hindered him from viewing this process as a sequence of events in time. Thus he ascribes eternity of existence to species under the form of the "Platonic ideas." As Ludwig Noiré observes,[1] Schopenhauer has no feeling for the problem of the origin of organic beings. He says Lamarck's original animal is something metaphysical, not physical, namely, the will to live. "Every species (according to Schopenhauer) has of its own will, and according to the circumstances under which it would live, determined its form and organization—yet not as something physical in time, but as something metaphysical out of time."

---

[1] Hegel somewhere says that the question of the eternal duration of the world is unanswerable; time as well as space can be predicated of finitudes only.

[2] Mr. Wallace (*Logic of Hegel*, Proleg. pp. 48, 49) speaks of Hegel's system of evolution as having been in a sense the transformation into a philosophic shape of the biological doctrine of evolution as suggested by Treviranus and Lamarck. Yet this relation is by no means obvious.

Von Baer.—Before leaving the German speculation of the first half of the century, a word must be said of Von Baer, who not only reached those ideas of individual and serial development which are at the basis of the modern doctrine of organic evolution, but who recognized in the law of this development the law of the universe as a whole. In his *Entwickelungsgeschichte der Thiere* (p. 264) he distinctly tells us that the law of growing individuality is "the fundamental thought which goes through all forms and degrees of animal development and all single relations. It is the same thought which collected in the cosmic space the divided masses into spheres, and combined these to solar systems; the same which caused the weather-beaten dust on the surface of our metallic planet to spring forth into living forms." Von Baer thus prepared the way for Mr. Spencer's generalization of the law of organic evolution as the law of all evolution.

Early Half of the Century—English Writers.—We may here conveniently break off our review of German evolutionists, returning to the writers of the latter part of the century presently. The thinkers outside Germany who in the first half of the century contributed elements to the growth of the idea of evolution are too unimportant to detain us here. In the English philosophy of this period questions of cosmology play a very inconsiderable part. The development of the analytical psychology, especially by the two Mills, may be referred to. Also an allusion may be made to the discussions respecting the nature of cause. Among these Sir W. Hamilton's definition of cause (*Lectures on Metaphysics*, ii. 377) is specially interesting as appearing to tell against the production of mind out of matter.

French Writers—Comte.—In France during this period the name of Auguste Comte is the only one that need arrest our attention. Comte's principles of positivism, which restricted all inquiry to phenomena and their laws, are said by his recent disciples to exclude all consideration of the ultimate origin of the universe, as well as of organic life. Yet though Comte did not contribute to a theory of cosmic organic evolution, he helped to lay the foundations of a scientific conception of human history as a natural process of development determined by general laws of human nature together with the accumulating influences of the past. Comte does not recognize that this process is aided by any increase of innate capacity; on the contrary, progress is to him the unfolding of fundamental faculties of human nature which always pre-existed in a latent condition; yet he may perhaps be said to have prepared the way for the new conception of human progress by his inclusion of mental laws under biology.

Italian Writers.—In Italy during this period there meet us one or two thinkers who concern themselves with the interpretation of the world-process. Ant. Rosmini follows Campanella in endowing chemical atoms with sensibility and life, and he bases the hierarchy of beings in the universe on the different degrees of this sensibility. At the same time he follows Bruno in speaking of the totality of the world as an organism endowed with a soul which individualizes itself in the innumerable existences of the universe. Spontaneous generation is to Rosmini a necessary consequence of his theory of a universal life. Other Italian writers adopt Hegel's notion of the world as a self-evolution of the idea. Of these it is enough to mention Terensio Mamiani, who gives an optimistic turn to his conception of evolution by viewing it as a progressive union of the finite with the infinite. Mamiani argues against Darwin, and holds that all specific forms are fixed for all time.

Modern Doctrine of Evolution.—We now approach the period in which the modern doctrine of evolution in its narrow sense has originated. This doctrine is essentially a product of scientific research and speculation. It is a necessary outcome of the rapid advance of the physical sciences. Its final philosophic form cannot yet be said to be fixed. It may be defined as a natural history of the cosmos including organic beings, expressed in physical terms as a mechanical process. In this record the cosmic system appears as a natural product of elementary matter and its laws. The various grades of life on our planet are the natural consequences of certain physical processes involved in the gradual transformations of the earth. Conscious life is viewed as conditioned by physical (organic and more especially nervous) processes, and as evolving itself in close correlation with organic evolution. Finally, human development, as exhibited in historical and prehistorical records, is regarded as the highest and most complex result of organic and physical evolution. This modern doctrine of evolution is but an expansion and completion of those physical theories which opened the history of speculation. It differs from them in being grounded on exact and verified research. As such, moreover, it is a much more limited theory of evolution than the ancient. It does not concern itself (as yet at least) about the question of the infinitude of worlds in space and in time. It is content to explain the origin and course of development of the world, the solar or, at most, the sidereal system which falls under our own observation. It would be difficult to say what branches of science had done most towards the establishment of this doctrine. We must content ourselves by referring to the progress of physical (including chemical) theory, which has led to the great generalization of the conservation of energy; to the discovery of the fundamental chemical identity of the matter of our planet and of other celestial bodies, and of the chemical relations of organic and inorganic bodies; to the advance of astronomical speculation respecting the origin of the solar system, etc.; to the growth of the new science of geology which has necessitated the conception of vast and unimaginable periods of time in the past history of our globe, and to the rapid march of the biological sciences which has made us familiar with the simplest types and elements of organism; finally, to the recent development of the science of anthropology (including comparative psychology, philology, etc.), and to the vast extension and improvement of all branches of historical study.

English Writers—Darwin.—The honor of working out this theory of evolution on a substantial basis of fact belongs to England. Of the writers who have achieved this result Mr. Darwin deserves the first notice. Though modestly confining himself to the problem of accounting for the evolution of the higher organic forms out of the lower, Mr. Darwin has done much to further the idea of a gradual evolution of the physical world. The philosophic significance of the hypothesis of natural selection, especially associated with Mr. Darwin, is due, as Professor Helmholtz points out, to the fact that it introduces a strictly mechanical conception in order to account for those intricate arrangements known as organic adaptations which had before been conceived only in a teleological manner. By viewing adaptations as conditions of self-preservation, Mr. Darwin is able to explain how it is that the seemingly purposeful abounds in organic nature. In so doing he has done much to eliminate the teleological method from biology. It is true that, in his conception of seemingly spontaneous variations and of correlations of growth, he leaves room for the old manner of viewing organic development as controlled by some internal organizing principle. Yet his theory, as a whole, is clearly a heavy blow to the teleological method. Again, Mr. Darwin has greatly extended the scope of mechanical interpretation, by making intelligible apart from the co-operation of intelligent purpose, the genesis of the organic world as a harmonious system of distinct groups, a unity in variety, having certain well-marked typical affinities. How greatly this arrangement has helped to support the idea of an ideal plan, we have had occasion to observe. Mr. Darwin in his doctrine of the organic world as a survival refers this appearance of systematic plan to perfectly natural causes, and in so doing he gives new meaning to the ancient theory that the harmony of the world arises out of discord. Once more, Mr. Darwin's hypothesis is of wide philosophic interest, since it helps to support the idea of a perfect gradation in the progress of things. The variations which he postulates are slight, if not infinitesimal, and only effect a sensible functional or morphological change after they have been frequently repeated and accumulated by heredity.

---

[1] *Der monistische Gedanke*, p. 238 *sq.*

Mr. Darwin's later work, in which he applies his theory of the origin of species to man, is a valuable contribution to a naturalistic conception of human development. The mind of man in its lowest stages of development is here brought into close juxtaposition to the animal mind, and the upward progress of man is viewed as effected by natural causes, chief among which is the action of natural selection. Mr. Darwin does not inquire into the exact way in which the mental and the bodily are connected. He simply assumes that, just as the bodily organism is capable of varying in an indefinite number of ways, so may the mental faculties vary indefinitely in correspondence with certain physical changes. In this way he seeks to account for all the higher mental powers, as the use of language and reason, the sentiment of beauty and conscience.

Finally, Mr. Darwin seeks to give a practical and ethical turn to his doctrine. He appears to make the end of evolution the conscious end of man's action, since he defines the general good as "the rearing of the greatest number of individuals in full health and vigor, and with all their faculties perfect under the conditions to which they are subject." Further, in his view of the future of the race, Mr. Darwin leans to the idea that the natural process which has effected man's first progress must continue to be an important factor in evolution, and that, consequently, it is not well to check the scope of this process by undue restraints of population, and a charitable preservation of the incompetent.

A. R. Wallace.—Mr. A. R. Wallace, who shares with Mr. Darwin the honor of establishing the doctrine of natural selection, differs from the latter in setting much narrower limits to the action of this cause in the mental as well as the physical domain. Thus he would mark off the human faculty of making abstractions, such as space and time, as powers which could not have been evolved in this way. Mr. Wallace leans to the teleological idea of some superior principle which has guided man in his upward path, as well as controlled the whole process of organic evolution. This law is connected with the absolute origin of life and organization.

Herbert Spencer.—The thinker who has done more than any one else to elaborate a consistent philosophy of evolution on a scientific basis is Mr. Herbert Spencer. First of all he seeks to give greater precision to the conception of this universal process. Evolution is a change from the homogeneous to the heterogeneous, from the indefinite or undetermined to the definite or determined, from the incoherent to the coherent. Again, Mr. Spencer seeks to show that the causes of evolution are involved in the ultimate laws of matter, force, and motion, among which he gives great prominence to the modern doctrine of the conservation of energy. Thus the rationale of the process shapes itself to Mr. Spencer as a distinctly mechanical problem. He sets out with the assumption of a limited mass of homogeneous matter acted upon by incident forces, and seeks to show how, by help of two laws,—namely, the instability of the homogeneous, and the multiplication of the effects of any such incident force,—the process known as evolution is brought about. This process is illustrated in the genesis of the solar system,[1] for the explanation of which Mr. Spencer makes use of the nebular hypothesis, in the formation of our planet, as well as the development of organic and mental life. Mr. Spencer, does not, however, conceive of this process of evolution as unlimited in time. As in the development of the individual organism, so in that of organic beings as a whole, of the earth, and of the solar system, there is a conflict between the forces of which the action is integrating or consolidating and those of which the action is disintegrating. The process of evolution always tends to an equilibration between these conflicting forces and ultimately to a dissolution of the products of evolution. Thus the solar system is a moving equilibrium which is destined to be finally dissipated into the attenuated matter out of which it arose. Mr. Spencer thus approaches the earliest theories of cosmic evolution when he tells us (*First Principles*, p. 482) that vast periods in which the forces of attraction prevail over those of repulsion, alternate with other vast periods in which the reverse relation holds. The mechanical theory of evolution thus laid down in the *First Principles* is applied in Mr. Spencer's later works to the explanation of organic, mental, and social evolution. The full explanation of the processes of inorganic evolution finds no place in the writer's system. Mr. Spencer seeks, in the *Principles of Biology*, to conceive of organic bodies and their actions in mechanical terms. Life is regarded as essentially a correspondence of internal actions in the organism to external actions proceeding from the environment, and the object of Mr. Spencer's volumes is to explain on mechanical principles the growth of this correspondence from the lowest to the highest. He excludes all consideration of the question how life first arose, though it is clear that he regards the lowest forms of life as continuous in their essential nature with sub-vital processes. It is in the later volumes, dealing with mental and social evolution, that Mr. Spencer's exposition becomes most interesting to the student of philosophy. In the *Principles of Psychology*, he seeks to deal with mind as an aspect or correlate of life which begins to manifest itself when the process of adjustment to environment, in which all life consists, reaches a certain degree of complexity. Mr. Spencer indulges in no hypothesis respecting the universal co-existence of sentience with matter and force. He thinks we must accept the distinctions which common-sense has established, and so limit feeling or consciousness to organic beings endowed with a nervous system. Thus, just as he does not seek to explain the first appearance of life as a whole, so he does not seek to explain the first dawn of mental life. Mr. Spencer's unit of consciousness is the blurred undetermined feeling which answers to a single nervous pulsation or shock. Assuming this he seeks to trace the gradual evolution of consciousness. Sensations arise by a number of rapid successions of such elementary feelings variously combined, and all more composite states of mind arise by a similar process of combination of these feelings. Thus mental evolution is a progressive composition of units of feeling in more and more complex forms, and united by more complex relations. Mr. Spencer's conception of mind thus excludes all fundamental distinctions of faculty. Instinct, memory, reason, the emotions and volitions, alike develop themselves in divergent directions out of a common elementary process. They are, moreover, all related to one and the same biological process, being incidental accompaniments of the actions by which the organism responds and adjusts itself to the forces of its environment. According as these actions are more complex, and consequently less immediate, the mental actions which accompany them vary in character from reflex action up to deliberate volition, from the most simple presentative feeling or sensation up to the most complex representative and re-representative feeling or emotion. It would be impossible to point to all the applications which Mr. Spencer has made of his principle of evolution to the questions of pyschology. We may just mention among other points of interest his attempt to explain the innate intuitions of space, moral right, etc., as mental dispositions handed down from progenitors and embodying the uniform experience of many generations, his ingenious endeavor to account for the coincidence between pleasures and pains and actions beneficial and injurious to the organism, and his conception of the æsthetic interest as a growth out of the play-impulse, which is the tendency of activities that have become developed beyond the immediate needs of existence to vent themselves.

Mr. Spencer's elaboration of the subject of social evolution has not been carried far enough for us to understand the full bearing of his ideas. Yet the fundamental conceptions are given us. The writer regards society, after the analogy of an individual organism, as possessing a number of various structures or organs and functions, and as tending to evolve itself by a series of adjustments to its environment, physical and social. All ideas and institutions display this process of evolution no less than societies as wholes. History is to our author essentially the record of this social evolution. It is to be observed that Mr. Spencer attributes to society a certain spontaneous tendency to evolution apart from natural selection. He looks on progress as a gradual process of self-adaptation of man to the conditions of his environment, and anticipates an age when this adjustment will be complete and human happiness perfect. In this respect Mr. Spencer's conception of man's history and destiny wears an optimistic tinge when compared with that very vaguely shadowed forth by Mr. Darwin.

To Mr. Spencer, as to Mr. Darwin, the doctrine of evolution seems to supply the end of conduct. He conceives of morality as essentially an observance of the laws of life, the individual and the collective. At the same time, since Mr. Spencer regards the moral sense as a growth out of feelings of pleasure and pain (racial experiences), closely identifies the ends of life and happiness, and distinctly teaches that social evolution or progress makes for an increase of happiness, his ethical doctrine does not materially differ from that of utilitarianism.

---

[1] The writer suggests that the whole sidereal system may be the result of a similar process.

So far we have said nothing respecting the metaphysical basis which Mr. Spencer seeks to give to his doctrine of evolution. It is generally agreed that this does not really belong to his doctrine of evolution itself. Mr. Spencer is a thorough-going realist. From his general scheme of evolution one would be prepared to find him avowing himself a materalist. Yet he seeks to avoid this conclusion by saying that it is one unknowable reality which manifests itself alike in the material and in the mental domain. At the same time, this unknowable is commonly spoken of as force, and in many places seems to be identified with material force. Mr. Spencer makes little use of his metaphysical conception in accounting for the evolution of things. He tells us neither why the unknowable should manifest itself in time at all, nor why it should appear as a material world before it appears under the form of mind or consciousness. Indeed Mr. Spencer's doctrine of evolution cannot be said to have received from its author an adequate metaphysical interpretation. The idea of the unknowable hardly suffices to give to his system an intelligible monistic basis. In truth, this system seems in its essence to be dualistic rather than monistic.

Metaphysical Interpretation—Professor Clifford.—Of the very few who have dealt with the metaphysical interpretation of the scientific doctrine of evolution, Professor Clifford deserves special notice. In an essay entitled "On things in themselves," published in *Mind* (No. 9), as well as in other and earlier papers, Mr. Clifford, starting from the basis of empirical idealism which asserts that material objects are nothing but states of consciousness, argues that the reality answering to them is in all cases something mental. Thus all existence—including what we call minds as well as bodies—consists in aggregates of elementary "mind stuff," the elements themselves corresponding to Mr. Spencer's units of feeling. The writer expressly argues that his idea of a continuity of mental existence throughout the physical (phenomenal) world is the direct consequence of the doctrine of evolution. This theory is curious as providing a monistic and quasi-spiritualistic conception of evolution, which is at the same time a mechanical one.

Problems of Organic Evolution—G. H. Lewes.—Among the writers who have worked on the lines laid down by our two great evolutionists, a high place must be given to Mr. G. H. Lewes, who in his biological and psychological writings, and more especially the *Problems of Life and Mind*, adopts a view of the relations of mind and life or organization closely resembling in its essentials that of Mr. Spencer. To Mr. Lewes consciousness is but a more complex form of mental life which is correlated with the actions of all the nervous centres, its lowest form being sentience. He appears to look on mind in all its grades as but the other side or face of the bodily processes which it accompanies. Yet he has not so far made use of this monistic conception in explaining the gradual evolution of conscious mental life. Indeed, though Mr. Lewes's writings are pervaded with the idea of organic evolution, his discussion of the nature and laws of organism in his last volume, *The Physical Basis of Mind*, might seem ever and again, by its sharp separation of organic and inorganic (mechanical) processes, to tell against the supposition of an evolution of life out of inorganic matter.

J. J. Murphy.—The question of the genesis of life and mind receives a peculiar treatment in Mr. J. J. Murphy's *Habit and Intelligence*. In this work the teachings of the evolutionists are largely accepted, while an attempt is made to reconcile these with a teleological view of nature. The process of inorganic and of organic nature is each recognized as one of evolution; but while the former is viewed as the result of mechanical principles, the latter is said to imply an intelligent or formative principle as well. Mechanical principles do indeed operate in organisms, this is the region of habit; but over and above this, vital processes involve a controlling intelligence. The author adopts the hypothesis that the Creator endowed vitalized matter at the first with intelligence under the guidance of which it organizes itself. Evolution is largely the result of this vital intelligent principle, only a small part being attributable to mechanical causes, such as natural selection.

Evolution and Psychology.—The speculations of Mr. Darwin and Mr. Spencer have had a powerful influence on recent English psychology, which promises to become comparative, not only in the sense of including a comparison of ethnological mental characteristics, but also in the wider sense of bringing human intelligence into relation to that of the lower animals. Among writers who have labored in this construction of a theory of mental evolution, mention must be made of the late Mr. D. Spalding.[1] Again, Mr. Chauncey Wright, in his remarkable essay *The Evolution of Self-Consciousness* (printed in a collection of his works), made a brilliant attempt to represent man's highest mental operations as evolved out of simple processes common to man and the lower animals. The influence of evolutional ideas is further traceable in the latest work of Mr. A. Bain (*Emotions and Will*, 3d edition), and in the works of Dr. Maudsley and other living psychologists. The relation of the doctrine of evolution to psychology is handled in an essay by Mr. J. Sully (*Sensation and Intuition*, ch. i.).

Anthropology.—The application of the doctrine of evolution to the question of man's origin and development has engaged the attention of a number of writers. In a sense all recent anthropologists and historians of culture may be said to have worked in this direction. Special attention must, however, be called to those writers who have sought directly to apply the fundamental ideas of evolution to these problems. Mr. Bagehot's *Physics and Politics* is remarkable as illustrating the employment of the doctrine of natural selection in order to explain certain aspects of political progress. Still more important is the contribution made by Mr. Fiske, in his *Cosmic Philosophy*, to the theory of man's origin and development. Mr. Fiske's work is a full exposition of Mr. Spencer's doctrine of evolution. In addition to this it contains interesting speculations respecting the steps by which man's distinguishing intelligence and sociality were first acquired and afterwards developed.

Relation to Ethics.—The application of the doctrine of evolution to our ethical and religious ideas has engaged a number of writers. In Mr. A. Barratt's *Physical Ethics* the development of man's moral sense out of feelings of pleasure and pain is traced in connection with his organic and social evolution on which it is said to depend. By conceiving of all matter as endowed with sensibility (pleasure and pain), Mr. Barratt is able to connect man's moral evolution with the whole process of organic and of cosmic evolution. The idea of a natural growth of the moral sense out of simpler impulses and instincts may also be frequently found in contemporary English literature. On the other hand, this consequence of the evolution theory has been strenuously opposed in the interests of a thorough-going intuitive ethics as, for example, by Mr. St. George Mivart, in his work, *The Genesis of Species*, and by Mr. R. H. Hutton.[2]

Again the question has been discussed whether the doctrine of evolution contributes towards the determination of the end or standard of morals. Mr. Sidgwick has shown that it cannot well do this merely by proving how the moral sense has arisen. It is easy, however, to look upon the natural process as a tendency towards an end, and to conceive of our conscious actions as being bound by this tendency, so that the highest end of our existence must be to co-operate with the natural forces. This idea pervades a good deal of contemporary literature. It appears with special distinctness in the writings of Professor Clifford[3] and Mr. F. Pollock[4] and in the able work of Miss Simcox on *Natural Law*. On the other hand, Mr. H. Sidgwick[5] has made an elaborate study of the bearings of evolution on the ethical end, and reduces these to insignificant proportions. This writer criticises Mr. Darwin's definition of the general good, and argues that the idea of a mere quantity of life is inadequate to supply a definite end of conduct. Nevertheless life (ζῇν) is the prime condition of well-being (εὖ ζῇν), and so far the evolutionist is right in making life a secondary aim. The differentia of well-being, however, requires further interpretation, which can only be supplied by the utilitarian principle. At the same time the doctrine of evolution guides us in the pursuit of this ultimate end, in so far as increase of happiness accompanies organic progress, or elevation in the scale of existence. Mr. Sidgwick further points out how little the doctrine of evolution assists the utilitarian in dealing with social and political problems.

[5] See an article headed "The Theory of Evolution in its relation to Practice," in *Mind*, No. 1; cf. *Methods of Ethics*, 2d edition, pp. 69, 70 *et passim.*

Relation to Religion.—The bearing of the doctrine of evolution on religion has formed the theme of a host of minor writings. On the whole, Mr. Darwin's doctrine has been said (as it is by the author himself), not only to be compatible with the idea of an original creation of the world, but to supply a higher conception of the divine attributes than the hypothesis of special creations; on the other hand, Mr. Spencer's doctrine, distinctly excluding as it does the idea of creative activity, has called forth strong opposition from a number of theological writers, among whom the most powerful is certainly Professor Martineau.[1] In connection with the subject of the relation of the evolution doctrine to religious ideas, it is worthy of remark that this doctrine appears to be serving as the starting-point for a new quasi-religious conception of nature. The idea of the cosmos and its forces as the author and source of our being easily lends itself to a kind of pantheistic sentiment towards nature. In Mr. Spencer's own writings it is the unknowable force ever sustaining the evolving worlds which is said to excite this emotion. In the work of Miss Simcox already referred to, and the occasional papers of Professor Clifford,[2] it is rather visible nature itself which is thus elevated into a religious object.

Recent French Writers.—The French thought of the latter part of the century offers us but little in the way of a discussion of the problems with which evolution has to do. The activity of biological speculation appears to have influenced but a few philosophic minds. Naturalists have of course discussed the doctrine of evolution, and one of these, E. Quinet, in his work *La Creation*, seeks to apply Mr. Darwin's theory to problems of art and morality. Thus the ideal of art should, he thinks, be based on the doctrine of evolution, and be "the presentment of superior forms which slumber still in the bosom of actual things," or the embodiment of "the possible development of the human type in the progress of nature and man." So the ideas of duty and virtue are to be based on this doctrine. Man is the only animal which can retrograde, and evil is retrogression in the path laid down by nature. It is an anachronism, or a revolt of man against himself. Among philosophic writers proper, the first place must be given to M. Th. Ribot, who, in his sympathetic exposition of Mr. Spencer's doctrine of evolution in his *Recent English Psychology*, and in his interesting psychological study *On Heredity*, shows himself to be deeply pervaded with the new ideas, more especially in their bearing on mental phenomena. M. Ribot regards mental evolution as depending on material, but adds that the recognition of this connection between the two domains of phenomena is compatible with idealism no less than with materialism. He would eliminate the conception of progress as a subjective one, and says that the idea of historical progress must be taken up into that of an objective cosmic process. M. Ribot makes many interesting applications of his law of mental heredity, which he rightly regards as a factor in mental evolution; as, for example, when he speaks of free-will as expressing the fixed personal factor in conduct,—namely, the inherited character. Of other philosophic writers who have been affected by the English doctrine of evolution, it is sufficient to name the late Léon Dumont, who was one of the first in France to apply the ideas of Mr. Darwin and Mr. Spencer to problems of psychology; and Professor A. Espinas, who in his work *Des Sociétés Animales* aims at furthering the theory of man's psychical derivation from lower types of mind. A writer who appears to be in a less distinct manner influenced by the idea of evolution is M. Taine, in whose psychological and historical studies the indirect effect of a study of English evolutionists is traceable. On the other hand, the older and teleological view of the world has not wanted its defenders. The most signal supporter of this direction, in the face of the doctrine of evolution, is M. Paul Janet, who, in his earlier work *Le Materialisme Contemporain*, and still more in his recent publication *Les Causes Finales*, draws a sharp line between the regions of the organic and the inorganic, and maintains that the complex arrangements of the latter are only explicable by means of teleological conceptions.

Recent German Writers—Materialists.—In Germany the recent progress of speculation, since the time of the great systems has exhibited a decided bent towards the problems which group themselves around the doctrine of evolution. First of all the efforts of the materialists directly tended to the formation of a consistent doctrine of cosmic evolution. Their earlier writings appeared just before the epoch-making publication of Mr. Darwin, but the ideas of the latter have been incorporated in their later publications. In Moleschott's *Der Krieslauf des Lebens* the whole order of things is conceived as a continual flux and exchange of material elements, which accounts for all psychic life no less than for bodily life, and of which man, equally with the lower animals, is a temporary product. L. Büchner has sought, in his work on *Man* and his *Six Lectures on the Darwinian Theory* to defend the new doctrine of organic evolution as a necessary factor in the materialistic conception of the world. The latter work connects Darwinism with the whole history of materialism. The former is a somewhat feeble attempt to attach man's ideal aims in the future to the evolutionist's conception of his past history. The writer appears to think that something equivalent to the process of natural selection is to effect man's future progress, but the idea is not presented with any definiteness or precision.

Combination of Mechanical and Teleological View of Evolution.—After the materialists we come to a number of writers, who, under the influence of advancing physical and physiological science, have sought to construct a mechanical conception of the order of the world. Some of these have contented themselves with sketching a natural history of the cosmos, others have connected their mechanical conception with peculiar philosophical ideas.

Czolbe.—A curious combination of the mechanical and teleological conceptions of the world is to be met with in the system of Czolbe. In his first works, *Die neue Darstellung des Sensualismus* and *Die Entstehung des Selbst-Bewusstsein's* Czolbe regards the world as a product of elementary matter and organic forms, both of which are eternal. According to this view, sensation and consciousness are products of particular combinations of movements (circular). To these two original principles he adds, later on, feelings and sensations themselves, which exist in a latent state throughout space, and form a kind of world-soul. Still later, he finds the substantial support of atoms and sensations alike in space, in which feelings are located no less than the material elements. To Czolbe our visible world, together with conscious minds, is thus a mosaic formed out of these elements, which group themselves according to mechanical laws in bodies and conscious minds. He thus adopts a theory of natural evolution which evades the difficulty of explaining the organic as a product of the inorganic, and mind as a product of matter. But he only achieves this by assuming the eternity of all organic forms, and by conceiving of the elementary sensations as themselves spatial or "extensional." Though the mechanical view of the world-order is most prominent in Czolbe, he combines with this a teleological and optimistic view, according to which all things make for the greatest possible perfection of conditioned happiness in every sentient creature.

G. T. Fechner.—Another writer who combines the mechanical view of the world with a curious metaphysical system is G. T. Fechner. Passing by his earlier works, in which he develops his idea of the world as a gradation of souls (including those of plants, an earth-spirit, etc.) we may best turn to his later work *Einige Ideen zur Schöpsfungs- und Entwickelungs-Geschichte der Organismen.* Fechner takes a thoroughly mechanical view of the difference between organic and inorganic matter. But by help of this very difference he seeks to prove that the latter is a product of the former, and not conversely. The great law which determines the evolution of the world is the tendency to greater and greater stability, which law at once supplies a mechanical and a teleological conception of the universe. Organic bodies differ from inorganic in that their molecules are in a less stable condition than those of the latter. Hence we must suppose that the original source of the material world is an organism, namely, a primitive "cosmorganic" condition of our earth. This primitive matter has gradually differentiated itself into the regions of the organic and the inorganic, and the former again into the animal and vegetable kingdoms. Consciousness was breathed into the cosmorganic matter by the Creator, and so pressed out, as though from the bellows of an organ, into all living creatures. This process of evolution is directed towards an end, namely, the greatest possible degree of mutual adaptation of parts, or the most stable condition; and conscious action is but the subjective side of this tendency.[1]

---

[1] See the pamphlet *Modern Materialism*, in which Professor Tyndall's version of evolution is severely criticised; also an article "The Place of Mind in Nature and Intuition in Man," *Contemp. Rev.*, vol. xix. p. 606 *sq.*

[2] See especially an article on "Cosmic Emotion," in the *Nineteenth Century*, October, 1877.

Lotze.—The mechanical view of the world, as wrought out by modern science, is fully recognized and yet surmounted in the cosmological doctrine put forth by Hermann Lotze in his *Mikrokosmus.* Lotze defends the mechanical method as applicable to all departments of phenomena, and insists on this way of viewing organic processes. At the same time he holds that the mechanical interpretation of nature is limited at every point. The inadequacy of this view may be seen in the attempt to apply it to the question of the genesis of the world and its order. On the one hand, Lotze accepts the teachings of modern speculation respecting the evolution of the solar system, the genesis of the organic out of the inorganic, the continuity of man with the lower animal world; and his exposition and defence of this idea of evolution as the result of mechanical laws is extremely able and interesting. Again, Lotze seeks to bridge over the gulf between material and spiritual evolution by bringing human development into close relation to the processes of nature as a whole. Yet, while thus doing justice to the mechanical conception of the gradual genesis of the world, Lotze strenuously affirms the limitations of this kind of explanation. In the first place, he maintains that the mechanical processes themselves cannot be understood except by help of ideas respecting the real internal nature of the elements concerned. This nature he describes as life, and thus he endows all parts of matter with feeling (though he distinctly rejects Czolbe's idea of a world-soul which includes these feelings). In this internal activity Lotze finds a teleological element, viz., a striving towards self-preservation and development. This idea he seeks to blend with that of mechanical relations among the elements, so as to make the whole upward process of physical evolution the product of purposeful impulses. Thus the first genesis of organisms is represented as a combination of elements (accidentally meeting), through which there is effected a summation of the separate ends of the elements, to a purposeful equilibrium of a composite whole.[2] This may be called the first stage of his teleology. In addition to this, Lotze looks at the world-process as a gradual unfolding of a creative spiritual principle, which he sometimes figuratively describes as the world-soul, more commonly, however, as the infinite substance. This assumption, he says, is necessitated by the very process of cosmic evolution, the absolute beginning and end of which we are wholly unable to conjecture. However far back the evolutionist may go he always has to assume some definite arrangement of parts,—some general laws of action of which he can give no account. The conception of the atomists, that in the beginning of things there was an indefinite number of possibilities, is unthinkable, and the modern doctrine of evolution, by conceiving of the existing world as a survival of certain forms from among many others actually produced, but lacking in the conditions of stability, plainly makes no such absurd supposition. Hence, there must always be a certain order to be accounted for, and science is wholly inadequate to effect this explanation. This conducts to a teleological view of the world-process, as directed by mind towards some end which we cannot distinctly recognize. Lotze's criticisms of previous attempts to formulate the end of the world-process are not the least valuable part of his discussion of the problems of evolution. He shows that neither the notion of a progressive effort towards the highest unfolding of mental life, nor that of an impulse towards the greatest variety of manifestations of one and the same fundamental form, adequately represents the order of organic forms. Here Lotze shows again a due recognition of the mechanical aspect of the world-process, and argues that the evolution of the organic world is no immediate consequence of the self-evolving ideas, but only the form in which the commands of these ideas are capable of being realized on our earth,—that is to say, with our terrestrial conditions. A somewhat similar view of cosmic and organic evolution, as at once a mechanical and a teleological process, is to be found in Ulrici's *Gott und die Natur.*

Mechanical Doctrines of Evolution.—Over against these attempts to carry up a mechanical conception of evolution into a teleological must be set a number of works which content themselves, in the spirit of positive science, with expounding a doctrine of evolution on a strictly mechanical basis. Of these we may first mention C. Radenhausen (Isis), who, in his interesting work *Der Mensch und die Welt,* expounds the idea of a gradual evolution of the solar system, the earth, and organic life. In the growth of the individual man the past evolution of the world is represented. A temperate statement of the doctrine of modern evolution is to be found in Dr. Ch. Wiener's volume *Die Grundzüge der Weltordnung.* The problems of the origin of organic life and of the genesis of the nervous system are both said to be as yet insoluble. With this may be compared another interesting presentation of the doctrine of evolution,—namely, H. J. Klein's *Entwickelungsgeschichte des Kosmos.* The mechanical causes of evolution are clearly set forth in a work of the Herbartian C. S. Cornelius, *Ueber die Entstehung der Welt.* Cornelius argues against Czolbe's hypothesis of the past eternity of organic life. Organisms first arose under some quite special physical conditions. A very curious feature in this volume is the criticism of Mr. Darwin's doctrine of descent, which is said to involve mystical ideas, etc.

Lange.—Among later works touching on the problems of evolution the *History of Materialism* of Lange deserves mention here. Lange accepts the modern hypothesis of evolution, and justifies the mechanical conception of its various stages. It is true that in his criticism of Mr. Darwin's theory he assumes some internal formative principle (as held to by Nägeli and Kölliker) as supplementary to the factor of utility emphasized by Mr. Darwin. Yet he does not appear to regard this process as other than a mode of mechanical action. Lange's greatest difficulty in view of a consistent materialistic doctrine of evolution is to explain the genesis of conscious life. The difficulty of the atomistic theory, even when we add a rudimentary sensibility to the elements, is to determine "where and how the transition is affected from the manifoldness of the collisions of the atoms to the unity of sensation." Lange supplements his mechanical view of the world by the Kantian conception of the adaptation of the world by reason of its generalities or uniformities to our intelligence. He argues, with Lotze, that in seeking to frame a theory of physical evolution we must always assume, over and above the eternal atoms, a special initial arrangement of these, without which the order of events would be inconceivable. This modest kind of teleology (he says) is not only not opposed to Mr. Darwin's doctrine; it is its necessary pre-supposition. "The formal purposefulness of the world is nothing else than its adaptation to our understanding." Lange seems further disposed to accept Kant's theory of organism as manifesting objective purpose, though he will not allow that this explains anything, all explanations being by way of the principle of mechanical causation.

Noiré.—In Ludwig Noiré we have a writer who accepts all the teaching of scientific evolutionists, and at the same time seeks to give to the doctrine a metaphysical and monistic interpretation. In his two volumes *Die Welt als Entwickelung des Geistes* and *Der Monistische Gedanke,* Noiré assumes the existence of elementary atoms or "monads" endowed with the two-fold properties of motion and sensation. Time and space are not simply forms of intuition, but forms of appearance (*Erscheinungsformen*) of these fundamental properties. The process of evolution from the simple to the complex has its ground in the latter property, sensation, which gives its direction to motion (which latter is unchangeable in amount), and which involves a tendency or impulse to further differentiation. The purposefulness of the process of evolution is due to its being the work of a mental principle (sensation). The formation of inorganic bodies is the preliminary step in the process, and involves an obscure mode of consciousness. The genesis of consciousness is said to be effected by means of a certain mode of collision among the atoms, though this point is not made very clear. Noiré's doctrine of evolution appears to waver somewhat between a mechanical theory (atoms endowed with sensibility, but acting according to strictly mechanical laws) and a distinctly spiritualistic and teleological doctrine, such as that of Schelling and Hartmann.

---

[1] In a new edition of his work Fechner avows himself a convert to Mr. Darwin's theory of organic descent.

[2] Lotze does not express himself very clearly with respect to the question of the first genesis of mind. In the *Mikrokosmus* (ii. p. 33) he appears to find the "sparks" of mental life in the atoms which he here conceives of after the manner of Leibnitz's monads. In another place, however (*Medicinische Psychologie*, pp. 164, 165), Lotze tells us that mind is the direct product of the original creative activity, which is stimulated to create by the stimulus involved in the formation of the physical germ.

Hartmann.—The writings of E. von Hartmann have a special interest, as illustrating how Mr. Darwin's doctrine of organic development is regarded from the point of view of a thorough-going metaphysical teleology. To Hartmann the world is a manifestation in time—which is real as applying to the activities of this principle—of an ontological principle, styled the unconscious, which is at once will and intelligence. The process of evolution, from the simplest material operations up to conscious human actions, depends on the progressive domination of will, which is the blind force, and answers to the mechanical aspect of the world, by intelligence, which gives to this force form and direction, and answers to the logical and teleological aspect of the world. The end of the process for which this unconscious makes is not, as Hegel says, self-consciousness, but non-existence, to which consciousness is the immediate pre-condition. Hartmann has devoted a separate volume to Mr. Darwin's theory (*Wahrheit und Irrthum im Darwinismus*), in which he shows himself disposed to accept the principle of natural selection as the mechanical means which the unconscious makes use of in order to effect a certain amount of the upward organic progress towards which it strives.

Influence of Darwinism in Germany.—We will close the sketch of the recent German discussion of evolution-problems, and so our historical review as a whole, by a brief reference to the philosophic and quasi-philosophic literature which has sprung up in Germany under the direct influence of Mr. Darwin's doctrine. It is not a little curious that, of the two great English evolutionists, the one who has most stimulated German philosophical thought is the writer who has confined himself to questions of natural science, while the writer who has built up the idea of organic descent into a complete cosmological theory is only now beginning to be known in that country.

(*a*) *Darwinism and Methodology.*—First of all, then, a bare allusion must be made to certain criticisms of Mr. Darwin's biological hypothesis as legitimate instruments of a sound natural philosophy. It may surprise some English readers to learn that the doctrine of the descent of species by natural selection has been denounced in Germany as partaking of the vices of a spurious and teleological natural philosophy. The writer who has taken most pains to show up the philosophic unsoundness of Mr. Darwin's procedure is A. Wigand (*Der Darwinismus und die Naturforschung Newton's und Cuvier's*, see especially vol. ii.).

(*b*) *Darwinism and Cosmology.*—Turning now to the influences of Darwinism on German thought, we may best begin with the more circumscribed branches of speculation. Physical speculation in Germany is being slowly affected by Mr. Darwin's theory. A curious example of this is to be met with in a little work by Dr. Karl du Prel, entitled *Der Kampf ums Dasein am Himmel.* This work is of real philosophic interest as illustrating how Mr. Darwin's way of conceiving self-preservation, as the effect of natural superiority in respect of adaptability to the conditions of existence, may be extended beyond the organic world to the cosmos as a whole. Du Prel regards the cosmic bodies as analogous to competing organisms, space standing for the means of existence for which they struggle, and the force of attraction and the fitness of the body's movement in relation to those of other bodies representing organic efficiency. Those bodies which have these advantages survive, whereas those which lack them are extinguished either by being dissipated or fused with other bodies.

(*c*) *Darwinism and Anthropology.*—Passing by the biological speculations respecting the ultimate origin of living forms to which Darwinism has given rise, we pass to those aspects of anthropology which have a peculiar philosophic interest. In a sense it may be said that Mr. Darwin's speculations, especially as carried out by himself in his *Descent of Man*, have powerfully influenced the whole of recent anthropological speculation; for writers like A. Bastian (*Schöpfung und Entstehung* and *Der Mensch in der Geschichte*), who still hold to the doctrine of the fixity of species, and the essential difference between human history and sequences of natural events, are now the exceptions. With anthropology we must connect that new science of comparative human psychology (*Völkerpsychologie*) which has sprung up of late years.

Origin of Language.—Of the problems which fall under this science of man's genesis and development, none has more of philosophic interest than the question of the origin of language. This question, which lies at the very threshold of a proper understanding of the relation of man's mental nature to that of the lower animals, is touched on by Mr. Darwin himself in his *Descent of Man.* In Germany it is being earnestly discussed by a number of writers, on whom the influence of Mr. Darwin's theory of human descent is very marked. Among the writers who have explicitly applied the method of evolution, as defined by Mr. Darwin, to the explanation of language, may be mentioned A. Schleicher,[1] L. Geiger,[2] Dr. G. Jäger,[3] Wilhelm Bleek,[4] and Ernest Haeckel.[5] Jäger, who assumes that man is the immediate descendant of ape-like progenitors, connects the first beginnings of human speech with a superiority in the command of the actions of respiration which is involved in man's erect posture.

(*d*) *Darwinism and Psychology.*—From anthropology we pass to psychology. Here the influence of Darwinism meets us too. Among recent psychologists W. Wundt, in his *Grundzüge der physiologischen Psychologie*, makes frequent use of the doctrine of a gradual evolution of mental dispositions by means of heredity. He would, for example, explain the rapidity with which the space-perception is formed in the infant mind by help of such an inherited disposition. Wundt appears to lean to the hypothesis of ultimate sentient elements, by the summation of whose rudimentary feelings arises the unity of consciousness.

The wider consequences of Mr. Darwin's theory in the domain of psychology are briefly indicated by Dr. Georg von Giz'ycki, in his little work *Die philosophischen Consequenzen der Lamarck-Darwin'schen Entwicklungstheorie.* He argues against attributing sensation to all material things, which supposition (unlike Professor Clifford) he does not regard as a necessary consequence of the evolution hypothesis. He distinctly seizes the bearing of this doctrine on our conception of mind (animal as well as human) as identical in its fundamental laws, and as presenting to the psychologist a single serial development; and he still further follows Mr. Spencer in connecting all mental activity with vital functions essential to the preservation of the individual and of the race. Finally, he adopts the view that the mental organism depends on the laws of the external universe. The harmony or adaptation which we see holding between thoughts and things must be interpreted as the effect of the latter acting on and modifying the former in conformity with themselves.

Darwinism and Ethics and Religion.—Passing now to the region of practical philosophy, we find that Darwinism has occasioned in Germany, as in England, a good deal of curious speculation. Among the many writers who have touched on the aspects of Darwinism we can only refer to one or two. Among these we may mention Dr. Paul Rée, who, in a recent work, *Der Ursprung der moralischen Empfindungen*, argues that moral dispositions or altruistic impulses have been developed as useful to society, yet rather oddly combines with this idea the pessimistic doctrine that man is not on the whole growing more moral. Again Dr. Giz'ycki, in the work just referred to, emphasizes the bearing of the doctrine of human descent on our feeling towards the lower animals as closely linked to ourselves. He goes on to show that this doctrine involves the most definite and stringent form of determinism, and so has a bearing on our ideas of right and wrong, blame, etc. The writer thinks Darwinism by no means excludes a teleological conception of the world as a process striving towards the highest manifestation of mental life, and this idea leading back to that of an absolute first cause of the order of the world, becomes the starting-point for religious and æsthetic aspiration. In Dr. G. Jäger's work, *Die Darwin'sche Theorie und ihre Stellung zu Moral und Religion*, we find a practical deduction from Darwinism which curiously contrasts with that of Dr. Giz-'yeki. Jäger argues that this doctrine teaches us to place ourselves in the greatest possible opposition to the lower animals. The aim of morality, as taught by Darwinism, must be to develop to the utmost those excellences which mark off man from the brute. The author seeks to account for the genesis of social institutions and religious ideas, as utilities which benefited those communities possessing them in the struggle for existence.

[2] *Der Ursprung der Sprache.*

[3] *Ueber den Ursprung der menschlichen Sprache.*

[4] *Ueber den Ursprung der Sprache.*

[5] *The History of Creation*, ii. p. 300 sq.

A work in which are traced the ethical and religious consequences of the doctrine of evolution is *The Old Faith and the New* of David Strauss. According to Strauss, all morality has its root in the recognition and realization of the idea of kind in ourselves and in others. He argues from the fact that nature has produced man as her last and highest achievement, and the lower forms of creatures but as steps in the progress towards man, that our end and aim must be the furtherance of that which marks us off from the brutes. Religion again begins with the sense of unity with nature, and the new doctrine of the cosmos enables us to regard nature as the source whence our life, as all life, springs.

Interpretation of Modern Scientific Doctrine.—A word or two in conclusion respecting what is known as the modern doctrine of evolution. It is important to emphasize the fact that this is a scientific doctrine, which has been built up by help of positive research. As such, of course, it embodies the mechanical, as distinguished from the teleological, view of nature's processes. Yet it still awaits its final philosophic interpretation. We cannot yet say under what head of our historical scheme it is destined to fall.

We think the question of the universal applicability of the doctrine to physical and mental phenomena may be allowed. There are no doubt wide gaps in our knowledge of both orders. Thus it may reasonably be doubted whether physical theory can as yet enable us fully to see the necessity of that universal process from the homogeneous to the heterogeneous in which evolution consists; yet in a rough and vague way the process is being made theoretically intelligible. Again, the transition from the inorganic to the organic is, as Professor Tyndall has lately told us, far from being conceivable in the present state of our knowledge; and this seems to be implied in the remarkable hypothesis by which Professor Helmholtz and Sir W. Thomson seek to account for the first appearance of life on our planet. Yet we may reason from the general tendencies of research that this step may some day be hypothetically explained in physical and mechanical terms. Again, in spite of Mr. Spencer's brilliant demonstration of the general continuity of mental life, much remains to be done before all the steps in the process (*e.g.*, from particular to general knowledge, from single feelings to self-consciousness) are made plain. Nevertheless, we may even now dimly see how such mental processes may be knit together in one larger process.

Allowing, then, that the doctrine of evolution as a scientific hypothesis is probably true, the question arises, What is its exact philosophical purport? How far does it help to unify our knowledge, and is it the final explanation of the complex events of our world?

First of all, then, as a unifying generalization, it is clearly limited by the fact of the correlation of mental and physical evolution. These two regions of phenomena may be seen to manifest the same law, yet they cannot be identified. All the laws of physical evolution can never help us to understand the first genesis of mind; and this difficulty is in no way reduced by Mr. Spencer's conception of a perfect gradation from purely physical to conscious life. The dawn of the first confused and shapeless feeling is as much a "mystery" as the genesis of a distinct sensation. Our best exponents of evolution, including Professor Du Bois Reymond (*Ueber die Grenzen des Naturerkennens*, p. 25 *sq.*), fully recognize this difficulty. We have here much the same "mystery" which meets us in the conversion of a nerve-stimulus into a sensation in the developed organism. The sequence is unlike any properly physical succession, and so cannot be further explained by being brought under a more general law. Not only so, the doctrine of the conservation of energy, as applied to organic processes, leads to the conclusion that the genesis of mind in general and of every single mental phenomenon is, from a physical point of view, something nonessential.

We may, no doubt, avoid this difficulty, in appearance, at least, by assuming that all material processes down to the vibrations of the indivisible atoms are accompanied with a mode of feeling. This may, of course, be proposed as a properly scientific hypothesis, and as involving no metaphysical assumptions respecting the nature of atoms. The great difficulty here would be, how we are to conceive of modes of sensibility that do not enter into a collective consciousness, and which appear to lack all the characteristics of our own conscious life.

Even, however, if this huge difficulty of the genesis of mind is got over, there still remain limits to the explanation effected by the doctrine of evolution. Thus, while it might be able to deduce all the processes of physical evolution from a few assumptions respecting primitive matter and its laws, it would have no such data for resolving all these steps in the mental process which result in a heterogeneous mode of feeling. How, for instance, is it to account on general principles, and by *a priori* reasoning, for the differentiation of a vague tactual sensibility into what we know as sight and hearing—sensibilities which underlie all our ordinary conceptions of the physical world? Here are manifestly set rigid limits to the explanation effected by the doctrine of evolution, the limits which J. S. Mill has laid down as those of all kinds of explanation of phenomena. The doctrine by no means helps us to resolve all laws of succession into one.

The other limits set to the explanatory power of the modern doctrine have already been hinted at. Thus the doctrine sets out from a given point in time, at which it assumes a definite arrangement of material (and mental) elements to have obtained. "Of the beginning of the universe," says Professor Clifford, "we know nothing at all." Again, Professor J. Clerk Maxwell tells us[1] that we must from the first assume an infinite number of molecules exactly alike in their weight and rate of vibration; and he distinctly argues against the supposition that this system of like elements can have been evolved. There is room then for the question, how this particular order of elements arose. And even if we go further back, and make with Mr. Spencer the large assumption that these various classes of molecules have been evolved from perfectly homogeneous first elements, one may still ask for an explanation of this original homogeneity. In short, it is plain that every doctrine of evolution must assume some definite initial arrangement, which is supposed to contain the possibilities of the order which we find to be evolved, and no other possibility.

Such being the limits set to the scope of explanation by the idea of evolution, the question arises whether these apparently permanent gaps in our scientific knowledge can be filled up by extra-scientific speculations. One may seek to show the need of such a metaphysical interpretation of evolution by a reference to the very nature of the doctrine. As a scientific truth, it is simply the highest generalization respecting the order of phenomena in time, and as such makes no assumptions with regard to the ultimate nature of that matter, force, and mind, of which it speaks. What, it may be asked, are the realities corresponding to these terms, and how are we to conceive of their mutual relations? Each of the supposed deficiencies in the doctrine of evolution just referred to leads us back to those various metaphysical doctrines in which, as we have seen, the idea of evolution has usually clothed itself. In order to understand what Mr. Martineau calls the whence as distinguished from the when, and to provide a substantial support for the thread of phenomenal events, it would seem as if we must fall back on some ultimate philosophic assumption respecting the efficient principle in the process.

With respect to metaphysical dualism, it must be said that it leaves us pretty much where we were. The correlation of two distinct substances and their manifestations, in the way required by the doctrine of evolution (whether this correlation be universal or not), needs explanation as much as the correlation of the two sets of phenomena. On the other hand, materialism, spiritualism, and the so-called monism, have each their merits and their drawbacks as helps to the interpretation of evolution. If materialism recommends itself by assuming the fewest possible principles, it is exposed to the objection that it bids us conceive a reality which is wholly distinct from mind. Further, it fails to give any intelligible account of the rise and progress of mental activity. Again, spiritualism assists us in accounting for the genesis of mind, and for the appearance of intelligent order in the world. Yet it is questionable whether this doctrine, assuming as it does some form of unconscious mind (whether as world-soul or as elements of feeling), is not beset with as many difficulties as it resolves. Further, it may be doubted whether the spiritualistic idea, in its common pantheistic form, has yet succeeded in rendering intelligible the fixed mechanical order which marks all stages of evolution. Finally, it may be allowed that the monistic doctrine of one reality with two faces does in appearance lift us over the difficulties which beset the materialistic and the spiritualistic interpretation of evolution. Only is it in truth anything more than a verbal simplification, and does it not rather leave us confined in that dualism where science has to land us?

---

[1] *Discourse on Molecules.* See also the very interesting section on the "Nature and Origin of Molecules," which concludes the work on the *Theory of Heat.*

It would thus seem that the doctrine of evolution has by no means as yet received its final philosophic character. No one of the metaphysical doctrines which are at our command is so plainly and completely adapted to transform it into a final doctrine of existence, that it must of necessity be accepted at once and by all.

To this we must now add that to many minds this resort to a metaphysical principle as the support of the process of evolution will not be held to be necessary. A positivist, who thinks that our knowledge of the universe must for ever be limited to phenomena, is at perfect liberty to accept the doctrine of evolution and to regard it as an ultimate expression for the order of the world. Nay more, the empirical idealist—who may perhaps be defined as a positivist that has fully analyzed his "phenomena"—can accept and give a meaning to the doctrine of evolution as formulating the order of sensations, actual and possible, of conscious minds. Mr. Spencer somewhere says that, if idealism is true, evolution is a dream. Yet this assertion may be reasonably disputed. It may perhaps seem staggering to be told that evolution postulates vast periods of time in which there existed no mind to experience the sensations into which the world is on the idealistic hypothesis resolved. Yet this difficulty is only apparent, since past physical evolution stands for a projection, so to speak, of now existing minds, and for an order of sensations conceived as possible under other and imaginable circumstances.[1] To the empirical idealist physical evolution stands for an imagined order of perceptions in an indefinite number of minds, mental evolution for actual successions of feeling in many minds, and the transition from the one to the other means the succession of actual states of consciousness on possible or imagined states. The unity of the world-process arises from the ability of the individual mind, which now reflects on these many successions, to gather them up by a series of acts of imagination into a collective ideal experience for itself.

Thus the doctrine of evolution seems to be susceptible of statement in terms of idealism as easily as in terms of realism. In truth, each mode of viewing the process is at once possible and beset with difficulties. The difficulty of giving an idealistic interpretation arises from the popular distinction of mind or perception and something beyond and independent of this. The difficulties of giving a realistic interpretation have in part been stated already in speaking of the different realistic interpretations (materialism and spiritualism). To these must be now added the fundamental obstacle to all realism, which shows itself, in a specially striking way, in relation to the doctrine of evolution,—namely, the difficulty of conceiving in terms of human consciousness something which is independent of, antecedent to, and creative of, this consciousness.

It may be asked, perhaps, whether the doctrine of evolution, by providing a new conception of the genesis of our cognitions, has anything to say to the question of a real independent object. What the doctrine effects with respect to such cognitions as those of space is to show that the bare fact of intuitiveness or innateness does not establish their non-empirical or transcendental origin. Similarly it may be held that the doctrine opens a way of accounting for the growth of the idea of independent realities, supposing this to be now an innate disposition of the mind—viz., by regarding this idea as arising in a succession of many generations, if not out of, yet by help of, certain elements or aspects of experience. It may, however, be maintained that the idea is not even suggested by experience; if so, it would follow from the evolution theory that its present persistence represents a permanent mental disposition to think in a particular way. Even then, however, the question would remain open whether the permanent disposition were an illusory or trustworthy tendency, and in deciding this point the doctrine of evolution appears to offer us no assistance.[2]

As a scientific doctrine, whatever its ultimate interpretation, evolution has a bearing on our practical, *i.e.*, moral and religious ideas. This has already been shown in part by writers from whom we have quoted. Among other results, this doctrine may be said to give new form to the determinist theory of volition, and to establish the relativity of all moral ideas as connected with particular stages of social development. It cannot, as Mr. Sidgwick has shown, provide a standard or end of conduct except to those who are already disposed to accept the law *sequi naturam* as the ultimate rule of life. To such it furnishes an end, though it would still remain to show how the end said to be unconsciously realized by nature, the well-being of individuals and of communities, is to be adjusted to the ends recognized in common-sense morality, including the happiness of all sentient beings. It may be added that the doctrine, by assigning so great an importance to the laws of inheritance as means of raising the degree of organization and life, may be expected to exert an influence on our ideas of the solidarity of the present generation and posterity, and to add a certain solemnity to all the duties of life, prudential morality included.

The bearing of the doctrine of evolution on religious ideas is not so easy to define. Mr. Spencer considers the ideas of evolution and of a pre-existing mind incapable of being united in thought (see his rejoinder to Dr. Martineau, *Contemporary Review*, vol. xx. p. 141 *sq.*). Yet, according to others, the idea is by no means incompatible with the notion of an original Creator, though it serves undoubtedly to remove the action of such a being further from our ken. At first sight it might appear that the doctrine as applied to the subjective world, by removing the broad distinction between the human and the animal mind, would discourage the hope of a future life for man's soul. Yet it may be found, after all, that it leaves the question very much where it was. It may perhaps be said that it favors the old disposition to attribute immortality to those lower forms of mind with which the human mind is found to be continuous. Yet there is nothing inconsistent in the supposition that a certain stage of mental development qualifies a mind for immortality, even though this stage has been reached by a very gradual process of development. And if, as might be shown, the modern doctrine of evolution is susceptible of being translated into terms of Leibnitz's hypothesis of indestructible monads, which include all grades of souls, then it is clearly not contradictory of the idea of immortality.

Very interesting is the bearing of the doctrine of evolution on that æsthetico-religious sentiment towards the world which has taken the place of older religious emotions in so many minds. First of all by destroying the old anthropo-centric view of nature, according to which she is distinct from and subordinated to man, this doctrine favors that pantheistic sentiment which reposes on a sense of ultimate identity between ourselves and the external world. In a sense it may be said that the new doctrine helps to restore the ancient sentiment towards nature as our parent, the source of our life. It is well to add, however, that the theory of evolution, by regarding man as the last and highest product of nature, easily lends support to the idea that all things exist and have existed for the sake of our race. This seems, indeed, to be an essential element in any conception we can form of a rationally evolved universe.

A reference must be made, in closing this article, to the optimistic aspect of the doctrine of evolution. That there is a tone of optimism in much of the more popular exposition of the doctrine of evolution needs not be proved. There is no doubt, too, that both in Mr. Darwin's and Mr. Spencer's theories there are ideas which tend to support a cheerful and contented view of things. The idea of the survival of the fittest, and of evolution as a gradual process of adaptation to environment, lend themselves to this kind of thought. Indeed, Du Bois Reymond, in the lecture on Leibnitz already referred to, seriously argues that the doctrine of evolution provides a scientific equivalent to that philosopher's remarkable conception of the best of all possible worlds. On the other hand, as the present writer has elsewhere shown, Mr. Darwin's doctrine of evolution contains elements which are fitted to tone down our estimate of the value of the world viewed as the seat of conscious sentient life. The pain involved in the renewed struggle for existence is a large drawback from the gains of human progress and of organic development as a whole. More than this, the principle of natural selection appears almost to favor a pessimist view of the world, in so far as it implies the tendency of organic forms to multiply down to the limits of bare existence.

---

[1] It may be added that the hypothesis of the uniform correlation of the physical and the mental enables us to assign an element of actuality (mental life) to the remote periods here spoken of.

[2] For a discussion of the relations of this doctrine to realism, see the essay already referred to in Mr. Sully's volume *Sensation and Intuition.*

EVORA, a city of Portugal, capital of the province of Alemtejo, is situated on an eminence in the centre of a fertile plain, 85 miles E. by S. of Lisbon. It is surrounded by ramparts flanked with towers, and has two forts, but all in a ruinous condition, and quite useless as means of defence. The streets are narrow, crooked, and filthy, and the houses old and ill built. The cathedral is a magnificent Gothic edifice with an altar in the Italian style, extremely rich, and decorated with variously colored marbles. Evora is the see of an archbishop, and besides the cathedral has several churches, convents, and hospitals, a house of charity, barracks, a diocesan school, and a museum. A university, founded in 1550, was abolished on the expulsion of the Jesuits in the 18th century. An ancient aqueduct and an ancient tower, till a few years ago in pretty good preservation, have been partly demolished to make room for a market. They were long believed to have been of Roman origin, but are now known to have been constructed about 1540 in the reign of Don John III., at the instance of an antiquarian named Resende. The aqueduct was constructed on the site of the old Roman one. The remains of what is said to have been a temple of Diana still exist, but the place is now used as a slaughter-house. Evora, under the name of Ebora, was an important military station in the time of the Romans, and was called *Liberalitas Juliæ* on account of certain municipal privileges bestowed on it by Cæsar. In 712 it was conquered by the Moors and named Jabura, but they were deprived of it in 1162 by an order of Christian knights.

EVREUX (the ancient *Mediolanum*, and afterwards *Eburovices*), a town of France, capital of the department of Eure, is situated on the Iton, an affluent of the Eure, 67 miles W.N.W. of Paris by railway. The town is generally well built, and still contains many antique timber-framed houses. It is the seat of a bishop, and its cathedral is one of the most ancient and curious in France. It dates from the 11th century, and is a very imposing cruciform structure, though not uniform in style. The north transept and the portal are in the flamboyant Gothic, elaborately ornamented; the west front is in the Italian style. The beautiful rose window in the south transept, and the wooden screens of the side chapels round the choir, showing the flamboyant Gothic style modified by the reviving Italian, also merit notice. The lady chapel is of elegant architecture, with painted glass equally remarkable for its fine execution and perfect preservation. At the intersection of the nave and transepts rises an octagonal tower supported on four pillars, and surmounted by a pyramidal spire of open stonework. The church of St. Taurin also displays various styles of architecture, and contains the shrine of St. Taurin, a work of the 13th century. The episcopal palace, which dates from the 15th century, is a beautiful structure. Among the other objects of interest are the clock-tower built in the 15th century, the abbey of St. Saviour, the ancient Séminaire des Eudistes now used as a prison and assize buildings, the museum of antiquities, the town-hall, the prefect's residence, the theatre, the public library, the botanic garden, and the promenades. Evreux is famed for its manufacture of tools, and for stocking making; brewing, distilling, dyeing, tanning, and paper making are its other principal industries. At Vieil Evreux the remains of a Roman theatre, a palace, baths, and an aqueduct have been discovered, and various relics which are now deposited in the Musée d'Antiquités.

Evreux existed at a very early period. About the end of the 10th century Richard I. of Normandy gave it to his son Robert; and early in the 12th century it came by inheritance into the house of Montfort, from whom it was bought by Philip Augustus of France. Philip II. gave it to his brother Prince Louis, who in 1316 was created Count of Evreux. Count Philip of Evreux acquired by marriage the kingdom of Navarre, and Charles III. of Navarre sold it to Charles VI. of France. Charles VII. gave it in 1426 to John Stuart, earl of Darnley, after whose death it again came into the possession of the crown. Charles IX. bestowed it, along with the title, on his brother the duke of Alençon, but on his death in 1584, it finally returned into the possession of the crown.

EWALD, Heinrich Georg August von (1803–1875), Orientalist, biblicist, and theologian, was born, November 16, 1803, at Göttingen, where his father followed the occupation of a linen-weaver. After receiving the usual preliminary training, he entered the university of his native town in 1820; and there, with Eichhorn as teacher, he at once began to devote himself specially to the study of Hebrew and its cognates. At the close of his academical career in 1823 he was appointed to a mastership in the gymnasium at Wolfenbüttel; but soon afterwards (in the spring of 1824) he was, at the instance of Eichhorn, recalled to Göttingen as repetent, or theological tutor, and in 1827 (the year of Eichhorn's death) he became professor *extraordinarius* in philosophy, and lecturer in Old Testament exegesis. In 1831 he was promoted to the position of professor *ordinarius* in philosophy; and in 1835 he entered the faculty of theology, taking the chair of Oriental languages. Two years later occurred the first important episode in his studious life, which until then had been uninterrupted in its even tenor except by journeys in 1826, 1829, and 1836 to Berlin, Paris, and Italy, for the purpose of consulting rare and important Oriental manuscripts. In 1837, on the 18th November, along with six of his colleagues (Dahlmann the historian, Weber the electrician, Gervinus the critic, the brothers Grimm, and W. E. Albrecht) he signed a formal protest against the arbitrary proceeding of King Ernst August (duke of Cumberland) in abolishing the liberal constitution of 1833, which had been granted to the Hanoverians by his predecessor William IV. This bold action of the seven professors made them very popular and famous in the country; but it led to their speedy expulsion from the university (14th December). Early in 1838 Ewald received a call to Tübingen, and there for upwards of ten years he held a chair as professor *ordinarius*, first in philosophy and afterwards, from 1841, in theology. To this period belong some of his most important works, and also the commencement of his bitter feud with F. C. Baur and the Tübingen critical school. In 1848, "the great shipwreck-year in Germany," as he has called it, he was invited back to Göttingen on honorable terms,—the liberal constitution having been restored. He gladly accepted the invitation, for though well treated in Würtemberg (he had been ennobled by the king in 1841), he had never learned to regard his sojourn there as anything else than a period of exile. In 1862–63 he took an active part in a movement for reform within the Hanoverian church, and he was a member of the synod which passed the new constitution. He had an important share also in the formation of the Protestantenverein, or Protestant association, in September, 1863. But the chief crisis in his life arose out of the great political events of 1866. His loyalty to King George (son of Ernst August) would not permit him to take the oath of allegiance to the victorious king of Prussia, and in consequence of his refusal to do so he was ultimately placed on the retired list, though with the full amount of his salary as pension. Perhaps even this degree of severity might have been held by the Prussian authorities to be unnecessary, had Ewald been less exasperating in his language. The violent tone of some of his printed manifestoes about this time, especially of his *Lob des Königs u. des Volkes*, led to his being deprived of the *venia legendi* (1868), and also to a criminal process, which, however, resulted in his acquittal (May, 1869). Then, and on two subsequent occasions, he was returned by the city of Hanover as a member of the North German and German parliaments. In June, 1874, he was found guilty of a libel on Prince Bismarck, whom he had compared to Frederick II. and Napoleon III. —to the former in "his unrighteous war with Austria and his ruination of religion and morality," to the latter in his way of "picking out the best time possible for robbery and plunder." For this offence he was sentenced to undergo three weeks' imprisonment. He died in his 72d year, of heart-disease, May 4, 1875.

From the above brief sketch it will be seen that, even apart from his contributions to philological and biblical science, Ewald was no common man. In the whole course of his public life he displayed in a very high degree many noble characteristics,—perfect simplicity and sincerity, intensest moral earnestness, sturdiest independence, absolute fearlessness. It would be difficult to say whether the intellectual or the emotional side of his nature was most highly developed. He loved with peculiar intensity, loved freedom and truth in every domain, in politics as well as in science and in religion; and just because he loved them with all his great might, he could not help hating all that he believed to be opposed to them. It was impossible for him to be a mere critic; no reader can understand Ewald's position who allows himself to forget that his whole being was possessed with a passionately devoted faith. It was natural that such a man should be frequently engaged in controversy, and equally natural that in these circumstances the "defects of his qualities" should often become painfully apparent. It cannot be denied that in his manner of speaking about his opponents he often overstepped the limits of charity and even of justice. The peculiar character of his intellect, which was rather intuitive than inductive, made him neither a very fair nor a very effective controversialist. No one equalled him in the power of comprehending in a single survey a vast circle of complicated facts, and almost instinctively divining their scientific unity; but the results attained in this way presented themselves to his mind with such intuitive conviction that he was impatient of all objection, and little able to do justice to scholars of a different mental habit. Yet in controversy he probably received injustice more often than he inflicted it; even his extremest views have generally been found to contain much that is true and valuable; and the great Arabist Fleischer is almost the only scholar who gained a conspicuous victory over him on an unambiguous philological issue. As a teacher he had a remarkable power of kindling enthusiasm; and he sent out many distinguished pupils, among whom may be mentioned Hitzig, Schrader, Nöldeke, Diestel, and Dillmann. His disciples have not been all of one school, any more than were those of Socrates; but many eminent moderns who are apparently farthest removed from his influence are only developing some of the fruitful ideas which in the exuberance of his wealth he was wont to fling out by handfuls.

Of no writings more truly than of his could it be said that they are the reservoirs into which, without any waste, the entire energy of a life has been stored. For more than half a century his pen was never idle; from 1823 onwards hardly a year passed which was not marked by the appearance of some highly important contribution to the sciences he loved. By the publication of his *Hebrew Grammar* he inaugurated a new era in biblical philology. All subsequent works in that department have been avowedly based on his. It has already been superseded in parts, especially in its accidence; but the syntax still remains unexcelled for the sagacity with which dry rules are made intelligible and interesting by continued reference to the fundamental laws of language and thought. But even when his *Lehrbuch* shall have become entirely antiquated, to him will always belong the honor of having been, as Hitzig has called him, "the second founder of the science of Hebrew language." As an exegete and biblical critic no less than as a grammarian he has left his abiding mark. It is hardly an exaggeration to say that the publication of his *Geschichte des Volkes Israel* was epoch-making in that branch of research, as much as was the work of Niebuhr in relation to the history of Rome. In its final form, the result of thirty years' labor, it is a noble monument to the genius of its author. No one can fail to be struck with the profundity of insight and patience of research which it displays. While in every line it bears the marks of Ewald's intense individuality, it is at the same time a highly characteristic product of the age, and even decade, in which it first appeared. If it is obviously the outcome of immense learning on the part of its author, it is no less manifestly the result of the speculations and researches of many laborious predecessors in all departments of history, theology, and philosophy. Especially is it indebted to the so-called "destructive" criticism. The Reformation had destroyed that mediæval conception of the Bible which took no account of literary history or doctrinal development at all; and subsequent researches, especially since those of Astruc, had made it abundantly clear that the conditions under which the Old Testament books had come into being were much more complicated than had been at one time supposed. Criticism, however, could not possibly rest satisfied with these purely negative results. If for a time it seemed as if the sacred literature had been reduced to a mere chaos of fragments, which men might well despair of ever being able to reduce to harmony and order, the historical sense had been developing no less remarkably than the spirit of criticism. Taught by some of the more modern schools of philosophy, men had been learning to take larger, and therefore juster, views of the principles that underlie all national histories and the general history of the human race. It was impossible that such a phenomenon as the Jewish people and their literature should be permanently set aside as wholly incomprehensible. The world was only waiting for a bold and vigorous constructive genius like that of Ewald to bring together the scattered fragments, and construe them into an intelligible unity; to show, for example, that, if the Psalter could no longer be regarded as the record of the spiritual experience of the individual to whom it had been traditionally ascribed, it became all the more precious when known to embody all the highest aspirations and purest joys and noblest sorrows of many centuries of national life; and that if the legislation of the Pentateuch was not indeed, as had once been supposed, the work of a few quiet months, it gained in interest and instructiveness when known to be the slow growth of many busy generations. Taking up the idea of a divine education of the human race, which Lessing and Herder had made so familiar to the modern mind, and firmly believing that to each of the leading nations of antiquity a special task had been providentially assigned, Ewald felt no difficulty about Israel's place in universal history, or about the problem which that primitive and highly-endowed race had been called upon to solve. The history of Israel, according to him, is simply the history of the manner in which the one true religion really and truly came into the possession of mankind. Other nations, indeed, had attempted the highest problems in religion; but Israel alone had, in the providence of God, succeeded, for Israel alone had been inspired. Such is the supreme meaning of that national history which began with the exodus and culminated (at the same time virtually terminating) in the appearing of Christ, the supremely perfect revelation or self-manifestation of God. The historical interval that separated these two events is treated as naturally dividing itself into three great periods,—those of Moses and the theocracy, of David and the monarchy, of Ezra and the hagiocracy. The periods are externally indicated by the successive names by which the chosen people were called—Hebrews, Israelites, Jews. The events prior to the exodus are relegated by Ewald to a preliminary chapter of primitive history; and the events of the apostolic and post-apostolic age are treated as a kind of appendix. The entire construction of the history is based, as has already been said, on a critical examination and chronological arrangement of the available documents. So far as the results of criticism are still uncertain with regard to the age and authorship of any of these, Ewald's conclusions must of course be regarded as unsatisfactory; and it cannot be denied that later investigations have shown that in many important points his firm faith that finality had been attained was illusory. These admissions, however, hardly affect the permanent value of his work. It will continue to be a storehouse of learning for all subsequent investigators in the field of sacred history, and it will be increasingly recognized as a work of rare genius. It would be impossible to praise too highly the conscientiousness with which the minutest features of the history have been carefully scanned; the marvellous power of combination which, at even the most unlikely points, can draw the most graphic illustrations from contemporary prophets and poets; the vividness with which, not only the politics, but also the religion, the arts, the literature, the domestic life, of each successive period are depicted; the loving enthusiasm of the student who believes that those only are the enemies of the Bible who fail to investigate it, or who fail to investigate it thoroughly.

In his work on biblical theology, he can hardly be said to have been so successful as in some of his earlier efforts. Though a suggestive and therefore a useful book, its conclusions are vitiated in many cases by a glaring departure from the inductive method, the interpretations being often speculative rather than biblical, and unduly dominated by preconceived metaphysico-religious system of the universe.

Subjoined is a list of the more important of his works:—*Die Composition der Genesis Kritisch untersucht* (1823) [an acute and able attempt to account for the use of the two names of God without recourse to the document-hypothesis; he was not himself, however, permanently convinced by it]; *De metris carminum Arabicorum* (1825); *Das Hohelied Salomo's übersetzt u. erklärt* (1826; 3d. ed. 1866); *Kritische Grammatik der hebr. Sprache* (1827) [this afterwards became the *Ausführliches Lehrbuch der hebr. Sprache* (8th ed. 1870); and it was followed by the *Hebr. Sprachlehre für Anfänger* (4th ed. 1874)]; *Ueber einige ältere Sanskritmetra* (1827); *Liber Vakedii de Mesopotamiæ expugnatæ historia* (1827); *Commentarius in Apocalypsin Johannis* (1828); *Abhandlungen zur biblischen u. orientalischen Literatur* (1832); *Grammatica critica linguæ Arabicæ* (1831–33); *Die poetischen Bücher des alten Bundes* (1835–37, 3d. ed. 1866–67); *Die Propheten des alten Bundes* (1840–41, 2d. ed. 1867–68); *Geschichte des Volkes Israel* (1843–59, 3d ed. 1864–68); *Alterthümer Israels* (1848); *Die drei ersten Evangelien übersetzt u. erklärt* (1850); *Ueber das äthiopische Buch Henoch* (1854); *Die Sendschreiben des Apostels Paulus übersetzt u. erklärt* (1857); *Die Johanneischen Schriften übersetzt u. erklärt* (1861–62); *Ueber das vierte Esrabuch* (1863); *Sieben Sendschreiben des neuen Bundes* (1870); *Das Sendschreiben an die Hebräer u. Jakobos' Rundschreiben* (1870); *Die Lehre der Bibel von Gott, oder Theologie des alten u. neuen Bundes* (1871–75). The *Jahrbücher der biblischen Wissenschaft* (1849-65) were edited, and for the most part written, by him. He was the chief promoter of the *Zeitschrift für die Kunde des Morgenlandes*, begun in 1837; and he frequently contributed on various subjects to the *Götting. gehlerte Anzeigen*. He was also the author of many pamphlets of an occasional character.

The following have been translated into English:—*Hebrew Grammar*, by Nicholson (from 2d German edition), Lond. 1836; *Introductory Hebrew Grammar* (from 3d German edition), Lond. 1870; *History of Israel*, 5 vols. (corresponding to vols. i.–iv. of the German), by Russell Martineau and J. Estlin Carpenter, Lond. 1867–74; *Antiquities of Israel*, by H. S. Solly, Lond. 1876; *Commentary on the Prophets of the Old Testament*, by J. Frederick Smith, 2 vols., Lond. 1876–77; *Isaiah the Prophet*, chaps. i.–xxxiii., by O. Glover, Lond. 1869; *Life of Jesus Christ*, also by O. Glover, Lond. 1865. (J. S. BL.)

EWALD, JOHANNES (1743–1781), the greatest lyrical poet of Denmark, was the son of a melancholy and sickly chaplain at Copenhagen, where he was born on the 18th of November, 1743. At the age of eleven he was sent to school at Schleswig, his father's birth-place, and returned to the capital only to enter the university in 1758. His father was by that time dead, and in his mother, a frivolous and foolish woman, he found neither sympathy nor moral support. At fifteen, he fell passionately in love with "the delicate, noble, majestic Arense," a girl whose father, later on, married the poet's mother; and the romantic boy resolved on various modes of making himself admired by the young lady. He began to learn Abyssinian, for the purpose of going out as a missionary to Africa, but this scheme was soon given up, and he persuaded a brother, four years older than himself, to run away that they might enlist as hussars in the Prussian army. They managed to reach Hamburg just when the Seven Years' War was commencing, and were allowed to enter a regiment. But the elder brother soon got tired and ran away, while the poet, after a series of extraordinary adventures, deserted to the Austrian army, where from being drummer he rose to being sergeant, and was only not made an officer because he was a Protestant. In 1760 he was weary of a soldier's life, and deserted again, getting safe back to Denmark. For the next two years he worked with great diligence at the university, but the Arense for whom he had gone through so much hardship and taken so much pains married another man almost immediately after Ewald's final and very successful examination. The disappointment was one from which he never recovered. He plunged into dissipation of every kind, and gave his serious thoughts only to poetry. In 1763 his first work, a perfunctory dissertation *De Pyrologia Sacra*, first saw the light. In 1764 he made a considerable success with a short prose story, *Lykkens Tempel* (The Temple of Fortune), which was translated into German and Icelandic. On the death of Frederick V., however, Ewald first appeared prominently as a poet; he published in 1766 three *Elegies* over the dead king, which were received with universal acclamation, and of which one, at least, is a veritable masterpiece. But his dramatic poem *Adam og Eva* (Adam and Eve), by far the finest imaginative work produced in Denmark up to that time, was rejected by the Society of Arts in 1767, and was not published until 1769. At the latter date, however, its merits were perceived. In 1770 Ewald attained success with *Philet*, a narrative and lyrical poem, and still more with his splendid *Rolf Krage*, the first original Danish tragedy. For the next ten years Ewald was occupied in producing one brilliant poetical work after another, in rapid succession. In 1771 he published *De brutale Klappers* (The Brutal Clappers), a tragi-comedy or parody satirizing the dispute then raging between the critics and the manager of the Royal Theatre; in 1772 he translated from the German the lyrical drama of *Philemon and Baucis*, and brought out his comedy of *Harlequin Patriot*, a satire on the passion for political scribbling created by Struensee's introduction of the liberty of the press. In 1773 he published *Pebersvendene* (Old Bachelors), a comedy. In 1771 he had already collected some of his lyrical poems under the title of *Adskilligt af Johannes Ewald* (Miscellanies). In 1774 appeared the heroic opera of *Balder's Död* (Balder's Death), and in 1779 the finest of his works, the lyrical drama *Fiskerne* (The Fishers), which contains the Danish National Song, "King Christian stood by the high Mast," his most famous lyric. In the two poems last mentioned, however, Ewald passed beyond contemporary taste, and these great works, the pride of Danish literature, were coldly received. But while the new poetry was slowly winning its way into popular esteem, the poet did not lack admirers, and at the head of these he founded in 1775 the Danish Literary Society, a body which became influential, and which made the study of Ewald a cultus. But the poet's health had broken; when he was writing *Rolf Krage* he was already an inmate of the Consumptive Hospital, and when he seemed to be recovering, his health was shattered again by a night spent in the frosty streets. He embittered his existence by the recklessness of his private life, and finally, through a fall from a horse, he ended by becoming a complete invalid. His last ten years were full of acute suffering; his mother treated him with cruelty, his family with neglect, and but few even of his friends showed any manliness or generosity towards him. In 1774 he was placed in the house of an inspector of fisheries at Rungsted, where Anna Hedevig Jacobsen, the daughter of the house, tended the wasted poet with infinite tenderness and skill. He stayed in this house for three years, and wrote there some of his finest later lyrics. Meanwhile he had fallen deeply in love with the charming solace of his sufferings, and won her consent to a marriage. This step, however, was prevented by his family, who roughly removed him to their own keeping near Kronborg. Here he was treated so infamously that he insisted on being taken back to Copenhagen in 1777, where he found an older, but no less tender nurse, in Madame Schouw. Here he wrote *Fiskerne*, with his imagination full of the familiar shore at Hornbæk, near Rungsted. In 1780 he was a little better, and managed to be present at the theatre at the first performance of his poem. But this excitement destroyed him, and after months of extreme agony, he died on the 17th of March, 1781, and was carried to the grave by a large assembly of his admirers, since he was now just recognized by the public for the first time as the greatest national poet. Among his papers were found fragments of three dramas, two on old Scandinavian subjects, entitled *Frode* and *Helgo*, and the third a tragedy on the story of *Hamlet*, which he meant to treat in a way wholly distinct from Shakespeare's.

Ewald belongs to the race of poetical reformers who appeared in all countries of Europe at the end of last century; but it is interesting to observe that in point of time he preceded all of them. He was born six years earlier than Goethe and Alfieri, sixteen years before Schiller, nine years before André Chénier, and twenty-seven years earlier than Wordsworth, but he did for Denmark what each of these poets did for his own country. Ewald found Danish literature given over to tasteless rhetoric, and without art or vigor. He introduced vivacity of style, freshness and brevity of form, and an imaginative study of nature which was then unprecedented. But perhaps his greatest claim to notice is the fact that he was the first person to call the attention of the Scandinavian peoples to the treasuries of their ancient history and mythology, and to suggest the use of these in imaginative writing. With a coloring more distinctly modern than that of Collins and Gray, his lyrics yet resemble the odes of these his English contemporaries more closely than those of any Continental poet; from another point of view his ballads remind us of those of Schiller, which they preceded. His dramas, which had an immense influence on the Danish stage, are now chiefly of antiquarian interest, with the exception of "The Fishers," a work that must always live as a great national poem. In personal character and in fate Ewald seems to have been not unlike Heinrich Heine.

The first collected edition of Ewald's works began to appear in his life-time. It is in four volumes, 1780–1784. They have constantly been reprinted, but the standard edition is that by Liebenberg, in 8 vols., 1850–1855. (E. W. G.)

EWING, ALEXANDER (1814–1873), a clergyman of the Scotch Episcopal Church, bishop of Argyll and the Isles, was descended from an old Highland family, and was born in Aberdeen 25th March, 1814. After spending two sessions at the university of that city, where he manifested a special bent towards the study of natural history, he studied for a time at a private school in Chelsea, and in 1831 he attended the classes of chemistry, natural philosophy, and natural history in the university of Edinburgh. His uncertain health, however, compelled him for a time to suspend all systematic study. The property inherited from his father rendered it unnecessary for him to adopt a profession from pecuniary considerations, and his delicate health counselled at least delay in taking such a step. Accordingly, for some time after his marriage he occupied himself chiefly in the cultivation of his literary and artistic tastes, residing at first in the north of Scotland, and in October, 1838, journeying to Italy, where he remained till April, 1841. As early as 1836, however, he had begun to look to the church as a profession; and in October, 1838, he was admitted to deacon's orders with the object of pledging himself to his future profession before leaving Scotland,—the Episcopalian Church being preferred by him to the Presbyterian, chiefly on account of its comprehensive statements regarding the subject of human redemption. Soon after his return from Italy he was requested to take the charge of the Episcopal congregation at Forres, and on accepting it he was ordained a presbyter in the autumn of 1841. He remained at Forres till 1846, when he was elected first bishop of the newly restored diocese of Argyll and the Isles, the duties of which position he discharged till his death, 22d May, 1873. In 1851 he received the degree of D.C.L. from the university of Oxford.

Though the work accomplished by Ewing was necessarily modified and circumscribed by the fact that throughout his whole life he was fettered by a delicate bodily constitution, he yet battled with the vices and religious perplexities and difficulties of his time in a spirit of buoyant cheerfulness. Perhaps his strength lay chiefly in the charm of his personal manner, in his fine tact, and his catholic sympathies; and these gradually secured him, not only the admiration and love of the people and clergy of his diocese, but a prominent position among the ecclesiastics of his own time, both in Scotland and England. In all theological discussions he contended for the exercise of a wide tolerance and charity, shrinking from condemning with ecclesiastical censure even opinions which he feared might be fraught with evil and danger to the church. He did not, indeed, attach much importance to mere ecclesiastical authority and organization, and was more solicitous about the inward than the outward unity of Christianity. His own theological position resembled very closely that of Thomas Erskine of Linlathen, and Frederick Denison Maurice; but his relation to these theologians was rather that of a friendly sympathizer than a disciple, for his opinions were the fruit of his own meditation, and were colored by his own idiosyncrasy, and their perspective was determined by his individual stand-point. Unlike theirs, his teaching was never presented in the form of a complete and elaborate theological treatise, and its purport is only to be gathered from fragmentary publications,—letters to the newspapers, pamphlets, special sermons, essays contributed to the series of *Present Day Papers*, of which he was the editor, and a volume of sermons entitled *Revelation considered as Light*, which he only lived to see through the press. The title of this volume may be taken as indicating the characteristic feature of his theology. He dwelt specially upon the illuminating power of Christianity as revealing the fatherhood of God, and thus "rolling back the clouds of human sin and sorrow," so as even ultimately to "exhaust hell of its darkness." To him each attribute of God was equally light, and therefore he did not believe that any compromise had ever been effected between them. Christ was the supreme manifestation of that light, and the Bible was but the medium of its revelation, the means for enabling it to stream in upon the soul from sources beyond the mere letter of the truths which the written word contained. One of the chief of these external sources of light, specially welcomed by Ewing, was science, to the discoveries of which he looked forward as destined to lead to the manifestation of other and higher aspects of Christianity than were yet fully realized.

Besides his strictly theological writings, Ewing is the author of the *Cathedral or Abbey Church of Iona*, 1865, the first part of which contains drawings and descriptive letter-press of the ruins by Messrs. Bucklers, architects, Oxford, and the second a history of the early Celtic church and of the mission of St. Columba. See *Memoir of Alexander Ewing, D.C.L.*, by A. J. Ross, B.D., 1877.

EXAMINATIONS. Examinations have lately come very widely into use, and call for consideration at once as educational appliances and as tests of proficiency. Something answering to examinations must enter into all effectual instruction; for in order that the pupil may gain solid advantage it is not enough that what he ought to know should be put before him—as by giving him a book, or by making him listen to lectures—but we must also see that he gets hold of it and understands it aright; this is the function of examinations as appliances for education. They have, however, another use, that of tests or instruments for selection, and this purpose may clash with the educational purpose. But though the examiners may have one purpose primarily in view, and may lay down their scheme with especial reference to it, we must bear in mind that the examination must act in both ways at once. Some sort of advantage must attend on success, or else candidates will not work for it; and, on the other hand, though an examination may only be intended to sift out the ablest, and pains may be taken to avoid giving any advantage to a particular sort of instruction, still it will be found that some particular course is most productive of marks, and this will come into favor.

The few notices which we find of examinations in old times relate to tests of qualification for professions or crafts. We gather from notices of contests between the universities and the medical corporations in London that students had to pass an examination, after going through their apprenticeship, before being allowed to practise. But we never find that an examination was the sole test; it was always attached to a prescribed course of study and service. The foundation deeds of old endowed schools sometimes contain a provision for an examination; the object of this seems to have been rather to ascertain that the teaching was satisfactory than to classify the boys, though sometimes prizes and emoluments were awarded by the examiners.

University examinations are found to take their origin from the "disputations" which appear very early in the history of universities. Dialectical discussion had entered largely into the higher education in classical times, and when the university of Bologna was incorporated as a school of law by the emperor Frederick I. in 1158, disputations soon came into use as exercises for degrees. The university of Paris, which was founded soon after, and which was a school of theology and of arts, adopted the same course; and the forms of these exercises for degrees have survived to the present time in Germany, and did not disappear in England until 1860.

A student who aimed at a degree, which formerly only the more distinguished did, acted three times as opponent to other candidates, and was in time admitted to keep his "Act." This performance began by his reading a Latin thesis, in which he maintained some position in disputation against a doctor in the faculty, as well as the above-named opponents, and, in fact, against all comers. The debate was carried on in syllogistic form; the presiding doctor eventually summed up the controversy, and usually passed a compliment on the disputant, which was the earliest form of university honors.

Academical degrees, in their origin, implied a title to teach, as is seen in the names of Doctor and Master. The notion of a university degree as a criterion of general cultivation is comparatively recent: the B.A. or first degree, which is now so important, was not known in the earliest times, and is not even now granted in the German universities. The disputations took wonderful hold of the popular mind in the Middle Ages. It may be supposed that students looked more to points that gave an opening for attack, or that might be ingeniously defended, than to the truth of the matter; and as the question would be settled by an appeal to the Bible or Aristotle, a habit of looking to authority was engendered. We may catch sight of analogous evils in the examination system; for under this the points that are most likely to yield questions are the most studied. The two plans are only different ways in which the student may make a display of the powers or the knowledge he has acquired. We may observe that disputations bring out "powers," such as ease of expression in Latin, quickness in logical fence, and fertility of resource, more thoroughly than they do actual knowledge; they are better adapted for "Arts" than for sciences.

Each member of the "faculty" had a right of putting questions to the candidate for admission into it in addition to that of formally opposing him in his "Act," and this was freely exercised. This was the germ of the examination, which has since developed itself in England, and displaced the disputation. The transition from disputations to examinations took place in England during the 18th century, and it can be clearly traced at Cambridge, where the competitive system first attracted notice, from the *éclat* attaching to the "tripos list" and the senior wranglership. The name "tripos" has given rise to various strange guesses; the facts are as follows. For the appointment of some university officers, and for settling precedency, a list of those who took their B.A. degree was drawn out in order of priority of admission. This rule of priority was originally determined by favor; it was a piece of patronage belonging to the "moderators," who presided at the acts, and the proctors; afterwards it was settled according to the performances of the candidates at the acts, and eventually by the results of an examination in mathematics and natural philosophy. The day when these bachelors were inaugurated was called the "tripos" day, because on that occasion one of the old bachelors was appointed to take his place on a stool, and to dispute with the new bachelors. It was his business to make sport by a kind of mock disputation, and he was allowed much license in his remarks. He was called "the bachelor of the stool" or "tripos," and the day was called "the tripos day." The list of names was called the tripos list, and it is probably owing to this need that there was for an order of seniority that the Cambridge tripos list came to be arranged in order of merit.

The subjects of discussion were originally taken chiefly from Aristotle; but soon after the publication of Newton's *Principia* it became usual to take one at least of the three questions which the candidate had to maintain from that work; a second was frequently taken from Newton's *Optics*, and a third from ethical philosophy. The authorities, we find, endeavored in vain to prevent ethics from being thrust aside, and to maintain something like respectability in the Latin. Interest was concentrated on the mathematical subjects, three-fourths of them belonging to what we should call mathematical physics. These subjects could not be dealt with thoroughly in a disputation, and therefore the moderators adopted the plan of giving out questions which were answered in English. This eventually led to printed papers of questions being given, and in 1838 all vestige of the "Act" for the B.A. degree disappeared, although it was retained for a time in divinity, law, and medicine.

The history of the tripos serves to bring into relief different views as to the end which an examination is meant to serve. Originally it was intended to guide men so that they might learn what was thought best for them, and in the best way; this was the educational view. But colleges had fellowships to dispose of, and the tripos list furnished a ready gauge of merit for the purpose. This made it incumbent on the moderators to exercise rigorous impartiality; and great pains were taken to secure fairness and to judge rightly. A list in order of merit would hardly have approved itself to public opinion in the way the tripos list did, but for the fact that the examination was almost entirely on one subject, and that a subject which admits of questions being set of every shade of difficulty, and for which there is a definite right and wrong. If several subjects had been combined, or if, as was the case at Oxford, the ethical element had been allowed to preponderate, the results could not have been so accurately weighed, there would have been room for difference of opinion, and the only safe course would have been to distribute the names alphabetically in several classes, or in a few classes containing wide brackets, which is nearly the same thing.

The most important change in an educational direction was effected by the influence of Dr. Whewell in 1848. He introduced a compulsory examination of adequate length in the elementary subjects, especially elementary natural philosophy; this checked the practice of reading "scraps" of the higher subjects. The old educational party aimed at turning out men in the most effective condition for the ordinary struggles of life, while a later party sought to turn out mathematicians to supply the demands of the scientific world. In the old times the notion was that the senior wrangler would go to the bar, or stay at Cambridge and follow an academical career; now his destination is very commonly a professorship in Scotland or Ireland, or in the colonies. Hence the course at Cambridge has been made to include a technically scientific as well as an educational training; and it has been thereby so much extended that the amount to be carried into the tripos is excessive. As the whole cannot be read in the three years allotted, the tripos no longer affords a fair field for all those who collect together as freshmen, as it did forty years ago. A very high place can hardly be hoped for now unless much ground has been got over before admission to the university. This point has attracted notice, and changes are about to be made (1878).

Before considering other methods, it will be well to take a general view of the action of examinations. First, it may be observed that the employment of examinations rapidly spreads. An examination at a school may at first be confined to a few subjects; it is then found that the rest are neglected, and however ill suited they are for examination, they must be brought in somehow. Again, if certain boys or classes are being prepared for an examination, the others think that they may take their ease, because they are not going to be examined, and the thoughts and interests of the teachers will commonly turn to those who have to prepare for this ordeal. Moreover, if some professions are guarded by an examination, those which are not so will become the resort of the dunces. Hence when examinations are once started they spread in all directions.

It is found that some branches of study are better suited for examination than others; and something more must be said as to the fitness of different classes of subjects for this purpose. Certain studies endow the pupil with the faculty of *doing* something he could not do before, such as that of translating foreign languages, or of solving mathematical problems; and there are others, like history, which though they may add greatly to the wealth of the man's mind, yield no such definite faculty or technical dexterity. We can test the possession of the first sort of acquirement directly, by calling on the student to put in practice the powers he is expected to have acquired. But with respect to the latter we can only ascertain that he recollects some portions of what he has prepared. By choosing these portions judiciously, we can tell whether the student has carefully studied the subject, and linked the various parts of it together, but we cannot make sure of the permanency of this knowledge. Young men used to examination will pick up just the information suited for their examination in a very short time, from an analysis or tutor's note book, and forget much in a few days. This power of "getting up" and "carrying" is not without practical value. It is the power which enables a lawyer to master a mass of details, and we may allow credit for this, for it shows a good analytical memory; but it must be observed that what is thus rewarded is not so much a knowledge of the special branch of study as a power of acquiring, which very probably might be applied to one subject as well as another.

It requires great experience and judgment in an examiner to deal with subjects like history and literature. He must have an eye for the cardinal points, and must know how a student ought to hold things together in his mind. If he yield to the temptation which seems to beset examiners of picking out "things not generally known," and minute details which a wise man is content to leave to be looked up when he wants them, then a kind of artificial knowledge, solely for use in examinations, will be engendered. In this class of subjects the profit obtained by the student is not proportionate to his recollection of what he has learned. and yet it is this recollection only which can be accurately measured. A student may have got good from his reading, and yet be able to do little even in a paper that is well set; because for an examination the subject must not only be read, it must be "got up."

The studies, on the other hand, which enable one to "do" something supply a power that is always at hand. A classical scholar can at any moment translate a passage. This difference is very important. "Information subjects" burden the memory and give rise to "cram" more than the others; besides, a faculty cannot be lost in a few months and information may. The more, therefore, that a competitive examination can be made to turn on "faculty subjects" the better. Information subjects can be dealt with more satisfactorily when competitions, which should be confined to an early age, are over, and the student is fitting himself for the work of life. He will read them most profitably when he feels that he wants the information, not for display, but for practical use.

Examinations, of course, tell us little directly about moral qualities; industry, indeed, they reward, but the work produced may have been done under the strong incentive of eagerness for success, or under compulsion, or in the absence of temptation, and under other circumstances the candidate's zeal may flag. Energy and tastes go far to make a man what he is, and of these examinations tell us nothing. A *course* of examinations tells something more as to steadiness of purpose and growth of mind than a single one; and a person who follows up an unusual kind of study—such as till lately natural science was—has probably a genuine taste for it.

It makes all the difference to the teacher whether the examination is subordinate to the teaching, or the teaching to the examination. In the first case he is really the educator—he lays down the course he thinks best. In the second he carries out a course which may leave him no option; and even if it embrace alternative subjects, these must often be chosen for the marks they will bring in the time allowed rather than for the good they will do the pupil. On the other hand, if a teacher's work is not subject to some external test, he may get careless, and neglect to keep himself abreast of the progress of science and of the art of teaching. Of course no public advantages could be granted to a certificate given to candidates by their own teacher, when his interest lay in getting them through. If he were independent, like an authorized public teacher, he might be trusted, but he would then be a permanent examiner, and his style would soon be understood. There must, however, be some correspondence between the teaching and the examination, especially on subjects which can be treated in different ways. If a professor, for example, occupy himself with the textual criticism of a book, and the examiner ask no question on this, students will neglect the lecture. Hence, the public teacher should be in communication with the examiner, or form one of a body of examiners.

In Germany the difficulty is solved in this way. At the "abiturient" examination the teachers in a gymnasium propose two questions in each subject; of these the Government inspector chooses one, and this the candidates who are leaving for the university answer on paper. The errors in the answers are marked by the masters, and the papers so marked are considered by the inspector, who, along with the school authorities, and with some reference to the pupil's work in school, decides on his fitness for leaving the gymnasium.

The two functions of testing acquirements and of directing and stimulating instruction do not act always along the same lines, and the examiner and teacher may therefore pull different ways. If the examiner wants to pick out the sharpest lad in a school he will give great weight to anything that shows brilliancy. Excellence, too, in any one department is a far better sign of power than mediocrity in many. But the teacher does not want the clever boy to rely on his facility in Latin verses or to give himself up to his favorite study, and will make the examination turn on the general school work. He will set questions in the parts of the subjects which involve drudgery, in order to enforce attention to them. Propositions in Euclid and questions on elementary grammar may have no effect in discriminating between two clever boys; yet these questions must be set if Euclid and grammar are to be learnt.

Again, an examiner may only want to see that the candidate has a certain knowledge, namely, that which is required in the situation in prospect. He may want to see, for instance, that arithmetical questions can be worked correctly; if this can be done he may not care how the knowledge was got,—all he wants being the fact that it is there. But a boy may be taught to do sums by the old mechanical rules, and this kills the reason instead of developing it. The educator is teaching the boy by means of Euclid, arithmetic and the rest, rather than teaching him Euclid and arithmetic for their value as possessions. He will therefore frame his paper so as to show that the boy has gone through the processes of study which he wants to encourage; his questions will involve principles. His paper may not gauge powers of computation so well as one containing a number of intricate sums to be done in a short time, but it shows whether the boy in learning arithmetic has used his brains.

Examinations are effective in three principal ways as regards education. First, they act as stimulants, partly by holding out the prospect of advantages of some sort, and partly by appealing to the combative spirit in human nature and the desire to excel. Stimulants are valuable in our pharmacopœia, though liable to be used too freely. Youths who might sink into inertness are often roused to vigor by seeing a definite object to work for, or by finding themselves engaged in a contest. On the other hand, if the idea of gain is presented to young people too early, it may over-ride all other motives, such as duty and regard for authority and desire to learn. To those who have been habituated to examinations, it seems useless to work for anything in which they are not going to be examined, and the examinations will not act as a stimulus unless something is to be got by them. Hence competitive examinations should not be often repeated; a single comprehensive one at the end of a long course may do good, but it must not be kept always immediately in view. The pupil should not himself study examination papers, or speculate on the most profitable course, but should trust to his tutor, who will tell him that the best way to get marks is to learn honestly, as if for learning's sake alone. The stimulating effect of examinations leading to gain acts on parents and on schoolmasters. It leads parents to exert themselves to procure, not the best education for their sons they can, but the most direct preparation for competitions. This fosters low notions of education: people overlook the value of developed faculties and good mental habits, and seem to think that if there were no examinations their sons would want no schooling. Often it is of great importance for a youth to pass an examination when there is no time for him to get genuine knowledge; this knowledge must then be simulated by a process called "cram," which means that the "portative memory," or carrying power, must serve as a make-shift for all other faculties. Schoolmasters find a zest given to their work by looking to the places their pupils may gain, but the course which will earn the best place is not always that which will be the best for the youth in the end; and then the master is pulled in the wrong direction by the eagerness of the boy or his parents, and sometimes of his own subordinates, all of whom look first to success. Masters, let it be said, for the most part resist nobly, and aim at doing real good; but the pressure put on them adds to the wear and tear of their work.

Secondly, examinations serve as guides. A youth may seem to be listless only because his energies have not been turned into a definite channel; when he is shown his work, and is started in the way to do it, he becomes quite another being. Besides, a good examination shows what is meant by knowing a subject. The pupil or even a teacher by looking over a thoughtfully drawn up paper of questions gets a higher standard of knowledge; he sees the way of dealing with the subject *secundum artem* as opposed to any slipshod easy-going way of handling it. On the other hand, examination papers which are so meagre that the pupil finds no call on him for intelligence, or in which he can pass by doing a very small portion of the paper, have a most injurious effect. They give the pupil a low view of knowledge, and cripple the teacher, because the pupil is confident of passing with what he thinks he can learn in a week or two before the examination.

Thirdly, examinations oblige a person to be able to produce his knowledge, and encourage him to bring it out in a terse and lucid style. They give no credit to loose or floating knowledge. Notions that are in solution are not available; they must be crystallized in definite form before an examiner will accept them. Great difference is also made between an answer which is perfect and one which is not; and this exerts a good influence, for one of the commonest defects of loosely trained minds is that they are very deficient in exactitude, and do not appreciate the enormous difference between going "somewhere near" the mark and hitting the precise point.

But examinations, even when well conducted, have ill as well as good effects. They destroy spontaneity. Nine young people out of ten may quite rightly be made to move in a good "regulation groove," but the tenth would be better for having room to expatiate. The candidate who is getting up his books is busy about learning, not in thinking. If independent thoughts suggest themselves he puts them aside; his business is with his "books," for his own thoughts cannot be set. This tendency may be obviated by allowing scope in the answers for some discursiveness (but this has its evils also) or by introducing essays, but a man's mind no doubt becomes "examination bound" if he is subjected to repeated definite mechanical examinations. He is kept in a state of pupilage, and only reads to recollect when he is of an age to reflect, to examine, and to judge.

This leads to the question of age. Examinations, though good for boys, are bad for men. Those which deal with general education should not be continued beyond the age of 22. Professional examinations, or examinations in the highest parts of science, intended for those who mean to give their lives to study, must come later, but should be as little competitive as possible. By a "competitive" examination is meant one in which a candidate is depressed or excluded by the superiority of another.

Another point is the strain on the mind produced by competition. This strain is much greater, as has been said above, when many "information subjects" have to be carried in the head at once, than when the pupil has only to exercise in his examination a power which he keeps about him; because, in the former case, he is constantly harassed by the fear that he is dropping something. It is bad for a student when he is interested in his chemistry to feel a panic about his English literature. Nothing wears out the mind so much as being pulled many ways at once, especially if this state of distraction is prolonged. Yearly trials, for instance, for some appointment, a new subject being now and then added to increase the candidates' weight of metal, so habituate the mind to an artificial stimulus that pupils become incapable of studying without it. They can feel no interest in a subject if it is not to be set in an examination; and in time their power of attention is weakened, and their minds become like india-rubber bands which have been too long on the stretch. On the other hand, young people may be expected to be equal to one great effort or perhaps to two. Such occasions may call out some heroism or self-denial, and these qualities are much needed. But for this purpose the teacher should regard the examination with respect, and teach his pupils to respect it—he must not help them to outwit the examiners. In this view it is well that the teachers should have some influence in framing or altering the examination scheme. They will then regard it as in part their own. Moreover, the pupil should have the examination in view at the end of a long vista of study; the preparation for it should not be hurried. The feeling of being short of time adds to worry, and prevents good work.

There are always some students of an anxious disposition who will over-fag themselves at the approach of an examination. This is more frequently the effect of over-worry than of over-work. It will usually be found on inquiry that the hours of work *per diem* have not been excessive; but the evil is that they have had no rest. When not at their books they are letting their minds run on their work, fancying they are forgetting something,—they are haunted by the idea of the examination, and become physically unfit for it. But we must not throw the blame of the mischief that may thus accrue to them on the examinations. Such cases do not commonly occur among those who are aiming at the highest places, and are most exposed to the strain of competition; very often the sufferers are merely pass men, and they are in fact unequal to any call on their nervous energies. The examination is the first call they encounter, and their weakness is shown in that; but they would probably have been in the same condition the first time they were called on to face any responsibility, such as to make a speech, or preach a sermon, or write an article by a given day. After an examination or two this nervousness is overcome by the stronger sort. No doubt young men have to encounter a severe strain at some examinations, and this should be reduced by lessening the load on the memory at one time. It may be very desirable for young men to learn something of six or eight subjects, but they should not be examined in all at once. It is also desirable that those who are exposed to strain of any kind should be under the eye of one who knows the laws of mental and physical hygiene—who can detect the first symptoms of morbid anxiety, and will have authority enough with the pupil to enforce exercise, proper diet, and mental relaxation. If the mind cannot rest, it must have a change of occupation.

The most important examinations are those which lead to university emoluments, and those by which candidates are selected for the civil service and the army.

A clever youth, destined for the university, is at present subjected to examinations from the age of 14 to 23 or 24. First he is brought on at a preparatory school, to compete for a scholarship at one of the large schools. The credit of his schoolmaster is involved in his success, and great pains are taken with the candidates. Usually the examiners understand boys, and the papers are set with judgment; but a boy at 14 should be extending the roots of his knowledge, not arranging it for display; and if he be trained in order to have something to show, there is a danger that solidity may be sacrificed to the early production of results. An examiner taking a school unawares, and questioning the boys, would probably detect the cleverest without doing any harm; but when boys work up to papers, even if they are carefully set, there is a danger of their developing the fatal facility of remembering words with little care for ideas, which belongs to their age. It is said that those who are elected scholars often seem to fall off at first. They have worked under pressure, and the pressure is removed. They most commonly, however, rally for the next contest, which is that for open scholarships at the university. The examinations for these are now almost always in special branches of knowledge,—classics, or mathematics, and natural science. The colleges too often aim at securing, not the youth who is well educated all round, but one who is likely to obtain a high degree in a school of university honors. They want men of power; and *special* distinction is held to be the best criterion of this. Schoolmasters often grieve over the necessity of having to put a boy apart to be prepared for the classical or mathematical market; but the public looks in the newspapers for notices of scholarships gained, and a school which may do admirable work with the staple of its boys will yet be carped at if wanting in university success. Boys are hawked from college to college till they find one which will give the price,—that is to say, a scholarship of the value which the parent or master thinks the boy ought to fetch. Of these youths many have little taste for things intellectual, but they have hard heads, and a keen desire to get a scholarship, without which their friends will not send them to the university. By diligent work they may get such a place in a class list as can be won without special ability. Some, of course, are of a higher order, and of a perfectly satisfactory description; and others, on the withdrawal of the pressure that was on them at school, or under their tutors, turn idle and disappoint their purchasers.

At Cambridge, unless the students are at Trinity College, the "tripos" brings their examinations to an end. At Trinity College and at Oxford an examination by the college is held for fellowships. There are thus two systems for awarding these,—that of special examinations, and that of being guided by the university honors obtained. It is in favor of the first that it gives two or three chances, and that, by affording a long period from the first admission to the university, it enables a young man to retrieve himself if his early education has been mismanaged by his friends. In some cases, too, very good work is done in the intervening years, but for this to be the case the candidate must not be anxious about the examinations. Those who profit in this way are those who may reckon pretty certainly on success. Against this special examination it is urged that it retains men in pupilage up to 24 or 25, that with many it is a question whether their chance is worth the investment of the time, and that it gives an advantage to the richer men who can study at leisure, while the poorer must support themselves at schools or by private pupils.

We now come to Government competitive examinations, such as those for the army and civil service. The object of the system was twofold. First of all it was desired to get rid of patronage, with the solicitation and trouble attending it, and, secondly, to secure the ablest men which the situations can command. The first object, no doubt, is attained, and is well worth attaining; with regard to the second, experience seems to show that the system answers quite satisfactorily for the army, and moderately so for the civil service. The reasons of the difference are that the pay in the army is not sufficient to attract those who have no turn for the profession, or who are deficient in the traditional qualities or bearing of the British officer. This examination also is the less distracting of the two, because the number of subjects that may be taken up, both in the case of the ordnance corps and of the line, is limited, and a preponderance is given to those subjects which furnish faculties over those which result in information. If by these examinations we had to pick out 10 men out of 500, the mechanism would be too rough for the purpose; but if we have to take 50, we get down to the great plateau of mediocrity, where we find a batch of candidates nearly on a level; and even if the sixtieth man were to be a trifle better than the fiftieth, either of them would be good enough for the purpose.

The English Government encounters a particular difficulty in such examinations, because there is no uniform national system of education as in Prussia, and advantage must not be given to particular schools. This makes it necessary to allow a wide option of subjects, and the result is that candidates will take, not what is best for them to know, but what will bring most "marks" within a given period of study. The tutor has to invest the pupil's time in that study which promises best for his score. This is not satisfactory to the educationalist, but as a fact, if these youths were not getting up their modicum of zoology or electricity, they would probably be doing nothing better. The money value of an Indian appointment attracts many youths of a different class from those who seek for commissions; these may be wanting in the qualities which are required to command the respect of Hindus, and they may regard their career too narrowly as an investment of brains and labor for which they expect a good return. Physical accomplishments might be allowed to carry some weight, and be required as a qualification.

The next class to be considered are "pass examinations." These are important from the large number of men they affect. By a pass examination we mean one in which the leading object is to ensure a certain standard. It does not follow that some credit may not be obtained by doing well; indeed, for the healthy operation of the examination it is desirable that those who pass should be classified alphabetically in three or four classes. The objects of a pass examination are to sift out incapacity, and to ascertain that the candidates have gone through a certain process of education. The pass examinations of universities, both in England and France, were until lately framed on a wrong principle. It was thought that the examinations should comprise a specimen of every kind of knowledge that an educated man should possess. If the graduate should prove ignorant of any such branch, the university, it was thought, could absolve itself from responsibility by showing that he had known it at one time. Now, however, we recognize the fact that these scraps of knowledge soon disappear. The portion of chemistry or history which the candidate has passed in is often only so much "book" learnt almost by heart; with those who do really well the case is different. The value of these examinations is only that they show that men can apply their minds, and can express themselves passably well. The subjects should be chosen much less for their value as information than for their requiring the exercise of thought. Pass men are apt to reduce all they can to the action of memory; hence subjects should be taken which require something more than memory. To detect "parrot-work," the examiners should be familiar with the text-books from which the subjects are learnt, and therefore such examinations should be in connection with set courses of teaching. Translation of unseen passages, in Latin for instance, should be insisted on, but a dictionary might be allowed. Questions in geometry should be set in such a way that they cannot be answered by writing out Euclid by heart.

The difficulty of a pass examination depends both on the number of compulsory subjects it contains, and on the standard maintained in each. Feeble men can get through an examination in one or two subjects at a time, if the standard be moderate. Thus an examination which can be passed piece-meal, like the Cambridge "Little-go," is a poor criterion of brains, while an examination embracing many subjects ensures a certain strength of head, but not lasting knowledge of any one thing. When an examination has to be extemporized in order to ascertain whether candidates have heads on their shoulders, it will be sufficient to read over to them once or twice some short narrative or argument, or a correspondence on business matters, and to call on them to give an account of it on paper. This will test sufficiently well many of the qualities which go to make an efficient subordinate.

It remains to say something as to practical methods of examining. Originally examinations were conducted *viva voce*, and they still are so in part. Examinations in experimental philosophy and natural science are valueless without something of the kind. The student must perform experiments and explain them, and must identify and describe specimens. *Viva voce* examination is not well adapted for discriminating between candidates who are nearly equal, because they have not the same questions put to them, and nervousness is a disturbing element. The value of *viva voce* lies chiefly in detecting shallow knowledge. It convicts an impostor. On paper a candidate may avoid a searching question; in *viva voce* he has no escape. The objection to its employment is its great expense. It requires very skilled examiners, two of whom ought to sit together; and the examination should last a quarter of an hour for each man. When the numbers are large this involves a long period of examination and great cost. The German system of giving only one question in each subject for a pass examination, and allowing plenty of time, but requiring a very full and perfect answer, is well suited for fairly prepared men, who have only to be roughly classified as "excellent," "good," "fair," and "indifferent." This forces the candidate to study the whole subject carefully, while if a dozen questions are given, as in England, candidates will speculate on passing with a knowledge of only half the subject.

Essays may be used in examinations in two ways. Subjects of a general nature, like a maxim or topic of the day, may be proposed, in which case readiness and fertility of ideas are tested, but a kind of superficiality and glibness is engendered; or the student may be required to write on some subject belonging to his course. The classical student, for instance, might write on a point of Greek history. A dissertation written at leisure is an excellent means of judging of qualifications, and may be used for those who are past the proper age for examination.

In marking a paper the examiner distributes his marks to the questions according to the difficulty or the time they take to answer. The aggregate of the marks may not coincide with his impression, and it may be well to keep back one quarter of the marks, to be allotted afterwards, according to the impression obtained when the papers are read over again, not question by question, but as wholes. It may be well sometimes to use negative marks, as an answer may reveal such ignorance as to show that some of the correct answers were "parrot-work." When different subjects are compared, a little knowledge should go for nothing, and excellence should count for much. It is a good plan to add to the marks got the excess above half the full value assigned to the paper, and then deduct one quarter of the full value, *e.g.*, if the full value be 500 and the candidate obtain 400, his score will stand thus:—

$$400 + 150 - 125 = 425.$$

Candidates for honors may be arranged in order of merit, as is common at Cambridge, or alphabetically classed, as at Oxford. In the first case brackets should be used, so as to class as equal those who fall within certain limits of uncertainty. These limits will be wider where there is room for difference of opinion among the examiners, as in composition or philosophy, than in mathematics. If the candidates whose marks differ by as much as twelve per cent. are bracketed together, we come to something like an alphabetical arrangement in classes. When the alphabetical system is adopted those who are sure of a first class are freed from anxiety. But many are in suspense about their class, and the difference between being in a first or second class alphabetically arranged is greater than that between being last in the first class or first in the second class, where the lists are in order of merit.

Out of 1000 young men who come to a university with a view to taking a degree, we find from experience that, roughly speaking, the following proportions will hold good:—250 will have both good abilities and the requisite power of will, and will take creditable honors; about 200 more will be comparatively weak in one or other of these qualifications, but may still get a place in an honor school or tripos; the next 150 will be the more vigorous pass men, who will show intelligence in subjects of but moderate difficulty, will enter keenly into the life of the place, and will pass their examinations respectably; 200 more will pass without failure; the 100 that follow will meet with failures more or less frequently; and the remaining 100 will never pass any university examination at all. Some of these last instances may almost be regarded as cases of disease, arising from infirmity of will or the want of the power to fix the attention. Neglect of the early acquisition of good mental habits is the cause of many failures. A youth may be rejected once from love of amusement or from underrating the examination, but he does not fail again if he can help it. A second failure shows moral or intellectual incapacity.

On this subject see—"Remarks on State of Education at Cambridge," in Dr. John Jebb's works, 1774 (here we find the first plan for examining the pass men); Peacock, *On the Statutes of the University of Cambridge*, 1840; Whewell, *Of a Liberal Education*, 1848; *Reports of her Majesty's Commissioners on Oxford*, 1852, and *on Cambridge*, 1854 (in the latter see the evidence of Dr. Philpott, Prof. Stokes, Dr. Merivale, Mr. R. Leslie Ellis, and Mr. W. Hopkins); *Suggestions on Academical Organization*, Mark Pattison, B.D. (referring to Oxford); L. Wiese, *German Letters on English Education*, translated by L. Schmitz, 1877; *Education in Oxford: its methods, its aids, and its rewards*, James E. Thorold Rogers; *Conflict of Studies*, I. Todhunter, F.R.S., 1873; *Higher Schools and Universities in Germany*, M. Arnold, 1874; *On the Action of Examinations*, H. Latham, 1877; *Report to the French Government on Education in England*, by M. Demogeot and M. Montucci, 1870; *Third Report of Royal Commissioners on Scientific Instruction*, 1873; M. Burrows, *Pass and Class*, Oxford, 1873; *Student's Guide to the University of Cambridge*, 1874; *Twentieth Report of Civil Service Commissioners*, 1876. Sayce; *Contemporary Review*, April, 1876, "Idle Fellowships," H. Sidgwick, and November, 1877, "The Civil Service Examination Scheme in relation to Sciences and to Languages," Alex. Bain, LL.D.; *Nineteenth Century*, April, 1878, "The Good and Evil of Examination," Canon Barry; *Quarterly Journal of Education*, April and July, 1872, "On the Leaving Examinations of Prussia," by W. C. Perry; *Macmillan's Magazine*, June, 1877, "On German Schools," W. C. Perry, and March, 1878, "German Views of Oxford and Cambridge." (H. LA.)

EXARCH (ἔξαρχος, a chief person or leader), a title that has been conferred at different periods on certain chief officers or governors, both in secular and ecclesiastical matters. Of these, the most important were the exarchs of Ravenna, the first of whom was appointed by Justinian, emperor of the East, as governor of the middle part of Italy, which was made a province of the Eastern empire after Narses had entirely subdued the Goths and their allies in Italy, 552–554 A.D. Ravenna, with the whole exarchate, was conquered by Astolphus, king of the Lombards, in the year 752; but three years later it was taken by Pepin, king of the Franks, who bestowed it on the pope (Stephen III.), from which time Ravenna and its territory remained united to the papal dominions. The exarch of a diocese was anciently the same as primate. This dignity was intermediate between the patriarchal and the metropolitan, the name patriarch being given only to the heads of the more important dioceses. Metropolitans are also sometimes called exarchs, but apparently not in a technical sense. Exarch is used, in the ecclesiastical antiquities of the Eastern Church, for a general or superior over several monasteries, and is also applied to certain ecclesiastics deputed by the patriarch of Constantinople to collect the tribute payable by the church to the Turkish Government. In the modern Greek Church, an exarch is a deputy, or legate *a latere*, of the patriarch, whose office it is to visit the clergy and churches in the provinces allotted him.

EXCAMBION, or Exchange. Excambion (a word connected with a large class of Low Latin and Romance forms, such as cambium, concambium, scambium, from Latin *cambire*, and Greek *κάμβειν* or *κάμπτειν*, to bend, turn, or fold) means in Scotch law the exchange of one heritable subject for another. Its meaning is extended by Lord Stair (*Inst.*, i. 14, 1) to every case of exchange or barter, the *permutatio* or innominate contract (*Datur res ut vicissim res detur*) of the civil law, about which a fierce controversy raged between the Proculian and Sabinian schools, as to whether it was truly a sale or a separate contract. Both schools used to quote the words of Homer, "And thence, too, wine was got by the long-haired Achæans, some bartering it for bronze, and others the glistening steel, some hides, and some the cows themselves, and some again slaves." This Roman contract was not constituted by consent, but by a formal stipulation; it did not pass the property of movables, if the seller had not a title; and it was liable to be rescinded on proof of great inequality. In each of these features it has been modified by the modern law of most European states. Erskine says (*Inst.*, iii. 3, 13), "This doctrine (of property not passing apart from title) may be equitable if directed only against the party himself and his heir; but there could be little security in the commerce of movables if it were extended against a singular successor who had *bona fide* bought the subject from the party after the exchange." In other points, such as the risk of a subject being destroyed, or the remedies on breach of contract, permutation of movables falls under the same rules as sale. The feudal lawyers amused themselves by discussing what name should be given to a contract in which the consideration consisted partly of money. They called it sale where *major pars in pretio quam in re permutata.* In the more limited sense of the exchange of heritable subjects, this contract received from the feudal law some advantages not given to sale. Thus, the burdensome right of the superior called *protimesis*, or pre-emption, did not apply to excambions. The *decuriones*, or town councils, of the imperial *municipia* were allowed to excamb, although they could not sell, the town lands; and so with regard to church lands, the *fundus dotalis*, and other subjects partly withdrawn from commerce, excambions, but not sales, were permitted. Sovereigns, too, were allowed to excamb parts of the royal domain, although, as may be seen from the Scotch annexation and dissolution statutes of the 16th century, it required special authority to feu or alienate such subjects. The modern Scotch excambion may consist in the exchange of any heritable subjects whatever, *e.g.*, a patronage or, what often occurs, a portion of a glebe for servitude. The older form of an excambion was in separate dispositions by each "copermutant," as Pothier calls him, in favor of the other, or sometimes mutual charters, each party becoming in turn vassal and superior. And according to the *Leges Bergorum*, c. 55, where lands or houses in burgh were exchanged, the form of delivering sasine consisted in the *apertio* and *clausio* of the door, or the passing out and in of the parties respectively, each of whom gave two pennies (*duo nummi*) to the bailie. But this early form was soon superseded by one contract of excambion (originally drawn by Gilmour and Nisbet, and preserved in the MS. Style Book of Bain of Pitcarly) containing both dispositions, and proceeding generally on the narrative that the parcels of land excambed lie remote from or at least discontiguous to the mansion-house or the principal estate, and, being intersected by the lands of the other party, form a run-rig possession. This contract gives to each party a sufficient narrative of his own title to the lands he is disponing, and it provides, although the law implies this in every express excambion, that on eviction the contract and sasine shall be void and null, and that immediate "recurrency" or regress be given *brevi manu* to the lands which were excambed by the party evicted. Such real warrandice, as it is called, affects excambed land in the hands of singular successors who have purchased *bona fide*, and hence it is often provided that notice of any action of eviction shall be given to the excamber or his heirs. This exceptional severity reminds one of the civil law which distinguished between sale, where delivery of possession with warrandice against eviction was sufficient performance by the seller, and exchange, where an absolute title of property must be given. Writing, however, is not, by the law of Scotland, essential to an excambion. Chiefly in favor of the class of cottars and small feuars, and for convenience in straightening marches, the law will consider the most informal memoranda, and even a verbal agreement, if supported by the subsequent possession. The power to excamb was gradually conferred on entailed proprietors. The Montgomery Act, which was passed in 1770, to facilitate agricultural improvements, permitted 50 acres arable and 100 acres not fit for the plough to be excambed. This was enlarged by the Rosebery Act in 1836, under which one-fourth of an entailed estate, not including the mansion-house, home farm, and policies, might be excambed, provided the heirs took no higher grassum than £200. The power was applied to the whole estate by the Rutherfurd Act of 1848, and the necessary consents of substitute heirs are now regulated by the Entail Amendment Act of 1875.

Exchange, in English law, is defined as the mutual grant of equal interests, the one in consideration of the other. The peculiarities of this very ancient common law conveyance or assurance were—(1) equality of estates, not in value or in subject matter, but in legal right of ownership; (2) the use of the word exchange (*excambium*, *e.g.*, in Domesday book, *hanc terram cambiavit Hugo, etc.*); (3) that, though formal delivery of seisin was not required, possession or entry was required to complete the transaction by making it notorious; (4) that, in the case of incorporeal hereditaments, and where the lands lay in different counties, a deed was required; (5) an implied condition of re-entry on the lands of him whose title failed (Coke on Littleton, 50 *a;* Blackstone by Sweet, ii. p. 323), the liability to re-entry affecting an alienee, but the right to re-enter being personal to the exchanger and his heirs. This condition, however, did not long survive the statute *Quia emptores;* and exchanges are now generally effected by mutual conveyances with the usual covenants for title, which the Act 8 and 9 Vict. c. 106 declares not to imply any condition, whether the word "exchange" be used in the *testatum* or not. Exchanges are also very frequently made, by order of the inclosure commissioners, under the various Acts of Parliament for the inclosure, exchange, and improvement of lands, from 8 and 9 Vict. c. 118 to 31 and 32 Vict. c. 89 (see Cooke *On Inclosures*). In these cases, the property taken is simply impressed with the title of the property given in exchange. So also statutory exchanges are made under the Acts for the Sale and Exchange of Charity Estates, the Charitable Trust Acts, from 16 and 17 Vict. c. 137 to 32 and 33 Vict. c. 110, which now apply to Roman Catholic charities, formerly under 23 and 24 Vict. c. 134. There are also statutes enabling ecclesiastical corporations to exchange, with the approval of the church estate commissioners. Powers of exchange are generally given to trustees under English settlements, and these are exercised by revocation of the original uses and appointment of new uses, all ancillary powers being given by implication under 23 and 24 Vict. c. 145 (see Davidson's *Precedents in Conveyancing*, vols. ii., iii., and v.).

In what may be called international conveyancing, the exchange of territories is accomplished by treaties, of which there is no fixed style. A well-known example is Art. XII. of the Treaty of Nimeguen. "Les terres enclavées seront exchangées contre d'autres qui se trouveront plus proches et à la bienséance," etc. The Italian duchies and islands have very frequently been exchanged. Thus, in the Quadruple Alliance of 1720, Philip V. exchanged a reversionary title to Sicily for a reversionary title to Sardinia. The exchange of prisoners in war is often regulated by documents called cartels, which specify a certain agreed-on value for each rank of prisoners. The transference of prisoners is often carried out by cartel ships, which, though prohibited from carrying cargo or passengers, are entitled to certain privileges. It was in the 17th century that this practice (which seems to have been unknown to Grotius) superseded the older one of ransom at the end of the war.

See Wheaton's *Elements of International Law*, Lawrence's edition, p. 590, and App. A. in Robinson's *Adm. Rep.*, vol. iii. The early law of military exchange will be found discussed by Albericus Gentilis, *De Jure Belli*, cap. xvi., "De permutationibus et liberationibus." (W. C. S.)

EXCHANGE. The system by which commercial nations discharge their debts to each other has been termed "Exchange," or "the Exchanges." It has been a subject of much study both by merchants and bankers who have to deal with its phenomena in the course of business, and by economists desirous to discover the causes of the phenomena, and to explain the laws or method of their operation. In rude times the people of neighboring countries brought their staple or surplus produce to common fairs, where one kind of goods was valued and bartered for another; and the dealers brought a little gold and silver with them to settle the small balances. But this, though a rough type of international trade still, is a wholly different affair from modern commerce, with its transactors multiplied a millionfold, and conducting their transactions far apart in widely distant countries. Money itself does little to obviate the difficulties arising from this multiplicity of crossing and recrossing currents; and whoever, therefore, was the first introducer of the idea of "Exchange" is entitled to a high place in the commercial annals of the world—whether it was the stranger mentioned by Isocrates, who came to Athens with some cargoes of corn, and gave an order on a town on the Euxine where money was owing to him, with recourse on an Athenian merchant in the event of the order being dishonored; or Cicero, in paying for the studies of his son at Athens by an assignment from a creditor in Rome on his debtor in the Greek city; or the pope, whose lending merchants of Siena and Florence drew upon Henry III., or rather on the prelates and abbots of England, with some English merchants as remitters, for the expenses of deposing Manfred, king of Sicily, in which act of deposition Henry was an interested and obligant party—thus avoiding in these various cases the difficulty and risk of transporting coin. The idea, wherever first exemplified, was too good to be lost. It was early developed into a system in Venice, later in Amsterdam, and is now of world-wide application.

It is well to observe, first, what is exchanged—values of commodities exported and sold from one place or country to another, debts thereby owing, interest, profits of capital invested abroad, foreign loans and subsidies, freights, banking and other commissions, expenses of foreign residence or travel, and, in short, claims of payment of every kind on one part, having their relative obligations of remittance on the other, and originally denominated, as the contract or the occasion may have been, in the money either of the places from which the claims proceed or of those where they are payable. Secondly, the means must be noticed by which the exchange is effected—pieces of paper, bearing express calculation to secure what is exactly due between debtor and creditor. A bill of exchange is an order drawn for a specified and definite sum, in favor of a person who is the buyer and becomes the "remitter" of the order, upon a third person, the "drawee," who is indebted for this sum to the drawer, and on presentation of the order becomes the "acceptor." The person or company in whose favor the order is drawn may pass it into other hands, and these, by writing their names on the back, become "indorsers." On much the same model there are "inland" and "foreign" bills of exchange. The whole system of exchange has its foundation in the drawing of the creditor on the debtor; for, as in every country there are both creditors and debtors of other countries, the debtors find it to their advantage to take up the drafts of the creditors in order to avoid direct remittances in cash.

Inland exchange.

Inland exchange is simpler in character and more easily comprehended than foreign exchange, but in reality presents the same phenomena and the same sequence of cause and effect as the other, so far as the circumstances of any country allow these to come into operation.

Mr. M'Culloch, in the article on "Exchange" in former editions of the present work, gave a familiar exposition of inland exchange, which it would be difficult to improve:—

"If the debts reciprocally due by London and Glasgow be equal, whether they amount to £100,000, £500,000, or any other sum, they may be discharged without the intervention of money, and the price of bills of exchange will be 'at Par;' that is, a sum of £100 or £1000 in Glasgow will purchase a bill for £100 or £1000 payable in London, and *vice versâ*. But if these cities be not mutually indebted in equal sums, then the price of bills will be increased in the city which has the greatest number of payments to make, and reduced in that which has the fewest. If Glasgow owe London £100,000, whilst the latter only owes the former £90,000, it is clear, inasmuch as Glasgow has a larger sum to remit to London than London has to remit to Glasgow, that the price of bills on London will rise in Glasgow because of the increased demand, and that the price of bills on Glasgow will fall in London because of the diminished demand. A larger sum would consequently be required to discharge a debt due by Glasgow to London, and a less sum to discharge an equal debt due by the latter to the former; or, which is the same thing, the exchange would be *in favor of* London, and *against* Glasgow. Bills on London would sell in Glasgow at a *premium*, and bills on Glasgow would sell in London at a *discount;* the premium in the one case being equal to the discount in the other.

"On the supposition that the balance of £10,000, due by Glasgow, depresses the exchange on London *one per cent.*, it appears, at first sight, that it will cost Glasgow £101,000 to discharge her debt of £100,000 due to London; and that, on the other hand, £89,100 would be sufficient to discharge the debt of London to Glasgow. But a very little consideration will serve to show that this would not be the case. Exchange transactions cannot take place between different cities until debtors and creditors of the one reside in the other. And hence, when the exchange became unfavorable to Glasgow, the premium paid by its merchants for bills on London would not go into the pockets of their creditors in the latter, but into those of their neighbors in Glasgow to whom London was indebted, and from whom the bills were purchased. The loss to Glasgow would, therefore, be limited to the *premium* paid on the balance of £10,000. Thus, supposing that A of Glasgow owes D of London £100,000, and that C of London owes B of Glasgow £90,000, A will pay to B £91,000 for a bill or order on C to pay D £90,000. In this way the £90,000 of London debt at Glasgow would be cleared off,—the premium, which is lost by the debtor to London in Glasgow, being gained by its creditor in the same place. If the business had been transacted in London, C, with £89,100, would have purchased of D a bill for £90,000, payable by A; so that, in this case, the gain would have fallen to the share of the debtor C, and the loss to that of the creditor D, both of London. The complexity of real transactions does not affect the principles on which they are founded. And whatever may be the amount of the debts reciprocally due by different places, the only disadvantage under which any of them could be placed by a fall of the exchange would be the unavoidable one of paying the expense of remitting the *balance* of debt.

"The expense of transmitting money from one place to another limits the fluctuations in the exchange between them. If 20s. sufficed to cover the expense and risk attending the transmission of £100 from Glasgow to London, it would be indifferent to a merchant, in the event of the exchange becoming unfavorable to the former, whether he paid one per cent. *premium* for a bill on London, or remitted money direct to the latter. If the premium were less than one per cent., it would be clearly his interest to make his payments by means of bills rather than by remittances; and that it could not exceed one per cent. is obvious, for every individual would rather directly remit money than incur an unnecessary expense by purchasing bills on London at a greater *premium* than would suffice to cover the expense of a money remittance. If, owing to the badness of roads, disturbances in the country, or any other cause, the expense of remitting money from Glasgow to London were increased, the difference in the rate of exchange between them might also be proportionally increased. But in every case the extent to which this difference could attain would be limited by, and could not for any considerable period exceed, the cost of remitting cash.

"Exchange transactions become more complex when one place, as is often the case, discharges its debts to another by means of bills drawn on a third place. Thus, though London should owe nothing to Glasgow, yet if Glasgow be indebted to London, London to Manchester, and Manchester to Glasgow, the latter may wholly or partially discharge her debt to London by remitting bills on Manchester. She may wholly discharge it, provided the debt due to her by Manchester exceed or is equal to the debt due by her to London. If, however, it be not equal to the latter, Glasgow will either have to remit money to London to pay the balance of debt, or bills on some other place indebted to her.

"Transactions in inland bills of exchange are almost entirely conducted by bankers, who charge a certain rate per cent. for their trouble, and who, by means of their credit and connections, are able on all occasions to supply the demands of their customers. Bills on London drawn in Edinburgh and Glasgow were formerly made payable at forty days' date, which was equivalent to a *premium* of about ½ per cent.; but, owing to the greater facility of communication, this *premium* is now reduced to twenty days' interest, or to about $\frac{1}{4}$ per cent. Bills for remitting the revenue from Scotland are now drawn at thirty days; previously to 1819 they were drawn at sixty days.''

The cost of remittance from Scotland to London has continued to fall during the last thirty years. Bills on revenue account are now drawn at eleven days, free of stamp, and bankers' drafts at seven days, or at a charge of 2s. per £100 up to £300, 6s. for all sums between £300 and £600, and 1s. additional for every £100 above £600. On the other hand, the London bankers remit money, paid over their counters to-day, to Scotland and other parts of the kingdom, payable at par to-morrow. To this extent the rate of exchange is still adverse to Edinburgh and Glasgow, and in favor of London. In like manner the holder of a bill of exchange in Edinburgh or Glasgow upon London finds himself in a somewhat better position than the holder of a bill in London upon either of the two Scotch centres. Yet it would be an error to suppose that the balance of trade is against Scotland and in favor of England. The balance of value of commodities exchanged between the two countries is in favor of Scotland, and might be greatly in her favor, and yet the rate of exchange be adverse; so that we are thus early admonished that the imports and exports of goods, though an important, are not, as was long supposed, a decisive element in the rate of exchange. The transmission of the revenue of Scotland (seven or eight millions annually), the rental of owners of land having their chief domicile in the metropolis, and the amount of obligations of Scotch merchants made payable in London under the increasing concentration of monetary business, would be sufficient to counteract the effect of a large balance of trade on the rate of exchange. Hence London bankers, in taking money even in small sums payable at par next day in Edinburgh or Glasgow, are simply taking beforehand what is already under course of remittance, and reducing *pro tanto* the balances to be remitted from Scotland.

The relations of inland exchange just stated are those of a country where the money is uniform; where the bank-notes of Ireland and Scotland are payable on demand in the common imperial standard of value, as the country bank-notes of England are similarly exchangeable for gold or for Bank of England notes, which latter are orders for the delivery of so much gold in the issue department; and where, consequently, all inland bills are drawn in precisely the same money. The circumstances are thus highly favorable to an even exchange; and it may be conclusively held that the nearer the monetary system, whether in separate countries within themselves, or in nations closely related by commercial and financial transactions one with another, approaches to these conditions, the difficulties and oscillations of exchange, inland and foreign, will be reduced within narrower limits.

The history of inland exchange in the three kingdoms presents abundant proofs of the immediate effect of money of differing values in disordering the exchanges, or, in other words, the uniform payment of their debts one to another. In the early days of Scotch banking, when the natural limit of a free legal issue of notes was less understood than it soon became, and a structure of bills of exchange was reared upon this basis, it was found that bullion had to be raised by constant re-discounts in London, and that exchange, in short, became impracticable. Even within the same town, given two kinds of money or currency, one of superior value to another, a premium will be immediately established in favor of the money of superior value, and will affect every transaction, however small, by calculations of rate of exchange, as was long illustrated by the *banco* of Hamburg, a strict metallic money of given weight and fineness, in its contact with the worn or degraded coins of various mints in prevailing circulation. In 1689, when, by a proclamation of James II., one penny was added to the nominal value of the Irish shilling, £108, 6s. 8d. Irish money became equal to only £100 of British money in the nominal par of exchange between Great Britain and Ireland, or a difference of $8\frac{1}{3}$ per cent. against the latter. In the course of another century the monetary system of Ireland and Great Britain had so far become uniform that the bank-notes of both countries were payable on demand in gold, but the dilution of standard proclaimed by James II. was still in force. In the eight years previous to 1797, the date of the Bank Restriction Act suspending specie payments, the rate of exchange between London and Dublin had ranged from $7\frac{1}{2}$ to 9 per cent., being from $\frac{5}{6}$ below to $\frac{2}{3}$ per cent. above the par of exchange, as determined by the actual value of the British and Irish money. The banks of England and Ireland were now alike free to issue notes without legal liability to pay them in gold on demand; and in 1803 the Bank of Ireland had increased its issues from £621,917 to £2,707,956, being in the proportion of 1 to 4·3; while the Bank of England had increased its issues in the same period from £9,181,843 to £16,505,272, or in the proportion only of 1 to 1·8. The rate of exchange was then 17 per cent. against Dublin, being $8\frac{2}{3}$ per cent. more than the normal par. But in the seven subsequent years the issues of the Bank of Ireland increased at the rate of $2\frac{6}{7}$ per cent., and the issues of the Bank of England at the rate of 5 per cent., while the country bank issues of Ireland were much diminished in amount, and those of England were largely increased. During this period the current rates of exchange became more favorable to Dublin. The inconvertible paper currency of Ireland had increased, but it had not increased in nearly the same proportion as the same kind of money in England. The manufacturers of Ulster, at once disaffected against the Government and annoyed at the uncertain value of the bank notes, clung to a gold currency; and while Dublin was under a discount of 8 per cent. in its exchange with London, Belfast was commanding a premium of 3 per cent. against London, and 10 per cent. against Dublin.[1]

Apart, however, from this element of the differing standards and values of money, which comes more fully into view under the head of "foreign exchange," it is impossible to follow closely the description of inland exchange above quoted from Mr. M'Culloch without apprehending many of the principal characteristics of the operation, which, as they are sure to arise in exchange transactions under all circumstances, cannot be too soon brought into formal notice; such as (1) that the rate of exchange is ruled by the supply and demand of bills for the time being; (2) when in any market the demand for bills on a given centre is greater than the supply, the deficiency may be supplemented by bills on other centres having a favorable exchange with the given centre—a resource which, though indirect, receives much extension in the wide theatre of the commercial world under the watchful study of experts in bills; (3) the profit of a premium and the loss of a discount on bills fall within the market where the bill is drawn or sold, the drawee or acceptor having the definite sum on the bill to pay in either case; (4) exchange between one country or one centre and another is never a completed or perfectly adjusted process, but a constant series of transactions, reflecting the varying phases of claims and debts as they mature; and (5) the fluctuation of rates of exchange is effectually limited by the expense of transmitting money, that is, coin or bullion,—a principle which, though subject to partial exceptions in foreign exchange, is an underlying and potential law of the whole system.

Foreign exchange.

In the study of foreign exchange some embarrassment arises from the two-fold character of the action and its results, and the necessity of realizing in one conception the drawers and buyers of the bills, and the two countries to which their transactions apply. It tends to simplify the matter to remember that what is transacted either in London or Paris expends the whole effect, for purposes of comprehension at least, of the course of exchange between the two cities; and so in other cases. If the debts, the time of settlement of which has come, of London to Paris be greater than the debts of Paris to London, the supply of bills on Paris in London will be less, and the supply of bills on London in Paris will be greater than the demand, which are only different forms of expressing the same relation. There may be a momentary variation in the rate of exchange in the two cities, but as soon as the relation of supply is discovered the variation will disappear. On both fields the same two classes of people, drawers and remitters, are at work, only the party in stronger force on the one is in weaker force on the other, and at both ends there is the same though converse result. In any one market, therefore, there is a complete representation of the action of exchange.

---

[1] The *Bullion Inquiry and Report* of 1819 is full of information and discussion as to the effects on exchange of the long breach in our monetary system during the French Revolutionary wars, which will always be highly instructive, but on which it would here be out of date to dwell. The Scotch banks do not appear, during that trying period, to have departed from the rule of paying their notes in gold on demand. The contrary lesson may have been so well impressed on them by the experience of the previous century, and so well explained by the intermediate instructions of Adam Smith, whom, of course, they were the first to read, as to raise them above temptation.

To a circle of exchange four persons, as is explained by Mr. Mill, are always necessary: A, say of England, has exported English goods to B, say in France; and in order that B may be saved the expense and risk of sending money to A, A draws a bill on B for the sum due, and sells it to his neighbor D in England, in order that he may send it instead of money to C in France, from whom D has imported French goods of exactly equivalent value, and who, on the expiry of days the bill has to run, takes it to his neighbor B, and gets his payment, while in possession of the bill B has his discharge from A. The debt on both sides is thus paid without the transmission of a single ounce of gold or silver.

This is a genuine circle of foreign exchange; but in the great commerce and diversified creditorship and debtorship of the world the process is frequently of a very complex kind. Not only all the exports and imports, freights, and transit dues round the globe, but nearly all the public and private outlays which one country expends upon another, are paid by means of foreign bills of exchange. Mr. Goschen, in a practical treatise which may be said to bring up the science of exchange to the present time,[1] examines the various classes of foreign bills, and specifies some movements of exchange which could hardly be dreamed of save by professional men. For instance, teas shipped from China to New York are generally paid for by a draft of the exporter on a London merchant for account of the American importer. The exporter in China is paid by the price which is given him for his bill on London; and the London acceptor looks for payment to the importer in New York. In the East Indies those who ship produce to America draw on London and not on New York; and the New Orleans cotton exporter to Russia draws on London instead of on St. Petersburg. The explanation of this may be partly that Great Britain exports more in manufactures and silver to China, for example, than she imports of Chinese tea and silk, and thus leaves a balance of trade due to her, which the Chinese pay by transferring their claims on New York to their London creditors, and partly from the greater reputation and custom of the London banking houses than those of New York or St. Petersburg, though many of these may be no less wealthy than the others, or simply from the greater convenience of a bill on London. In proportion, however, as direct trade in mutual import and export of goods is established between two countries, direct exchange follows. Formerly the New York houses drew, for their shipments of tobacco and other produce to Bremen, on England for German account. But now since German manufactures and products have been making progress in the New World, bills of exchange are drawn between New York and Bremen, and Rio Janeiro and Hamburg. But the merchants of Bombay and other parts of India, finding few purchasers of bills on Bremen, still draw on London for German account. These indirect exchanges may be regarded as examples of the common expedient of utilizing both debts and credits at various distant points in redressing the inequalities of direct exchange; and, also, of the advantage of London, from the greater extent of British commerce and the greater distribution of British exports than those of any other country, as the centre for ultimate adjustments and clearings of this kind. But Mr. Goschen has adduced an extensive class of foreign bills still more remarkable. These are bills "technically said to be drawn in blank," which represent no actual indebtedness at the period of drawing, and by which the acceptor does not pay his debt to the drawer, but on the contrary, the drawer incurs a debt to the acceptor. Mr. Goschen admits that they approach nearly to the character of accommodation bills in the home trade, might be even worse abused, and consequently require to be discriminated. In many cases such bills have a function of public utility,—as, for example, where the imports of a country do not fall into the same period of the year as its exports, and the bills in payment of them do not meet each other in the ordinary course. In that case, the importers in seeking to buy bills on foreign countries would not find them, and would have no recourse but to remit specie in payment of their purchases abroad. In like manner the exporters of grain, cotton, and other produce might draw bills for their value, but would find the bills were unsalable, and would have to order the gold, remitted by the importers a few months before, to be sent back again. In this situation banking-houses draw "in blank" on bankers abroad, selling their drafts to importers at one period of the year and buying the bills of the exporters at another, therewith to refund the bankers abroad by whom their drafts have been honored. The case implies a raising of capital in anticipation of the produce, but there need be nothing fictitious either in its manner or character, and it may well be believed to be the case of many large producing countries and colonies. In the dealings of foreign exchange the small as well as the large bills are embraced. With the piles of single bills for many thousands of pounds sterling, from such countries as China, India, or America, are commingled many bills of small amounts; while from all parts of Europe they are of a still more miscellaneous character —bills of retail as well as wholesale trade, bills of Swedish or Norwegian shipmasters for freights, of Dutch and Belgian farmers for parcels of eggs and butter, of Germans for toys, and French for odd *articles de Paris*, on minor agents, shopkeepers, milliners, and others, who may not have come in the course of their business within the range of inland exchange.

The developments of foreign exchange are always more or less modified in the course of a generation, and so much seems necessary as an introduction to the essential subject itself, and in particular to the explanation of the rate of exchange, how it is determined, and what in a general sense it imports.

Mr. M'Culloch, in former editions of this work, treated foreign exchange under three heads:—(1) *nominal exchange*, or the rate of exchange established between two countries on a strict estimate of the respective money, or coins, or currencies, in which the value of their goods is usually denominated and exchanged; (2) *real exchange*, or the effect of the supply and demand of bills in raising the current rate above, or depressing it below, the mean point or equilibrium—nominal, inasmuch as it is an equal value from which there is constant variation by other elements acting on the rate of exchange, but yet of radical fixity and importance; and (3) *computed exchange*, or, in reality, the actual course of exchange as determined day by day from the combined consideration and effects of the other two. While this division was appropriate enough, it may be better here to consider still more in detail the various elements entering into the valution of foreign bills, or, in other words, the rate of foreign exchange. These may be conveniently embraced under the following heads:—(1) par of exchange; (2) supply and demand of bills; (3) rate of interest; (4) cost of specie remittance; to which may be added, what is always implied, (5) correct judgment of the force and duration of the cause or causes affecting the rate of exchange, or its opposite, panic.

Par of exchange.

1. Without some common medium of value in commerical countries, bills of exchange could not be drawn between one and another. The "cash" of China has played no more part in the foreign exchanges than the cowries of Africa; but since a mint has been established in Japan, from which gold pieces are issued under public regulation as to weight and fineness, there may be no difficulty in ascertaining the monetary equivalency, at Yokohama, of any debt due by Japan to England, or *vice versâ*. The nations have thus found a medium of exchange in bullion, in gold or silver, or in both. In countries of the double standard, it has been usual to modify the law by liberty of contract for payment in one of the metals, without which liberty, indeed, it would be as well to have only one standard, since it is certain that the debtor will always choose to pay in the metal that has become relatively cheaper. In countries where silver is the sole standard, the par of silver to gold may be 15 to 1, or 16 to 1, as law or custom may have established; but in foreign exchange the par of silver to gold cannot be fixed at any absolute point by the law of any one country, and in the case of a depreciation, say of silver, even though temporary, by which the market price of silver to gold became 17 to 1, a proportionate addition would be made to the figures of the mint or former customary par, and this new sum become practically the par of exchange between the gold currency of England or California and the silver dollars of Mexico or rupees of India. Thus, having gold and silver to deal with, it is always possible, whatever may be the variety and names of

---

[1] *The Theory of Foreign Exchanges*, by the Right Hon. G. J. Goschen, M.P., ninth edition, London, Effingham Wilson, 1876.

the coins of different countries, to estimate the equivalents of the one to the other. This is a matter simply of weight and assay; and the ratio thus found is the par of exchange between one country and another.

Mr. M'Culloch seems to have thought that the par of exchange should properly include, not only equivalent weight and purity of the precious metals, but their relative cheapness or dearness in given places. "Thus," he says, "if, because of the expense of carriage, the value of bullion in Great Britain be 5 per cent. greater than in San Francisco, 100 ounces of pure gold in the latter would not be worth 100 ounces of pure gold in London, but 5 per cent. less; and the exchange would be at true par when bills for 105 ounces standard bullion payable in San Francisco, sold in London for 100 ounces." Since this has not been the practice in determining the par of exchange—the 25·30 of Paris, and the old 109 of New York, etc., with London having been based more less exactly on equal weights of pure gold for pure gold—a question is suggested which the following considerations may help to resolve. The 5 per cent. claimed from San Francisco is for a relative dearness of gold in London, which can only be overcome by carrying the gold from the one place to the other; but it would be illogical to charge in a bill of exchange for a transport of specie which it is the express object and effect of the bill to supersede. The merchant in London would be entitled to sell a bill on San Francisco for a sum equal to 100 ounces of gold, and to include the cost of exchange, if any; or his debtor in San Francisco might buy a bill on London for a sum sterling equal to 100 ounces of gold; and if the course of exchange were such that this bill cost him only 99 ounces, the merchant in London would yet have no reason to complain. If neither of these modes of settlement were available, the debtor in San Francisco would have to send 100 ounces of gold to London, in which case there would be no rate of exchange in question.

But, apart from the less value of bullion in some countries than in others, owing to nearness to the mines or other causes, there is a cheapness of the metallic money, as well as the general currency of a country, which operates directly on the rate of exchange, and requires in one form or other the recognition of a different par from that established under other conditions. The standard may be tampered with; the alloy may be increased; the weight of the coins may be diminished and diminished, till, like the Turkish piastre, they become scarce a shadow of themselves. It is obvious that innovations of this kind compel a rectification of the estimated par of exchange. In other cases coins are legitimately changed; and these variations, in so far as they supersede or modify coins which entered into the par estimate, are bound to have a new rating. A country which allows its coinage to be much worn, defaced, and generally light in weight, is in the same position as one which has deliberately lowered its standard of value; for though its light coins, when sent abroad, which they are not apt to be, count for no more than they weigh, there is the other and more serious effect that they may have been already well weighed at home, and have so raised the prices of the goods of the country as to place all dealings in them under a delusion as to their real value. One may well believe, however, that this is a form of monetary evil which has now passed away. There will always be some more or less worn and light coins in a metallic circulation, and as long as these are limited in number, and circulate in the country of their coinage at the mint price, they do little or no harm. There is a much more convenient process by which to cheapen the money of a country than any form of debasing the coinage, namely, to dispense wholly or almost wholly with metallic money in favor of an inconvertible paper currency.

Effect of inconvertible paper money.

When a country is impelled to issue paper money not payable on demand in gold or silver, its monetary value slips away from all fixed reckoning. The first effects are so agreeable as naturally to lead to a larger and a still larger issue, and the agreeable effects are prolonged until the real situation begins to be disclosed, and, finally, derangement has spread so widely on all sides that extrication becomes a task of the gravest difficulty. The effects even on the foreign exchanges are for a time somewhat illusive. There being no more need for gold and silver, nearly the whole stock of bullion passes out, and like a new found capital gives ample power of purchase abroad. The importer, finding that there are increasing prices for every commodity in the paper money, goes into his business with new heart and will. The premium, which has early begun to be established on foreign bills, soon becomes so large that the exporter imagines that he can make a fair profit out of the premium on his foreign bill alone, though there may not be a margin of a fraction of one per cent. of profit in the actual trade. Supposing such a result possible to the exporter, it is clear that he makes his profit entirely out of his neighbor the importer, who has to buy his bill, and consequently to pay the premium. Both cannot be right in their views, and in point of fact both are wrong until they begin to realize that the inconvertible paper dollar, rouble, or florin is not so valuable and has not the same purchasing power as the metallic money, or as the paper notes maintained in a constant practical convertibility. This fact is demonstrated within the country itself by the more or less gradual and uniform, but inevitable, rise of prices of all commodities, and of bullion among others, in this new currency. It is discovered very early in the foreign exchanges, not only since there is likely to be an excess of imports over exports when a country is in the act of denuding itself of specie, but because the foreigner has to be careful to get the value of his goods or produce as it is known to him in his own money; and any important change in the money of a country, therefore, obtains a sharp valuation abroad. Both at home and abroad it is soon discovered that the par of exchange, as formerly established, has passed away, and that a new par has come into operation under the pure force of the natural relations of the case. The importer finds no advantage from the advancing prices of what he imports in the domestic markets, since he has to pay more of the domestic money for the foreign bill of exchange by which he discharges the debt for his imports; and the exporter finds no advantage in the premium on his foreign bill which he sells to the importer, since it only replaces what he has already paid in the increased cost of his commodities and other outlays.

This action of exchange is now so familiar as to require little illustration; but a commonplace example may be given, to render more obvious the result on both sides. A, a merchant in London, at a period when the rate of exchange between London and Hamburg is at exact par, can sell a hogshead of sugar worth £50 in London to B in Hamburg for £100, or weight for weight in gold of 100 sovereigns. He exports, draws his bill on B, which he sells for £100, and derives his profit of £50 on the sugar, less expenses of transit. At another period of equal scarcity and dearness of sugar in Hamburg as compared with London, but when the currency of England has been under suspension of specie payment, and has been so much increased in quantity that prices of sugar and other commodities have doubled in the mean while, the hogshead of sugar now sells in London for £100. A, however, again exports, draws on B for £100, and the rate of exchange being now 100 per cent. in favor of Hamburg against the currency of England, sells the bill for £200 in London, and makes a profit in the English currency of £100, equal to £50 in undepreciated money—the same profit as he made before. The results to B, all things being equal as supposed save the depreciation of the English currency, are also the same in both transactions. The case of a British importer, in corresponding circumstances, would not differ from that of A, the exporter; because, however unfavorable the *nominal* exchange might be in the bills by which he paid for his imports from abroad, he would be repaid by the increased nominal prices obtained for them in the home market.

As long as a change in the par of the money of two countries is not recognized or clearly understood, there may be much miscalculation and irregular profit and loss among the merchants on both sides. On the other hand, as soon as noted and brought under generally acknowledged estimate, it does not interfere, *per se*, with the movement of produce or the fair profits of those engaged in foreign trade.

But how is the depreciation of an inconvertible paper currency to be measured? As a convertible paper currency only maintains its par with gold by being always payable on demand in the gold it promises to pay, so an inconvertible paper currency falls just so much below the par of gold as the difference between the amount of gold it professes to be and the amount of gold it exchanges for in its own market. The price of bullion in an inconvertible paper currency rises like that of other commodities—not, indeed, in its general market value, but in its market price within the sphere of the currency; and the amount of this rise marks what may be called either a discount on the paper money or a premium on the gold, and this discount or premium becomes a measure of the depreciation of the currency. It is by no means a satisfactory standard, for it may vary from day to day, and in this respect be as unlike as possible to a par of exchange between the gold and silver moneys alike of small and great states, which may hold good without variation for any number of years. There may also be restrictions on the sale of bullion, prohibition of the export of bullion, and speculative combinations of paper-holders and gold-holders to "corner" each other, and the fluctuations may be not only constant but sometimes extreme. But, with all its disadvantages, the relation of gold to the paper money, as it happens to be revealed in the markets, is the only measure of the depreciation to be had, and the premium on gold has consequently to be reckoned as a necessary component part of the rate of exchange with other countries.

The history of the last twenty years, though years of abundant production of gold and silver and great material prosperity, has been marked by an extended resort to inconvertible paper money in many parts of the world; and the exchanges of Russia, Austria, Italy, and many other countries might be referred to for ample proofs of the effect of this monetary expedient on the nominal par, and the extraordinary fluctuations to which it gives rise. The "greenback" money of the United States, a result of the war between North and South, is probably the most familiar, while in some respects also the most instructive example. The par of the American dollar to the pound sterling was originally struck in the rough proportion of $40 equal to £9, which made the quotation at New York $4.44 to the pound. or, as stated on the British side, 54d. to the dollar. But on strict inquiry this did not correspond with the gold, weight for weight, in the dollar and the sovereign, and was in fact 9 per cent. too favorable to the dollar. It thus appeared that to correct the scales $9 had to be thrown in with every hundred, and adhering to the old par with the tenacity which has been the general commercial practice in such cases, the exchanges were held to be in equilibrium when bills on London stood at $109 for every hundred of the purchase-money, or 9 per cent. nominal premium in favor of England. The par, as more definitely stated, was then in New York $4.85 equal to the pound, or in London 49½d. equal to the dollar, and this remained the mean specie point from which all other influences acting on the exchange caused the rate either to rise or to fall, until the period of the civil war, and the issue of paper money, guaranteed by Federal security, but inconvertible. The effect of the new currency on the exchanges was neither immediate nor suddenly great in its proportions. The wide territory and large population of the Northern States were a powerful absorbent. Moreover, as the Government increased its issues the banks withdrew their notes, which had the effect *pro tanto* of staying the progress of depreciation. But gold was still absolutely necessary in the ports, and a premium on gold, inevitable from the first, increased month by month with the increased issue and circulation of "greenbacks." What the nominal par of exchange now was became a sort of arithmetical puzzle; for, taking the exchange of New York on London alone, without respect to other countries trading with the United States (the money of some of which was undergoing similar depreciation at the same period), the established premium of 9 per cent. in favor of London was met and supplemented by this new premium on gold, and to add the one premium to the other would not be enough, because the dollar itself was now fallen away from its value when the $9 to the hundred had been strictly ascertained and arranged as a corrective of the original rough par of $40 equal to £9. The Government, issuing the new currency that produced this disturbance in the foreign exchanges, had no theory on the subject, and only made some feeble attempts to regulate the sale of bullion. The adjustment was left in the main to the calculation of bankers and merchants on both sides, in presence of the natural causes in operation, and the solution thus attained may be all the more significant. The premium on gold in its exchange at New York with the paper currency was added to the former premium of 9 per cent. in favor of London, and the 9 per cent. itself, marked of old in $9 of bullion value, was increased *pro rata* by the same premium.[1] This rule has since regulated the nominal par of exchange between New York and London through wide ranges of fluctuation. The exchange was often as high as 180 during the war, so that the quotation must often have been—New York $8·0 = £1, London 30d. = $1·0. It is no less worthy of remark that, without the actual resumption of specie payment, the "greenback" dollar has been quoted of late in New York and other American cities at the metallic par of 4·85—a rare though not unprecedented phenomenon, to be attributed to a severe financial and commercial crisis, followed by four years of lowered prices, steady excess of exports over imports, and accumulation of bullion.

The effect of issues of inconvertible paper money, or the suspension of cash payment of paper currency already in circulation on the par of exchange, is the same as that of a change of the standard of value, a debasement of the coinage, or, where in one of two countries the money is gold, and in the other silver, a depreciation of one metal as compared with the other. When two countries par their gold coins, the object is to arrive at a common term by which value for value will be paid, in equivalent weight and purity of metal, out of the money of each other. When one of them displaces its gold coins by inconvertible paper money, the same object has to be attained, and this is reached, though not so fixedly as in the par of metallic coins, by the premium which gold commands over the paper money in the sphere of its currency. The former par in such cases may be adhered to as a landmark, and this gold premium may be treated as nominal premium on one side and nominal discount on the other, but it is substantially of the nature of par of exchange, and becomes a necessary integer of the rate of exchange. In the case of countries of one of which gold, and of the other silver, is the standard money, the nominal par is subject to variation from changes in the relative market value of the two metals. If, for example, the relation on which the par proceeded was 15 ounces of silver equal to 1 ounce of gold, and the depreciation of silver becomes such that 17 ounces will buy only 1 ounce of gold, the par of exchange between the two countries will follow the course of that depreciation.

The course of the exchanges of India has been much affected of late years by the depreciation of silver, and so also those of all silver-paying countries. The drawer of a bill sterling on London in Calcutta or Bombay is literally selling gold for silver, and whatever the more ordinary par may have been, is bound to take into account the market value of silver. In 1876, owing to the large quantity of demonetized German silver thrown upon the market, less directly to a pre-existing cause, namely, the large extent to which silver had been cast out even of the fractional currency of countries largely committed to inconvertible paper, and also to exaggerated reports of abundant increase of production in the American mines, silver fell to 47d. an ounce—about the lowest point reached in its relation to gold, and a great reduction from what had long been its par value of 5s. 2d. an ounce. The consequence was that the Indian rate of exchange declined to 1s. 6½d. per rupee in six months' sight bills on London, or, in other words, that the rupee, having an accustomed par value of near 2s., was worth only 1s. 6½d. sterling, *minus* say seven months' interest accruing between the date and the maturity of the bill. It is difficult, or rather impossible, as foreign bills are negotiated, to distinguish the respective force of the various causes operating on the rate of exchange. In the case of India nearly all the constituents of exchange are adverse to the value of the rupee, save that of rate of interest, which is higher in Calcutta or Bombay than in London. The Indian drawer of a six months' bill on London would lose more by holding the bill till its maturity than the buyer of the bill who remits it to London for acceptance and discount; and some middle term must be struck between them, according as the rates of interest in India and England vary. But, on the other hand, India is a country where the imports always exceed the exports, where foreign capital in many forms has been largely invested and has to render its annual tribute, and where the financial relations of the Government of India and the Government of England are such that the latter has to draw periodically a considerable amount of bills on the Indian treasuries; so that, whatever the par of gold and silver might be, the supply of bills on London would always be less than the demand, or, in other words, the Indian creditors have some advantage over the Indian debtors of London in the rate of exchange. Were gold the money of India, the range of the premium thus established on the bill on London would be limited by the cost of remitting gold; but silver being the money of India, the action of the premium itself, or rather of the relative indebtedness of which it is the result, is to extend the range of the specie limit by lessening the demand for silver abroad. The rupee being less valuable than it formerly was, does less work in the Indian circulation and is all the more needed at home; to export it in payment of the adverse balance of trade would be to send it where it is less valuable still. It may thus be concluded that the depreciation of silver has been much the most potent and constant element in the adverse current of Indian exchange. The price of silver having since 1876 risen to 53½d., the rate of six months' bills in London has risen to 1s. 8⅜d. The rate of Indian exchange rises in the export seasons when the supply of foreign bills is increased; and it rises with the price of silver at all seasons.

---

[1] Mr. Goschen, in his book on *Foreign Exchanges*, gives the following definition of the process of exchange between New York and London:—"If, before the issue of paper money, the purchaser of a bill on England paid 100 dollars and 9 dollars for it, he would, if the premium on gold had risen to 50 per ct., in the first place pay 150 dollars instead of the 100, and in the second 13½ dollars instead of 9 dollars, or half as much again as what we may call the correcting premium. Thus, if the price of bills when gold stood at 150 was 163½, this price would correspond to the price of 109 at the time when there was no premium on gold. The price might rise to 165, or fall to 161, according as there was supply or demand, but the mean point would be ascertained by the process which has been described."

In the silver exchange between Hamburg and London the same rule prevailed. In Hamburg silver was money, but in England and other countries which have a gold standard it is only merchandise, and a rise or fall in the price of silver affected the value of a bill on Hamburg or a bill drawn on Hamburg in English sovereigns. Where a double standard exists, as in France, bills between that country and another are drawn in the standard which is common to both. Thus in the direct exchange between Paris and London, the bills are usually or almost wholly gold bills.

Supply and demand of bills.

2. Were there a common international money, the supply and demand of bills would be the chief determining cause of a rise or fall in the rate of exchange. Hence, in distinction from the nominal par, the relation of supply and demand of bills has been called "real exchange." Mr. Goschen speaks of it as "the primary element in the value of bills," which, from so practical an authority, may be regarded as indicating that, notwithstanding all the varieties of money, this continues to hold the chief place in the negotiation of bills of exchange, or that, the nominal par being once determined, or a common principle formed for its rectification when the money of a country has depreciated, it ceases to require the calculation which must always be given to the supply and demand of bills in the market. As the sum of the bills offered, and the sum ready to be bought, never express the whole of the claims upon, or the whole of the debts due to a country, but only such claims as have been drawn for, and debts the time of payment of which has come or is nearly approaching, there is always more or less change of the relation of supply and demand, as well as opportunity of judgment as to the probable course of the market, and means of applying correctives if the balance be swaying too much on the one side or the other. If the price of foreign bills be depressed for want of buyers, drawers may hold back a little; on the other hand, if the demand has raised the price of bills, all who have sums to draw for will be induced to take advantage of the market, and so increase the supply. The buyers are moved in the same way, quickening or delaying their purchase within the limits of their period of remittance, according to their judgment of the probable course of the exchange. But the buyer cannot delay beyond the day when his remittance is due in the foreign country, nor the drawer beyond the ultimate date of drawing, or his own need of realizing the value of his bill; so that, amidst this oscillation, it is always the peremptory business to be done that determines the effect of supply and demand on the rate of exchange. The debtors of a foreign country, finding the supply of bills on that country less than the demand, will be ready to give an addition of price for them, in proportion to the scarcity, within the cost or up to the cost of remitting specie; and the creditors or drawers on a foreign country will submit in the other extremity to discount on their bills within the cost of sending them to their correspondent or banker's correspondent abroad, with orders to take payment and remit the proceeds in specie. When the course of exchange, as thus pursued from week to week, reveals that the claims immediate and maturing upon any country are greater than the debts due to it, and cannot be discharged through the mechanism of direct and indirect bills of exchange, its balance of debt can only be paid by remittances of bullion or an increased export of goods and produce, or other exportable value.

It is unnecessary to dwell further on the law of supply and demand of bills, which differs little from that of other commodities, beyond remarking that an inadequate idea would be formed of the efficacy of bills of exchange in liquidating international debts without taking into account an immense banking organization, aided by bill-brokers and dealers in foreign exchange, who have all the main currents of indebtedness under their eyes, and know with the precison of practice how the debts of one centre can be met by its claims upon others, and a stupendous mass of conflicting operations, ordinary and extraordinary, be most economically effected. Fifty or a hundred millions sterling, as in the case of the French indemnity to Germany, can be transferred from Paris to Berlin at a time without material disturbance of the more ordinary business of exchange. The British chancellor of the exchequer could transfer three millions and a quarter from London to Washington in payment of the Alabama indemnity before the operation was well known in the principal marts of the two countries. When England is lending ten millions to India, fifteen millions to the Australian colonies, or twenty millions to innumerable enterprises in the United States and Canada, or so many millions to Russia, Turkey, or the River Plate republics—or making several of such loans at nearly about the same time, as has sometimes happened—the effect on the foreign exchanges, though considerable, is seldom thought of. A foreign loan is usually taken out—a large part in goods, another part in bills, and the balance most probably in specie. But the effect of a foreign loan on the exchanges is exactly the same as if the borrowing country had exported produce to the lending country equivalent to the amount of the loan, placing it in debt to that amount. The lender has become bound by contract to pay so much to the borrower. The whole weight of a foreign loan, therefore, falls at once to what may be called the adverse exchange of the lending country or the favorable or less unfavorable exchange of the borrowing country. The reverse action comes in half-yearly or yearly rills, when the interest and redemptions of the loan, spread over a series of years, are payable. A foreign loan, if prudently and honorably conceived, may thus, as regards even the rate of exchange, be advantageous on both sides. The lending country gives a great advantage at once to the borrowing country in its exchange, which may be no evil in itself, and which the borrowing country, if the terms of the loan be fulfilled, repays in a period of years, during which its exporting and paying power may be reasonably expected to increase, which may be a common good. It may be added that foreign loans and investments of capital in foreign countries, badly as many may have been conducted, yet in their product of sound and marketable stocks and shares come to play a generally useful part in the rates of exchange. The value of commercial bills might not be so equable between such centres as London and Paris, or London and New York, without the intervention of stock-exchange securities.

Rate of interest.

3. It is obvious that the number of days or months a bill has to run before payable imports the question of interest as an element of valuation in the rate of exchange. The usance of foreign bills is extremely various, from short to long, from payable at sight to payable at six months after sight; and days of grace are allowed by the law or custom of some few countries considerable enough to be taken into count. Where a bill is payable so many days or months after sight the time that must elapse, in the ordinary course of communication, before it can be presented for acceptance, is a further prolongation of the currency of the bill. The buyer takes it with this weight of time upon it, and, whatever the period may be, is entitled to a concession equivalent to the interest of the money which he pays, the converse happening in the case

of stocks and shares on which dividend or interest has accrued at the period of sale, and must be accounted for to the seller in the price. But the important question in foreign bills of exchange is what rate of interest is to rule in the transaction. Is it that of the country where the bill is drawn, or the country where it is payable, or a compromise between the two? The drawer, in offering to transfer his bill to a buyer, is wholly in the domain of the rate of interest in his own market. If he sells, he gets the value of the bill in money worth so much interest; and if he holds the bill till its maturity, or to some period nearer its maturity, he deprives himself of money for that period worth the same interest. The buyer who, in the event of an exchange, pays down the value of the bill in money would seem to be under the same condition; but in reality, when closely examined, the relations of the buyer and the seller of a bill of exchange to the rate of interest are different. The buyer has a debt to pay in the country on which the bill is drawn, which debt he is bound to pay *now;* and for his purpose the bill is all the more valuable the less weight of interest it bears, or, in other words, the less discount it is subject to. Supposing, therefore, the bill is drawn in a country where the rate of interest is 7 per cent. on a country where the rate of interest is 3½ per cent., possession of the bill will be more profitable, as regards rate of interest, to the buyer than to the seller. If the seller holds the bill, it bears 100 per cent. more weight of interest than it would bear in the hands of the buyer. If the rates of interest in the two countries be exactly reversed, the bill bears 100 per cent. more of this weight in the hands of the buyer, than of the seller. Thus, after the par of the currencies has been established, which, as we have seen, is always practically established, even in the case of an inconvertible paper currency, by the bullion test, and must be regarded as the first condition of all foreign exchange, this question of interest is sufficiently important to modify the action of supply and demand, and of other circumstances operating either to raise the rate of exchange above or depress it below the par of the currencies. It is one of those innumerable commercial relations in which there is an advantage to buyer or seller, but which cannot be realized without mutuality, and which consequently helps them to a transaction. If the advantage of rate of interest be in favor of the buyer of a bill of exchange he will be inclined, other elements of valuation considered, to give a somewhat larger price for it than if this were not in the account; and if the advantage be in favor of the seller he will be less exacting. The whole advantage on either side may not be realized in the actual terms in either case; but it will have had some effect towards a mediation of the prices.

The price of a bill, apart from other elements, is the sum of the bill *minus* the interest it bears at the rate of discount in the country where it is payable. Yet in the practical negotiation this does not hold exact because the value of the bill to the seller or the buyer is always modified by the relation of the rate of interest where it is payable to the rate of interest where it is drawn.

Rate of interest, though in the aspect it presents to the seller and buyer of a bill thus plain enough, yet comes to play so great a part in the general course of exchange that it is worth while to pursue the subject a little further. Rate of interest regulates the supply and demand of bills, and effects the rate of exchange through that element; where the balance of indebtedness is against a country an advance of the rate of interest tends to restrain imports and to stimulate exports, by which effects the balance of debt is reduced; and where the action of trade is not sufficient to overcome the evil, further rises of the rate of interest may be employed to attract imports of foreign capital and specie. In the case we have supposed of two countries, where the rate of interest is 100 per cent. more in the one than the other, this relation of their rates of interest may be the normal relation from the greater abundance or the greater profits of capital in the one than the other, and their exchange may be supposed to be in equilibrium, so that this normal relation is not disturbed by any changes of rate of interest to correct the supply and demand of bills, or the balance of trade. The effect, as we have seen, of difference of interest was in favor of the price of the bill drawn by the country of high interest on the country of low interest, from the fact that the buyer was moving the bill out of a market where it bore a weight of 7 per cent. to one where it bore a weight of only 3½ per cent. interest. But suppose the balance of indebtedness has become so adverse to the country of low interest that the rate has been increased to 7 per cent. in order to improve the course of exchange, and that the effect has been, as must more or less follow, to render the foreign drawer less eager to sell, and the foreign remitter more eager to buy. The remitter or buyer will find the new influence thus introduced operating in the same direction—viz., in favor of the price of the bill; but, on the other hand, the difference of interest has disappeared. Two effects have thus proceeded from the same cause, which neutralize each other so far as they go; and the remitter, instead of buying a bill, may as well, as regards the rate of interest in the two countries, be drawn upon by his foreign creditor. If the rate of interest be further increased to 10 per cent., the drawer may be induced to hold the bill in order to save the 3 per cent. of discount above the rate of interest in his own market, or an investing buyer may intervene, and give such a price for the bill as will allow the seller 1½ or 1 per cent. of the profit, and leave 1½ or 2 per cent. to himself. In either case the bill would be held till it matured, and relief to that extent be afforded to the exchange of the country raising its rate of interest. But it is clear that not until the rate were raised 3, 4, or 5 per cent. above the rates of the countries drawing upon it could any effect of this kind be produced. It thus appears that the function of rate of interest in controlling the supply and demand of bills is a strictly limited function; and this limitation will probably be found in all the effects expected from it on the state of exchange. It may hasten the course of payments due to a country, but it does not lessen the adverse balance of indebtedness, nor can it much retard the pressure of the foreign claims. It may restrain importation of foreign goods, but it may not at the same time increase exportation of domestic goods; or, if increasing export, it may not diminish import. These are results which will depend on many other causes. It may tend to lower prices, and thus seem to check import, while facilitating export; but, forming in itself an addition to the cost of production and exchange, it may render much outward as well as inward trade less possible. If the rate of interest be carried high enough it may attract much capital from neighboring countries. Foreign bankers and lenders will buy up bills on the country as the best mode of importing their capital, or may import specie; and admirable as this service may often be, yet it does not lessen the foreign indebtedness of the country. It only transmutes one form of the adverse balance into another more convenient for the time being; and in the mean while, if the high rate of interest has crippled the productive and exporting resources of the country, little good or a reverse balance of evil may have been done. Hence bullion reserves are either inadequate in the plan of their formation, or they miss their use and efficacy if, when a heavy balance of indebtedness appears in the exchanges, they cannot be trenched upon without large and excited advances of the rate of interest.

Cost of specie remittance.

4. Nothing is more definite in the system of exchange than what has been more than once stated in the course of these remarks, namely, that the cost of remitting specie forms the limit of variation in the rates of bills. That the buyer of a foreign bill will not give more for it than the cost of remitting specie equal in amount to his foreign debt is an axiom which holds good under all the ordinary conditions. But there are exceptions to the rule where the conditions vary from the ordinary. From the countries of productive gold and silver mines bullion flows abroad as naturally as the corn, cotton, wine, or oil which forms the special merchandise of a country, and it will so flow irrespective of supply and demand of bills, rate of interest, and other causes which have so much sway in rates of exchange. San Francisco will export gold and silver to London in all states of supply and demand of bills, and when its rate of interest may be double that of the Bank of England, and in the common parlance money is there dearer than in London, though it may be only that the average profits of capital are larger in the one place than in the other. If bullion is needed at New York, and commanding a higher premium on the Federal currency, it will be matter of calculation to the bullion exporter at San Francisco whether to send a consignment to New York or to London. If, since the discovery of the Californian mines, a metallic currency had been established throughout the Federal Union, the United

States would no doubt have absorbed a proportion of the gold and silver shipped to Europe; but this object accomplished, the export to Europe would have proceeded much as it has been proceeding. In short, from gold and silver producing countries the export of bullion is not a remittance of money, but a transmission of the exportable produce of labor, which but for export would not have been produced. Then, there is the case of exchange between countries of silver standard and countries of gold standard, from either of which remittances of specie cannot be made without exact reference to the market value of the two metals. This will have been already marked in the par of exchange between the gold and the silver country, but it will have introduced a new element into the cost of remittance, since the specie remitted will have to be sold into the specie standard of the country to which it is remitted. Silver from India and China, for example, in the circumstances of recent years, cannot be remitted in payment of an adverse balance of exchange without taking into account a subsequent act of merchandise—namely, what the silver will bring in the gold of England; and this, with silver under a course of depreciation, may be so doubtful that the buyer of a bill on London will rather yield in the rate of exchange, and give some fraction more of a rupee for the pound sterling than run the risk of it. Neither in payment of an adverse balance of debt, nor in transferring capital from one country to another with the view of taking advantage of a higher rate of interest, can specie be remitted between gold and silver standard countries free from this contingency. A Hamburg capitalist wishes to profit by a rate of interest two or three per cent. higher in England than at home. He will therefore buy bills on London up to a certain limit of price; if he has any gold, he will then remit gold rather than exceed this limit for bills; or he will remit the silver specie of Hamburg subject to its market value in London. In this case, indeed, the foreign capitalist has more than one act of merchandise to contemplate, for he has to look to the reverse action when the rate of interest may be higher at home than in England, and when it will be his motive to re-convert his English sovereigns into silver, which in the relative condition of the market value of the two metals may be either favorable or unfavorable. If unfavorable, he will buy bills of England on Hamburg, or some other centre with which the exchange is favorable to Hamburg, rather than re-transmit silver at a higher cost than the rate of the bills. It is obvious that all this does not alter the principle that the cost of specie remittance is the limit of rate of exchange on bills, but only that it gives a larger range to the variation of rate, and to the specie limit, between two countries whose money and standard of value are of different metals than would exist between two countries where they were of the same metal.

In exchange between a gold-paying and a silver-paying country, one of which, say the silver country, has gone largely into an inconvertible paper currency, the case becomes more complicated, and the specie limit to adverse rate on bills recedes, till, if the inconvertibility be so great as to be incapable of valuation, or the Government in its ignorance or alarm has prohibited the export of specie, the limit is wholly lost. A Russian merchant, who has ample silver and paper roubles at command for his purposes, but has a debt to discharge in America, or needs to lift a cargo of cotton at Liverpool or of sugar at Glasgow, and finds that the remittance even of such specie as he may be able to produce is illegal, must buy a foreign bill or a banker's draft on London at any price. At this stage the rate of exchange passes out of the domain of principle, or natural action of principle, into that of purely arbitrary considerations. When, from much less sufficient causes, general discredit passes upon a country, the rate at which its bills or acceptances may be valued is scarcely more reducible to rule. It might even be difficult to define why in the same general circumstances there should be collaterally a higher and lower course of exchange, and the bills drawn or payable by one firm should differ in their rate from those drawn or payable by another firm. It is only by removing abnormal conditions that one arrives at the underlying principle which governs exchange, and determines the success with which it is conducted.

Accordingly it is in countries where bullion, separated from its necessary export from the mines, has become money, and forms the common standard of value in their international trade, that the limitation of the rate of exchange by the cost of specie remittance is most clearly visible. Between all nations trading on a gold basis there is a well-known and definite point above and below the par of exchange where it becomes profitable to move gold from one to the other, and which marks the extreme range of variation in the price of bills. Thus in the exchange of London with Paris, New York, and Berlin respectively, 25·10, 4·81, and 20·30 mark a point in the price of bills below par when it pays to send gold from London to these centres; and, on the other hand, 25·30, 4·87, 20·50, a point above par when it becomes profitable to move gold from Paris, New York, or Berlin to London.

When the rate of exchange, touching, under the supply and demand of bills and other elements of valuation, these extreme points on one side or the other, and tending to exceed them, is the result of an actual over-indebtedness, a transmission of bullion is the best and most satisfactory mode of settlement. It directly reduces the balance of debt, and renders the price of bills again more equitable to the traders. All other modes of fencing it off, save an increased export of goods and produce, are more or less illusory. If, in such a juncture, an amount of foreign capital has been invested in bills on the country with the view of holding them to maturity for sake of profit in rate of interest, and now with the view of realizing the value of the bills in gold they should be pressed on the market before maturity for discount, an advance of one per cent. in the rate of discount may be sufficient to induce the foreign capitalists to hold the bills till they mature. And another advance of one per cent. in the rate of discount may induce them to reinvest in other bills on the country. But the root of the adverse exchange will not have been removed. It will always appear when the foreign capital thus invested in bills on the country is from any cause withdrawn, and until the over-indebtedness is liquidated by remittances of specie, increased export of produce, or transfers of salable shares and securities.

If, on the other hand, the rate of exchange has been brought to the specie limit by bills, representing no actual debt, but drawn and accepted solely for the purpose of moving bullion, as may probably happen, there is no remedy for what may prove an inordinate demand for specie by irregular means but the detection of the bills, and either refusing them discount or discounting them under exceptionally high rates of interest.

Correct judgment, or its opposite, panic.

5. An exposition, however brief, of the causes operating on the rate of exchange would scarce be complete without including the effect of opinion or estimate, correct or erroneous, of the probable course of the market; and therefore it may be observed that a judgment has to be formed in every new phase of the numerous fluctuations. The seller of bills finds that within a few days the market has taken an unfavorable turn. If he judges that this has arisen from merely accidental or temporary causes he will be inclined to hold his bills for what he deems their true value; or if, on the contrary, he judges that the causes operating are more deeply seated, and likely to become stronger for a time, he will sell with the least possible delay. Should his judgment be justified by the event he will have done what is right for him, if otherwise he will have done what is wrong; but in either case, his abstention or action will have affected the supply and demand of bills in the mean while. In all the great marts of exchange, and in London probably more than in others, there are frequent wave-currents so to speak, which cannot be rightly interpreted either as the sign of a protracted state of exchange between the points of the compass in which they flow, or of the general foreign indebtedness of the centre upon which they are directed. When New York balances its debts to China and India by bills on London, the bills affect the course of Eastern exchange; but they lose much of the significance they might otherwise bear when it is considered that New York is in course of compensating London in other directions. These operations come to be understood and systematized by dealers and agents in bills with much accuracy; but in addition to the judgment that may be formed by a thorough analysis of the substance of the various currents of exchange, there is the effect of opinion on external events, which, though of almost daily occurrence in one quarter or another, are wholly of future account, and which impress, not only the connoisseurs of

exchange, but the whole body of drawers and remitters, from whom the original impulse on the action of exchange in all cases comes. The examples that might be adduced of the great effect of passing events on exchange are innumerable. In the beginning of 1861, when the disastrous rupture between North and South had occurred, and war was imminent, the United States had a most favorable balance of trade with England and Europe. Their exports of wheat and flour and cotton in the previous year had at once reached a maximum in quantity and a rise in value. The drawer of a bill on London was in so good a position that he had only to wait for the buyer to get the value of his bill up to the specie point. But so eager were the drawers, in view of the pending outbreak of civil war, to realize what was owing to them abroad, that they threw their bills on the market in an abundance which reduced their price to the other end of the scale. This, of course, had its converse effect at London, and bills on New York were there selling at such a premium that it seemed as if the United States would have to remit bullion to Europe. The volume of bills, however, told its own tale after a while. England had to remit bullion in large quantity to the United States, and then people began to awake to the perception that, in the exchange transactions, the one element most important of all had been left out—namely, the relative indebtedness. It must have been a time of much profit to those on both sides of the Atlantic who knew the actual state of affairs, and of much loss to those who did not know, of whom there can be little doubt that the latter were much the greater number, but the balance of value between the two countries, as expressed on the face of the bills, had to be rendered all the same.

To take a more recent case. The exchange value of the Russian rouble during the last twelve months of war between Russia and Turkey will amply illustrate what is meant by the prevailing judgment on events in their future aspect, which, while proceeding on a certain amount of reason, yet borders on panic, and may be of the nature of panic. The issue of paper roubles had gone the length of 730 millions before the war, and there was a constantly increased remission during the year, counteracted in some measure by conversions into loans bearing interest. On the mobilization of the troops the value of the rouble was 29d. to 30d.; on war being declared it fell to 27d.; when it seemed as if Plevna could not be taken it sank to 22½d.; when Plevna fell it rose to 26¾d.; and when it followed that the conquest of Turkey and an armistice did not end the difficulties, it fell to the lowest point it had touched, 22⅛d.

Favorable and unfavorable exchange.

The term "favorable exchange," as commonly used, not only means a state of the exchanges when the debts due to a country abroad are so much greater than what it owes abroad as to affect potentially the demand and supply of bills, and when the money of the country so situated, as expressed in the price of bills, is equal to more of the money of a foreign country than the nominal par—when its bills on abroad, in short, are dull of sale, while the foreign bills on itself are in much demand; it is also applied to all stages, moderate or extreme, of this relation of the foreign exchanges. And so the term "unfavorable," of course, applies to the opposite conditions. If these phrases had ever any reference to the prosperity of the foreign trade of a country, they must have arisen under the sway of "the mercantile system" of the last century, the principle of which was that a balance payable in specie is the cardinal condition of prosperous trade with any foreign country; or, if introduced under that erroneous theory, they have been prolonged by the usage of bankers and other dealers in foreign exchange, who, having large liabilities entailing bullion payment, naturally consider a state of exchange which is on the eve of bringing specie more favorable than one on the eve of taking it away. This is quite true in the monetary view of the question, and it is true also as to the relative indebtedness for the time being. But it is not true to extremes even in a monetary sense. The condition of a country to which specie was always flowing in and never going out would be a realization of the fate of Midas. The most favorable exchange, therefore, is that where there are only moderate oscillations up or down from the par of exchange.

While the terms "favorable" and "unfavorable" are thus somewhat misleading as regards substantial interests, they are involved in a minor technical complexity, which, though well understood by those in the business, may here be stated. The terms would be strictly applicable in the sense they are used, were the rate of exchange always quoted in the home money. The *certain* properly in exchange transactions is the number of pounds, dollars, francs, or florins a remitter has to pay abroad; the *uncertain* is what amount of his own money is equal to this amount of the foreign money. Were the quotation on both sides respectively always made in the home money, the fall or rise of the quotation would always be identifiable with such terms as "favorable" or "unfavorable." Both drawers and remitters would be so familiar with their significance as to know what they meant. But this is not the practice, and, with so much variety of currency, could hardly have been the developed practice, of exchange. The pound sterling of England is the largest monetary unit, and there is always facility of expressing minute shades of difference in the smaller units, more especially when, as in the case of Paris or New York, they have a decimal character. In London, consequently, the public only hear quotations of rate of exchange with such countries as France and the United States in the foreign money—London thus giving what is called the *certain*, and the smaller moneys the *variable*. On the other hand, not only in the Australian and other British colonies, where the standard of value is the same as in the parent country, but in such large commercial regions as China and India the quotation of rate of exchange on both sides is always expressed in sterling. The Chinese tael of silver is worth so many English pence sterling at Canton; and the rupee is worth so many English pence at Bombay or Calcutta; and in the same terms run the quotations in London. The practice may not alter in any iota the true rate of exchange, but it has the result that when the rate is quoted in sterling money, as in the Indian, Chinese, and Australian exchanges, every drop in the quotation is "more favorable" to England, every rise "less favorable," and this will hold good whether the quotations are made in England or in India, China, or Australia; whereas, on the other hand, when exchanges are quoted in foreign money—French, German, or American, etc.—every drop in the rate by the same rule is "less favorable," every rise in the rate "more favorable" to England, whether the quotation be made in England or in the foreign countries.

The states of exchange to which the terms "favorable" and "unfavorable" are thus applied refer wholly to the effect of the demand and supply of bills; so that, since the fluctuations of exchange are due to various causes, it would be an improvement were the quotation always to include the par of exchange, whether between the gold money of one country and the silver money of another, or between either and inconvertible paper, the depreciation of which has to be determined by the gold or silver premium in the country of its currency. The actual rate above or below par would show the effect due to the supply and demand of bills. When a sudden alteration takes place in foreign exchange, nothing is more difficult than to discover the relative force of the cause or causes to which it is to be ascribed, and yet nothing is more necessary to know than this, whether in the correctives that may be applied or in the lessons to be conveyed to importers and exporters.

The limited meaning to be given to such terms as "favorable" and "unfavorable" exchange probably applies to other statements that may arise legitimately in connection with this subject. The principle, for instance, that the profit and loss of exchange transactions fall, not between the two countries concerned, but between the foreign creditors and debtors in one or other, is exact within its own range; but it leaves as an open question whether in a country where from a depreciated and depreciating currency the rate of foreign exchange is always rising, the general result may not be adverse to its interests in export and import trade. In like manner it would be more than questionable, because "the mercantile theory" was wrong in supposing that a balance of foreign trade in specie, or an excess of export value over import value, was the necessary condition of national prosperity, to posit the opposite doctrine that an excess of imports over exports is the only prosperous condition. The solution of this question must depend on what may be called the permanent indebtedness of some countries to others. A country which is under large tribute to foreign capital is assuredly in the right way for itself and for other countries when the value of its exported exceeds that of its imported produce. And so also it may be observed that "rate of interest," if we are correct in our reasoning on that head, may not have the absolute control over the exchanges which was so strongly emphasized for some years after the passing of the Bank Charter Act of 1844, and has since only been modified in practice without any express recognition of the principles involved.

NEGOTIATION OF BILLS OF EXCHANGE.

Rates of exchange have undergone much variation of late years from changes of standard—in some cases from gold to silver, and in others from silver to gold—and from the circulation of forced paper currency. The tendency, however, is to greater uniformity. The gold standard of value adopted at Berlin extends to the whole German empire, and the rates of exchange are now calculated in imperial marks and pfennige at Hamburg, Frankfort-on-the-Maine, Altona, and other German places, where different moneys formerly were used. The money under the new system is 100 pfennige = 1 mark, 20 marks = 1 twenty-mark gold piece (imperial mark) = 19s. 6·954 sterling mint par. The mark, which is the unit or integer of the system, is a silver coin based on the ratio of 1 to 15½ as the relative value of silver and gold. In like manner the kingdom of Italy has extended a uniform exchange; and the rates at Naples, Palermo, Messina, Milan, Turin, Florence, Leghorn, and other Italian towns are similar to the rates at Genoa.

Bills of exchange may be made payable on demand (as the invariable rule is in the case of cheques), at sight, at a certain specified time *after sight* or *after date*, or at *usance*, which means the customary or usual time for which bills are drawn from a given place, and when the time is doubled it is called *double usance*. No bills are now drawn in London at *usance*, and the practice is being gradually dropped in other countries. The usance of bills drawn from France, Holland, and Germany is 30 days' date; from Spain and Portugal, 60 days'; and from Italy, 3 months' date; but the currency of bills is regulated more by the classes of business to which they relate than to the usage of any country. The allowance of *days of grace* is also going out of fashion. *Three days* are still given on bills drawn upon or payable in the United Kingdom otherwise than at sight, and a similar practice holds in the United States. St. Petersburg gives 3 days on sight bills and 10 days on date bills, Copenhagen 8 days, Christiania 8 days; but in these and other cases the allowance may not mark so distinctly the day when a bill is legally due as an interval within which certain legal proceedings of the respective countries cannot be instituted. The practice, which was at one period extremely various, has now been reduced within such narrow limits that in exchange transactions in London no account is taken of days of grace.

Bills of exchange in London are bought and sold through brokers, who go round the mercantile and banking houses, and discover whether they are buyers or sellers of bills. The negotiations are determined on Tuesdays and Fridays, which correspond with the principal post days in foreign exchange business. In London, as in other great commercial cities, bankers deal largely on the rise and fall of exchanges,—buying bills when they expect a rise, and selling bills when they expect a fall.

Foreign bills are generally drawn in duplicate or triplicate, lest the first should miscarry. When thus drawn in sets, the first is payable only "second and third unpaid," the second "first and third unpaid," and the third "first and second unpaid." Where there is a doubt as to the acceptance, the first may be sent unindorsed to a correspondent of the drawer in the place of payment to have it accepted, and the second sold and put in circulation, bearing the name and address of the party holding the first or accepted bill "in case of need," that is, in case he may not have obtained acceptance, and will protect the drawer from having the bill returned through the indorsers. The indorsed second, and the accepted first of exchange, when wafered together, become one bill and are valid.

Exchange, as regards the abundant arithmetic to which it gives rise in its negotiation, may be divided into—(1) Direct, or exchange between two countries wholly based on their rates of exchange, which is so simple as to need no remark; (2) Cross, or exchange between two countries in which a third country has an interest, as when London, say, has 10,000 francs in Paris which he wishes to move to Hamburg, and has to take account of his own course of exchange to Hamburg as well as the direct between Paris and Hamburg, which is only less simple than direct exchange, inasmuch as it requires two formulæ instead of one; and (3) Indirect or arbitrated, where exchange between two countries is conducted through the medium of a third, or more than one other country, and thus becomes more compound as the sphere of the operation is extended. It is an arbitrated rate because it has no actual form, and is found only in figures out of the current rates of exchange between more than two countries. The object being to discover how a debt in one place may be most economically paid from another, the question carries along with it not only the difference between remitting and drawing which exists in the simplest direct exchange—the debtor in the one country and the creditor in the other having always the option of the one remitting or the other drawing—but such *minutiæ* as whether the rate of exchange given be in the foreign money or in sterling, till it results in the following rules:—

> "*For Remittances*:—
>
> "With a foreign rate, any arbitrated rate is better than the direct rate if it is *greater* than the latter;
>
> "With a sterling rate, any arbitrated rate is better than the direct rate if it is *less* than the latter:
>
> "Because in either case, a given sum in sterling will produce a greater sum in foreign money, or a given sum in foreign money will cost a less sum in sterling.
>
> "*For Drafts or Returns*:—
>
> "With a foreign rate, any arbitrated rate is better which is *less* than the direct rate;
>
> "With a sterling rate, any arbitrated rate is better which is *greater* than the direct rate:
>
> "Because, in either case, a greater sum in sterling will be obtained from a given sum drawn for in foreign money."[1]

Nor is this all. Arbitrated rates are calculated for present money; the actual rates of exchange on which they are calculated have been affected by time and rate of interest. In the rate of direct exchange particularly, with which the arbitrated rate has to be compared, this effect has to be estimated, long bills reduced to short, and the difference of interest on them discounted from the basis of calculation *prima facie*. This, in a superficial view, may be counterpoised by drawing speculative bills of long date on a foreign centre, but there are limits to drawing on a place for purposes external to its ordinary course of exchange, and a large amount of bills thus directed without corresponding remittances might produce an effect on the exchanges which would go far to upset the calculation.

It is obvious that arbitration of exchange, thus burdened at every additional length of the chain by difficulties of estimate, cannot be much extended or become too artificial without the risk of miscarriage. But the mediation of direct exchange through a third place is of such common and useful practice that it may be desirable to give an example broad enough to illustrate the general method of equation.

Take London on Paris at 3 months, quoted f.25·55; Paris on London at 3 months, quoted f.25·10.

The discount for 3 months, in the example to be given, is taken at 1 per cent., or 25 cents, which is deducted from the London rate and added to the Paris rate, to make the two short or cash rates; thus reducing the former to f.25·30, and raising the latter to f.25·35.

If this variable price were in sterling, as for instance with Madrid, the allowance for interest would have to be reversed, that is, added to the London price, and subtracted from the price abroad.

EXAMPLE.

From the following rates of bills in London and Paris it is required to find—

1st.—Whether, having money to transmit from London to Paris, it will be better for me to remit direct bills on Paris, or to order bills in Paris to be drawn upon me in London, at the rate of 4 per cent. per annum.

2d.—Whether, having money to draw from Paris, it will be better for my correspondents there to make me remittances, or for me to draw upon them.

3d.—If I have to make remittances to Paris, whether any indirect rate will answer better than the rates of direct bills.

4th.—If I have to obtain returns from Paris, whether any indirect rate will answer better than either of the direct rates.

RATES OF EXCHANGE.

London, June 17.		Paris, June 14.
25·55	Paris at 3 months.	
12″1¼	Amsterdam	209¼
13″10¼	Hamburg	184
121	Frankfort	210⅛
29·47⅛	Leghorn[2]	15 loss = 100 lire for 85 francs.

METHODS OF WORKING THE EQUATIONS.

Amsterdam.

£1?
1 — * 12″1¼ Florins and Stivers.
100 — * 2·09¼ Francs.
Francs 2·09¼ × 12·06¼ = 25·24 Francs.

Hamburg.

£1?
1 — * 13″10¼ Mk. and Sc. = 218¼ Sc.
Sc. 1600 = Mk. 100 — * 184 Francs.
Francs 184 × 218¼ ÷ 1600 = 25·10 Francs.

Frankfort.

£1?
10 — * 121 Florins.
100 — * 210⅛ Francs.
Francs 210⅛ × 121 ÷ 1000 = 25·42 Francs.

---

[1] These rules of arbitrated exchange, accurately given in Tate's *Modern Cambist*, and the verbal puzzle of which turns chiefly on whether the rate forming the basis of calculation be foreign or sterling, lend force to the observation above that the one rate should never be lost in the other one-sidedly. If distinguished in the practical quotation of exchanges, there seems no reason to take other than one in arbitrated exchange.

[2] The loss at Leghorn is owing to cash premium on forced paper currency, but, as it affects London and Paris equally, does not disturb the calculation.

Leghorn.
£1 ?
1 — * 29·47½ Lire Italiane.
100 — * 85 Francs.
Francs 85 × 29·47½ ÷ 100 = 25·06 Francs.

COMPARISON OF THE ARBITRATED RATES.

	Prices.		Pars.
	London.	Paris.	
London, 3 months	25·55	......	25·30 short.
Amsterdam	12″1¼	209¼	25·24
Hamburg	13″10¼	184	25·10
Frankfort	121	210⅛	25·42
Leghorn	29·47½	85	25·06
Paris, 3 months	......	25·10	25·35 short.

FOR DIRECT PAPER.

It appears from the direct rates between London and Paris at 25·30 and 25·35 that—

1st.—To remit or transfer money from London to Paris, it is better for Paris to draw upon London at 25·35 short, than for London to remit to Paris at 25·30 short, because by the former operation there will be made 5 cents. per pound, or about one-fifth per cent., more than by the latter.

2d.—To have returns from Paris, it is better, by the same 5 cents., for London to draw upon Paris than for Paris to remit to London, because the bills will cost so much less French money, or produce so much more in sterling.

FOR INDIRECT PAPER.

1st.—For remittances to Paris, it appears from the arbitrated results that bills on Frankfort, bought in London at 121 florins per £10 sterling, and sold in Paris at 212 francs per 100 florins, will produce 12 cents. more than direct remittances from London to Paris, or 7 cents. more than is yielded by direct drafts of Paris upon London.

2d.—For returns from Paris, it appears from the arbitrated results that bills on Leghorn, bought in Paris at 85 centimes per paper lira Italiana, and sold in London at paper lira Italiana 29·47½ per pound sterling, will cost 29 cents. less than direct bills from Paris, and will give 24 cents. more than drafts from London on Paris.

Such is the manner in which the various exchanges are calculated in order to ascertain which will answer best for a speculation in bills through intermediate places. The contingency of a change of rates has to be considered, and the charges of brokerage and commission on the operation have to be deducted from the result, or may be reduced when the operation is done by branches of the same house, or on joint account.

The elasticity of arbitrated rates of exchange is put to the severest strain when a large subsidy, or monster indemnity, like that of France to Germany, has to be paid by one country to another. In these cases it is necessary to employ extensive banking co-operation, and at centres on which the drafts are heavy to arrange means for the support of the exchange.

PARS OF EXCHANGE.

(Abstracted from Tate's *Modern Cambist*, 16th edition.)

London receives from or gives to

Amsterdam, 11″19 florins and stivers	for	£1 sterling.
Antwerp and Brussels, 25·15 francs	"	£1 sterling.
Hamburg, Berlin, and German bank places, 20″43 imperial marks and pfennige	"	£1 sterling.
Paris, 25·22 francs	"	£1 sterling.
*Vienna,[1] 11·50 florins and kreuz	"	£1 sterling.
*Genoa, and Italian towns, 29·50 lire and centes	"	£1 sterling.
Lisbon, 53¾ pence sterling	"	1 milreis.
Madrid, 48 to 50 pence sterling	"	1 duro (hard dollar).
Gibraltar, 49½ pence sterling	"	1 hard dollar.
Malta, 49 pence sterling	"	1 pezza.
*Constantinople, 125 piastres	"	£1 sterling.
St. Petersburg, 37½ pence sterling	"	1 silver rouble.
Warsaw, 6·40 silver roubles and cop	"	£1 sterling.
Copenhagen, 9·10 rigsdal and sk	"	£1 sterling.
Christiania, 4″66⅓ species and sk	"	£1 sterling.
Stockholm, 18·05 riksdaler	"	£1 sterling.
New York, 49⅓ pence sterling	"	1 gold dollar.
Rio Janeiro, 27 pence sterling	"	1 milreis gold.
Buenos Ayres, 67 shillings sterling	"	1 onca gold.
Calcutta, Bombay, and Rangoon, 23 pence sterling	"	1 Govt. rupee.
Canton,[2] $78\frac{7}{40}$ pence sterling	"	1 tael sycee silver.
Japan, 51 to 52 pence sterling	"	1 Span. or Mex. dollar.

(R. SO.)

EXCHEQUER, COURT OF EXCHEQUER, EXCHEQUER CHAMBER. The name *scaccarium*, from which the word "exchequer" is derived, was used under the Norman kings of England to signify the treasury. Madox, in his learned *History of the Exchequer*, exhausts the possible definitions of the word. According to some, it is connected with *scaccus* or *scaccum*, a chess-board, and the exchequer of England "was in all probability, called scaccarium because a chequered cloth (figured with squares like a chess-board) was anciently wont to be laid on the table in the court or place of that name." "From the Latin," continues Madox, "cometh the French eschequier or exchequier, and the English name from the French. Or if any one thinks more likely that the French word was the ancienter, and the Latin one formed from it, I do not oppose him,—nay, I incline to believe it was so." Another and less probable explanation is, that the original word was statarium, "from its stability, as it was the firm support of the crown or kingdom." But Madox points out that from the early times of the Conquest onwards it was always called scaccarium and never statarium.

At the present day, exchequer means two very different and independent institutions, the historical origin of which is one and the same. It is a court of law—one of the three superior courts at Westminster. It is also the treasury. The connection between the treasury and the court is still kept up in one or two points. The chancellor of the exchequer still takes his seat in the Exchequer Court on certain formal occasions, and the Exchequer Court (or, as it is now called, the Exchequer Division) is still the appropriate tribunal for cases connected with the revenue.

The Exchequer makes its appearance among English institutions in close connection with the King's Court (*curia regis*)—the germ from which so large a portion of the English constitution has sprung. In the language of later times it might be called a committee of that court specially charged with the management of the revenue. The King's Euchequer, says Theodore, "was anciently a member of his court, and was wont to be held in his palace. It was a sort of subaltern court, partly resembling in its model that which was properly called the *curia regis*, for in it the king's barons and great men who used to be in his palace near his royal person ordinarily presided, but sometimes the king himself; in it the king's chief-justiciar, his chancellor, his treasurer, his constable, his marshal, and his chamberlain performed some part of their several offices." And just as the *curia regis* was not a pure court of law, so the Exchequer was not merely a financial council but a court of law. Its principal business, says Madox, related to the revenue, and although the justices on circuit had cognizance of revenue matters, such matters, as they arose, were certified or sent into the Exchequer, "to which place the affairs of the royal revenue tended as to their centre." Madox divides the business of the Exchequer, during the period between the Conquest and the reign of King John, under the head of revenues, causes, non-litigious business, and matters of public policy.

From the reign of Henry III. the Exchequer was recognized as a separate court, the others being the King's Bench and the Common Pleas (*q.v.*). Mr. Stubbs thinks that a separate staff of judges was not assigned to each court until the end of the reign of Henry. The special business of the Exchequer was as before the decision of revenue cases, but from a very early time, and in spite of repeated prohibitions, the lawyers of the Exchequer competed for the ordinary litigious business—the common pleas—of the country. They finally succeeded by means of the well-known fiction which allowed one of the litigants to own that he was indebted to the king, and forbade his opponent to traverse the averment. The organization of the court seems to have been somewhat later in point of time than that of the Common Pleas and the King's Bench. The barons of the Exchequer were not at first recognized as judges. They are not mentioned in the statutes of Nisi Prius (13 Edward I. c. 30, and 14 Edward III. c. 16). In the reign of Elizabeth the Exchequer was definitely recognized a court of co-ordinate jurisdiction with the Common Pleas and the King's Bench.

The Exchequer was further distinguished from the two other courts by possessing an equitable as well as a common law jurisdiction. "The Court of Equity," says Blackstone, "is held before the lord treasurer, the chancellor of the exchequer, the chief baron, and the three *puisne* ones," whereas the common law jurisdiction is exercised by the barons only of the exchequer, and not the treasurer or chancellor. This equity jurisdiction was abolished in 1841, when two additional vice-chancellors were appointed in the Court of Chancery.

---

[1] Those marked (*) include premium on gold or silver on account of depreciation of paper currency. The mint par of Vienna is about 10·35. In Genoa and other Italian cities it would be about 25·30. The full metallic par of the Turkish piastre is 111·5 = £1 sterling. Where the quotations in the above table are sterling with silver money, the price of silver has been taken at 5s. an ounce, and the par of exchange has to be deduced from lower and higher prices of silver, as compared with that standard.

[2] Foreign merchants trading with China usually keep their accounts in dollars and cents; and the dollar issued from the mint at Hong Kong forms an acceptable basis of exchange from that station.

By the Judicature Act of 1873 the Court of Exchequer was abolished as a separate court, and its jurisdiction was transferred to the New High Court of Justice. The Exchequer still survives, however, as one of the divisions of the High Court, and still retains under its new name its old exclusive jurisdiction.

The *Court of Exchequer Chamber* was, until the passing of the Act just referred to, the court of appeal from the three courts of common law. Appeals from any one of these were heard before judges of the other two. It was originally intended (by statute 31 Edward III. c. 12) to determine causes by writs of error from the common law side of the Court of Exchequer, the judges being the lord chancellor, lord treasurer, and the justices of the King's Bench and Common Pleas. A statute of 27 Elizabeth (c. 8) made similar arrangements for writs of error from the King's Bench. The jurisdiction of the Exchequer Chamber is transferred by the Judicature Act to the new Court of Appeal.

The *chancellor of the exchequer* is the second commissioner of the treasury, the first lord being the premier. Occasionally both offices are held by the same person. It is the duty of the chancellor to prepare and lay before the House of Commons the "budget" for the year, and therefore he must be a commoner. The chancellor takes his seat in the Court of Exchequer once a year—at the nomination of persons to serve as sheriffs. (E. R.)

EXCISE, a term of obvious Latin derivation, now well known in public finance, signifying a duty charged on home goods, either in the process of their manufacture or before their sale to the home consumers. This form of taxation implies a commonwealth somewhat advanced in manufactures, markets, and general riches; and it interferes so directly with the industry and liberty of the subject that it has seldom been introduced save in some supreme financial exigency, and has as seldom been borne, even after long usage, with less than the ordinary impatience of taxation. Yet excise duties can boast a respectable antiquity, having a distinct parallel in the *vectigal rerum venalium* (or toll levied on all commodities sold by auction or in public market) of the Romans. But the Roman excise was mild compared with that of modern nations, having never been more than *centesima*, or one per cent., of the value; and it was much shorter-lived than the modern examples, having been first imposed by Augustus, reduced for a time one-half by Tiberius, and finally abolished by Caligula, 38 A.D., so that the Roman excise cannot have had a duration of much more than half a century. Its remission must have been deemed a great boon in the marts of Rome, since it was commemorated by the issue of small brass coins with the legend *Remissis Centesimis*, specimens of which are still to be found in collections.

The history of this branch of revenue in the United Kingdom dates from the period of the civil wars, when the republican Government, following the example of Holland, established, as a means of defraying the heavy expenditure of the time, various duties of excise, which the Royalists when restored to power found too convenient or necessary to be abandoned, notwithstanding their Roundhead origin and general unpopularity. On the contrary, they were destined to be steadily increased both in number and in amount. It is curious that the first commodities selected for excise were those to which this branch of taxation, after great extension, has again in the age of reform and free trade been in a manner permanently reduced, viz., malt liquors, and such kindred beverages as cider, perry, and spruce beer. The other excise duties remaining are chiefly in the form of licenses, such as to kill game and to use and carry guns, to sell gold and silver plate, to pursue the business of appraisers or auctioneers, hawkers or peddlers, pawnbrokers, or patent-medicine vendors, to manufacture tobacco or snuff, to deal in sweets or in foreign wines, to make vinegar, to roast malt, or to use a still in chemistry or otherwise. It may be presumed that the policy of the license duties is not so much to collect revenue, though in the aggregate they yield a large sum, as to guard the main sources of excise, and to place certain classes of dealers, by registration and an annual payment to the exchequer, under a direct legal responsibility. The excise system of the United Kingdom as now pruned and reformed, however, while still the most prolific of all the sources of revenue, is simple in process, and is contentedly borne as compared with what was the case in the last and the beginning of the present century. The wars with Bonaparte strained the Government resources to the uttermost, and excise duties were multiplied and increased in every practicable form. Bricks, candles, calico prints, glass, hides and skins, leather, paper, salt, soap, and other commodities of home manufacture and consumption were placed, with their respective industries, under excise surveillance and fine. When the duties could no longer be increased in number, they were raised in rate. The duty on British spirits, which had begun at a few pence per gallon in 1660, rose step by step to 11s. 8¼d. per gallon in 1820; and the duty on salt was augmented to three or fourfold its value.

The old unpopularity of excise, though now somewhat out of date, must have had real enough grounds. It breaks out in all our literature, from songs and pasquinades to grave political essays and legal commentaries. Blackstone, in quoting the declaration of parliament in 1649 that "excise is the most easy and indifferent levy that can be laid upon the people," adds on his own authority that "from its first original to the present time its very name has been odious to the people of England" (book i. cap. 8, tenth edition, 1786); while the definition of "excise" gravely inserted by Dr. Johnson in the *Dictionary*, at the imminent risk of subjecting the eminent author to a prosecution for libel—viz., "a hateful tax levied upon commodities, and adjudged not by the common judges of property, but wretches hired by those to whom excise is paid"—can hardly be ever forgotten. The levy of excise has more than the disagreeableness of other direct taxation, and though not more inquisitorial than income-tax, establishes an espionage and control over premises and processes of manufacture which are much more offensive as well as sometimes injurious. The caustic feeling of last century points directly enough to much rough and arbitrary administration, which it was possible gradually to correct and mitigate.

But what may be deemed the permanent defect of excise is that it is apt to increase the cost of commodities to consumers far more than the amount of duty levied for the revenue. This has been found on the abolition of excise, whether on bricks, calicoes, leather, paper, or other articles of manufacture. The cheapening effect might not be very immediate or apparent, because the duty when abolished might bear only a very fractional proportion to the natural value of the goods; but under the greater freedom of production have arisen more invention, more skilful and varied appliances, and consequently more economy to consumers, and more expansion of the several industries, than could have been attained under the fiscal restrictions. The inexpediency, even for revenue purposes, of fining and fettering a great number of the most useful and necessary home industries by this kind of impost would seem to be abundantly demonstrated by the fact that the excise revenue of the United Kingdom, while being reduced always within narrower compass, has not suffered eventually in its actual produce to the state. The revenue from excise has never been greater, or much greater, than it is at present. The gross receipts from excise in 1820 were £27,955,810. In the year ended 31st March, 1866, when the larger number of the duties had been abolished, the net revenue from excise was £18,332,868; and in the year ended same date 1877, when excise for some years had been almost wholly confined to British spirits and malt liquors, the net revenue was £27,681,523. The following are the general items of the excise revenue in the latter year:—

Chicory	£2,942
Licenses	3,548,557
Malt	8,040,378
Railways	728,718
Spirits, home made	14,873,165
Sugar, used in brewing	487,763
Total	£27,681,523

So large a revenue from so few sources indicates high duties, and the excise on spirits in particular has been maintained during many years at a rate that would have astonished the people of last century, and yet without any of the evils incident to heavy fiscal exaction. There is a check, which has been often exemplified, to the increase of the rate of excise in the encouragement it gives to illicit manufacture, and the consequent defeat of its object, viz., increase of revenue. The high rates of 11s. 8¼d. per gallon in England, 6s. 2d. in Scotland, and 5s. 7d. in Ireland, to which the excise on home-made spirits was increased at the close of the great wars, gave rise to so much evasion that "more than one-half of the spirits actually consumed in Scotland and Ireland," as we learn from an official source, "were supplied by the smuggler." The duties were reduced to 7s. per gallon in England, and to 2s. 4¾d. in both the other countries. "The result of these changes was a most surprising increase of legally-made spirits. In 1820 the quantity made in the United Kingdom, and retained for home consumption, was 9,600,000 gallons. In 1826"—two years after the change of duties—"it was 18,200,000" (*First Report of Commissioners of Inland Revenue*, 1857). At subsequent periods, when the duties were again moderately increased, it was found that there was a sharp limit to the process, and that the excise on spirits could not be advanced much beyond 3s. 4d. in Scotland and Ireland without a revival of the old evils and a decline of revenue; while in England more than 7s. encouraged adulteration, and much higher prices than were justified by the duty and other trade charges. Later experience shows that this check is elastic. Since 1860 the excise on home-made spirits has been 10s. per gallon uniformly in the three kingdoms, and yet in no previous period have there been fewer complaints of smuggling or illicit distillation. This result is ascribable to various causes. The increase of employment, higher wages for legitimate labor, the opening of all parts of the country by means of communication, the greater sway of the law, and the greater influence of habits of order, must have discouraged the dark though tempting business of smuggling quite as much or more than the enormously high excise encouraged it. The excise service itself has also been much improved, and by simple mechanical provisions in the distilleries much less supervision of officers is requisite, with greater security against fraud than in former times. The exemption from duty of methylated spirit, used extensively in "French polishing" and many other arts, has likewise had a beneficial effect in stamping out illicit distillation. The spirit of wine, or pure alcohol of the druggists, however, is still almost necessarily subject to duty, though it were certainly desirable that in tinctures and other medicaments incapable of being abused as potable liquors, it should be free of tax. But permission to prepare tinctures in bond, in quantities of not less than nine gallons, has not as yet been taken advantage of to any extent. In the export of spirit of wine a rebate of duty is allowed.

The duty on malt, like that on spirits, has also for some years been uniform in the United Kingdom, at the rate of 2s. 7½d. per bushel, with a further duty on brewers of 12s. 6d. for every 12½ quarters mashed, or, what is held equivalent, every 50 barrels of 36 gallons brewed. The duty on each gallon of ale is thus barely one and seven-eighths of a penny—a very lenient excise compared with the 10s. per gallon on spirits. It might be supposed that when the duty on spirits in Scotland and Ireland was made as high as in England, a certain equality should have been established in the incidence of taxation on the liquors most generally used in the several countries. But the legislature has favored the milder fermented liquors with the view of promoting temperance in all parts of the kingdom, irrespective of taste, habit, or climate. How far this good intention has been realized is a question aside from these explanatory remarks on excise. It has only to be observed that while the consumption of brewed liquors has been increasing in Scotland, the consumption of distilled spirits in England has been increasing in a still greater proportion. The following are the official returns of spirits and malt charged with duty in the three kingdoms in 1867 and 1876:—

	England.		Scotland.		Ireland.	
	1867.	1876.	1867.	1876.	1867.	1876.
Spirits at proof, gallons..	9,170,561	13,368,096	7,144,144	9,193,608	6,377,648	8,156,743
Malt, bush'ls	43,608,570	54,161,922	2,381,501	3,021,891	2,499,366	3,342,869

The abolition of many of the old excise duties, and consequent simplification of the department, prepared the way for an administrative reform, by which the three revenue branches of excise, stamps, and taxes were placed under the superintendence of one board of commissioners, and included in the general description of inland revenue. This was accomplished in 1848, and the board of excise left its old head-quarters in Gresham House and was merged in the new body in Somerset House, by which the collection and management of the whole inland revenue has since been directed. The provisions for the consolidation and guidance of the board of inland revenue are embodied in the Act 12 Vict. cap. 1. The numerous statutes of excise, well annotated, have been collected and published under the authority of the commissioners of inland revenue, in one volume (1873). (R. SO.)

EXCOMMUNICATION, the highest ecclesiastical censure, is the judicial exclusion of a baptized person from the fellowship of the visible church of Christ. As part of the discipline of the church it is based on the precept of Christ (Mat. xvi. 19, xviii. 15–18; John xx. 23), and on apostolic example (1 Cor. v. 5; 1 Tim. i. 20, etc.). These and the other texts, however, bearing, or supposed to bear, on the subject of excommunication, have not by any means been uniformly interpreted; and the usages ostensibly based on them have differed accordingly. The praxis of Christian discipline, moreover, has never been wholly independent of Jewish and pagan influences; and its variations cannot be adequately explained unless account be taken of several non-Christian analogues of excommunication. Among other pagan analogues may be mentioned the Greek *χερνίβων εἰργεσθαι* (Demos. 505, 14), with its consequences (Æsch., *Choeph.* 283; *Eum.* 625 f.; Soph., *Œd. Tyr.* 236 ff.); the Roman *exsecratio* and *diris devotio;* the awful power which the Druids claimed of excluding from the sacrifices (Cæs., *B. G.*, vi. 13). But more influential than any of these has been the ancient Jewish practice. The word used in the New Testament to describe an excommunicated person, *ἀνάθεμα* (1 Cor. xvi. 22; Gal. i. 8, 9; Rom. ix. 3), is the constant LXX. rendering of the Hebrew חֵרֶם (see ANATHEMA). This word (ḥerem), in its primary signification, means simply any person or thing separated or set apart, a meaning which is still seen in the familiar Arabic word "harem." The connection in thought between the notions separation from common use, dedication to God, and devotion to destruction is not very obscure, and it soon established itself in the Hebrew mind. In Lev. xxvii. 21, 28, 29, we read that no "devoted" person or thing was to be sold or redeemed; "none which shall be 'devoted' from among men shall be redeemed, but shall surely be put to death." The Hebrew *mohoram* (devoted) was precisely in the same position as the Latin *impius* or *sacer* (Mommsen, *Röm. Alt.*, ii. 50 ff.). In Num. xxi. 2, 3, Deut. ii. 34, iii. 6, vii. 2, we find whole cities or nations thus "banned," "excommunicated," or devoted to destruction. We occasionally read of Israelites as well as of aliens falling under this ban (*e.g.*, in Judg. xxi. 5, 11); indeed, the extreme penalty of being "cut off," which is attached to so many sins, appears to have been carried into effect by the congregation only after the חֵרֶם had been duly pronounced by the competent authority (Ex. xxii. 19 [20]; Deut. xiii. 7–18 [6–17]; *cf.* Ewald, *Alterth.*, pp. 101, 420). If in this חֵרֶם we already find the analogue of the major excommunication (called anathema) of the mediæval church, we may perhaps look for the analogue of the minor in that temporary separation or seclusion (niddah) which was prescribed for ceremonial uncleanness. Scripture furnishes no distinct trace of the use of the deadly anathema in post-exile times; it is probable, however, that the right of sentencing by a חֵרֶם to capital punishment remained with the Jewish ecclesiastico-civil authorities to a very late period (Ezra vii. 25, 26). In Ezra x. 8, it ought to be observed, we read of an excommunication of a milder kind; its effect was that all the substance of the offender was "forfeited" (*i.e.*, laid under a herem), but he himself merely "separated" from the congregation.

The Talmud recognizes two kinds of excommunication, a minor and a major, called respectively niddui and herem. The niddui (from *niddah*, to drive away) could be pronounced at any time by any competent individual (*cum periculo*, of course); its validity continued for thirty days, during which period the subject of it was expected to go into mourning, absent himself from the synagogue, and separate himself from all his fellows by a distance of not less than four ells. He was not excluded from the temple, but if he visited it he was required to enter by a separate door. If at the end of thirty days he showed impenitence or contumacy, the niddui might be renewed once and again; and finally, in certain circumstances, the herem might be pronounced. A valid herem, which could only be pronounced by a court of not less than ten judges, had the effect of excluding from the temple as well as from the synagogue, and from all association with the faithful. Some writers have asserted that there was a still more terrible, because irrevocable, sentence called the shammatta; but the preponderance of evidence is against this statement. (See Buxtorf's *Lexicon*, p. 2466; and Selden, *De Jure Nat. et Gen.*, iv. 9.) Among modern instances of expulsion from the Jewish communion, that of Spinoza (16th July, 1656) for contempt of the law has become famous. The text of the curse pronounced upon the culprit, which is similar to that given by Selden (as above, iv. 7), may be taken as a fair specimen of the formulæ then in use. The *Exemplar Humanæ Vitæ* of Uriel d'Acosta may also be referred to.

As an authority upon Jewish usages the Talmud does not go nearly so far back as to the beginning of the first Christian century. It is to the New Testament alone that we must look for any little information that can be had on the contemporary practice of the Jewish courts. The sentence of exclusion from the synagogue is plainly indicated in Luke vi. 22, John ix. 22, xii. 42, and the more severe sentence seems to be hinted at in John xvi. 2. The question as to the period at which the Jewish synedrium ceased to have the power of giving full effect to the herem spoken of in Leviticus, has been much disputed. The Talmud itself says that the judgment of capital causes was taken away from Israel forty years before the destruction of the temple. But the point whether the synedrium which tried Jesus Christ could lawfully claim that power is still unsettled.

It has been already said that the use of excommunication as a part of Christian discipline, is based on the precept of Christ and on the apostolic practice. The general principles which ought to be observed can be easily gathered from the New Testament writings; but the church appears to have been left, for most of the practical details, to the guidance of reason and experience. Mat. xviii. 17 leaves unsolved many questions which cannot fail to arise as to the occasion, nature, and effects of excommunication. Tit. iii. 10, which enjoins the "rejection" (comp. 1 Tim. iv. 7) of a "heretic" after two "admonitions," can hardly be called more explicit. The *locus classicus* is 1 Cor. v. taken in connection with 1 Tim. i. 20. In the former passage, much importance has been attached to the apparent distinction between the *αἱρειν ἐκ μέσου* in vs. 2, 13, and the *παραδοῦναι τῷ Σατανᾷ* in v. 5, the former being (it is alleged) within the competency of the congregation, and the latter a purely apostolic function. The *ἀνάθεμα*, or "delivering over to Satan for the destruction of the flesh," has been the subject of much dispute (see Bingham, *Antiq.*, xvi. 2, 15). The language may safely be assumed to have been borrowed from an older formula. Plainly it was intended as the highest censure, to be pronounced only on grave offenders. It is also manifest that it was not irrevocable, and that it was in every case meant to have a salutary disciplinary effect upon the soul.

The writings of the church fathers give sufficient evidence that two degrees of excommunication, the *ἀφορισμός* and the *ἀφορισμὸς παντελής*, as they were generally called, were in use during, or at least soon after, the apostolic age. The former, which involved exclusion from participation in the eucharistic service and from the eucharist itself, though not from the so-called "service of the catechumens," was the usual punishment of comparatively light offences; the latter, which was the penalty for graver scandals, involved "exclusion from all church privileges,"—a vague expression which has sometimes been interpreted as meaning total exclusion from the very precincts of the church building (*inter hiemantes orare*), and from the favor of God (Bingham, xvi. 2, 16). For some sins, such as adultery, the sentence of excommunication was in the 2d century regarded as *παντελής* in the sense of being irrevocable. Difference of opinion as to the absolutely "irremissible" character of mortal sins led to the important controversy associated with the names of Zephyrinus, Tertullian, Callistus, Hippolytus, Cyprian, and Novatian, in which the stricter and more montanistic party held that for those who had been guilty of such sins as theft, fraud, denial of the faith, there should be no restoration to church fellowship even in the hour of death. On this point the provincial synods of Illiberis (Elvira) in 305 and of Ancyra in 315 subsequently came to conflicting decisions. But the excommunication was on all hands regarded as being "medicinal" in its character. It is noteworthy that the word *ἀνάθεμα* had fallen into disuse about the beginning of the 4th century, and that, throughout the same period, no instance of the judicial use of the phrase *παραδοῦναι τῷ Σατανᾷ* can be found.

A new chapter in the history of church censure may be said to have begun with the publication of those imperial edicts against heresy, the first of which, *De summa trinitate et fide catholica*, dates from 380. Till then exclusion from church privileges had been a spiritual discipline merely; thenceforward it was to expose a man to serious temporal risks. Excommunication still continued to be occasionally used in the spirit of genuine Christian fidelity, as by Ambrose in the case of Theodosius himself (390); but the temptation to wield it as an instrument of secular tyranny too often proved to be irresistible. In the formula used by Synesius (410), which is to be found in Bingham and in most other works of reference, we already find the attention of magistrates specially called to the censured person. The history of the next thousand years shows that the magistrates were seldom slow to respond to the appeal. Even the hastiest survey of that long and interesting period enables the student to notice a marked development in the theory and practice of excommunication. One or two points may be specially noted. (1.) While it had been held as an undoubted principle by the ancient church that this sentence could only be passed on living individuals, whose fault had been distinctly stated and fully proved, we find the mediæval church on the one hand sanctioning the practice of excommunication of the dead (Morinus, *De Pœnit.*, x., c. 9), and, on the other hand, by means of the papal interdict, excluding whole counties and kingdoms at once from every church privilege. The earliest well-authenticated instance of such an interdict is that which was passed (998) by Pope Gregory V. on France, in consequence of the contumacy of King Robert the Wise. Other instances are those laid respectively on Germany in 1102 by Gregory VII. (Hildebrand), on England in 1208 by Innocent III., on Rome itself in 1155 by Adrian IV. (2.) While in the ancient church the language used in excommunicating had been carefully measured, we find an amazing recklessness in the phraseology employed by the mediæval clergy. The curse of Ernulphus or Arnulphus of Rochester (cir. 1100), which has been made familiar to most students of English literature, is a very fair specimen of that class of composition. With it may be compared the formula transcribed by Dr. Burton in his *History of Scotland* (iii. 317 ff.). To the spoken word was added the language of symbol. By means of lighted candles violently dashed to the ground and extinguished the faithful were graphically taught the meaning of the greater excommunication,—though in a somewhat misleading way, for it is a fundamental principle of the canon law that *disciplina est excommunicatio, non eradicatio*. The first instance, however, of excommunication by "bell, book, and candle" is comparatively late (cir. 1190).

At the Reformation the necessity for church discipline did not cease to be recognized; but the administration of it in many Reformed churches passed through a period of some confusion. In some instances the old episcopal power passed more or less into the hands of the civil magistrate (a state of matters which was highly approved by Erastus and his followers), in other cases it was conceded to the presbyterial courts. In the Anglican Church the bishops (subject to appeal to the sovereign) have the right of excommunicating, and their sentence, if sustained, may in certain cases carry with it civil consequences.

In the law of England sentence of excommunication, upon being properly certified by the bishop, was followed by the writ *de excommunicato capiendo* for the arrest of the offender. The statute 5 Eliz. c. 23 provided for the better execution of this writ. By the 53 Geo. III. c. 127 (which does not, however, extend to Ireland) it was enacted that "excommunication, together with all proceedings following thereupon, shall in all cases, save those hereafter to be specified, be discontinued." Disobedience to or contempt of the ecclesiastical courts is to be punished by a new writ *de contumace capiendo*, to follow on the certificate of the judge that the defender is contumacious and in contempt. Sect. 2 provides that nothing shall prevent "any ecclesiastical court from pronouncing or declaring persons to be excommunicate on definite sentences pronounced as spiritual censures for offences of ecclesiastical cognizance." No person so excommunicated shall incur any civil penalty or incapacity whatever, save such sentence of imprisonment, not exceeding six months, as the court shall direct and certify to the Queen in Chancery.

In Scotland, three degrees of church censure are recognized—admonition, suspension from sealing ordinances (which may be called temporary excommunication), and excommunication properly so called. Intimation of the last-named censure is occasionally (but very rarely) given by authority of a presbytery in a public and solemn manner, according to the following formula:—"Whereas thou N. hast been by sufficient proof convicted of (here mention the sin), and after due admonition and prayer remainest obstinate without any evidence or sign of true repentence: Therefore in the name of the Lord Jesus Christ, and before this congregation, I pronounce and declare thee N. excommunicated, shut out from the communion of the faithful, debar thee from privileges, and deliver thee unto Satan for the destruction of thy flesh, that thy spirit may be saved in the day of the Lord Jesus." This is called the greater excommunication. The congregation are thereafter warned to shun all unnecessary converse with the excommunicate. (See *Form of Process*, c. 8.) Formerly excommunicated persons were deprived of feudal rights in Scotland; but in 1690 all Acts enjoining civil pains upon sentences of excommunication were finally repealed (Burton's *History*, vii. 435). (J. S. BL.)

EXECUTORS AND ADMINISTRATORS, in the law of England, are those on whom the personal property of a deceased person devolves, according as he has or has not left a will. If a man dies and leaves a will, the person or persons named therein to carry out his intentions are his executors, and their title to the personality vests at the moment of the testator's death. If there is no will, the right of administering the personal estate of the deceased is granted, according to certain rules, by the court of probate to persons who are called administrators. When the will contains no nomination of executors, administration is said to be granted "with the will annexed." The title of the administrator vests at the date of the letters of administration. As to the appointment of executors and administrators before the establishment of the Court of Probate, see articles WILL and INTESTACY. The executors or administrators when appointed become the legal personal representatives of the deceased. As to powers and duties administrators stand in the same position as executors.

It is the duty of an executor—(1) to bury the deceased in a manner suitable to the estate he leaves behind him; extravagant expenses will not be allowed, but the payment of legitimate funeral expenses "takes precedence of any debt or duty whatsoever;" (2) to obtain probate of the will (or letters of administration) within six months after the death. (3) He must make an inventory of the personal estate of the deceased, whether in possession or outstanding, and this inventory he is to deliver to the court on oath. He is to collect all the goods so inventoried and to commence actions which may be necessary to recover those which are outstanding. The executor is responsible to creditors for the whole of such estate, whether in possession or in action. (4) He must pay the debts of the deceased according to their several degrees of priority. An executor can, however, pay any debt due to himself by retaining it out of the fund before the other creditors are paid, except in the case of an *executor de son tort.* And a creditor only gains a preference for himself over others of the same class by taking action and obtaining judgment for his debt. If the estate is exhausted by due and proper payments before all the debts are cleared off, the unsatisfied creditors cannot recover. (5) After the debts come the *legacies*, which must be paid as far as the estate will extend. An executor cannot exercise a preference in the payment of his own legacy. (6) The residue of the estate must be paid to the person named in the will as residuary legatee. If there is no will or no residuary legatee named, the residue falls to be distributed among the next of kin, under the statute of distributions (see INTESTACY). It was held at one time that in default of a residuary legatee the residue fell to the executor himself, but now nothing less than the expressed intention of the testator can give it to him.

An executor *de son tort* (of his own wrong) is one who intermeddles with the estate of a deceased without authority. He thereby makes himself liable to all the trouble of an executorship without any of its profits.

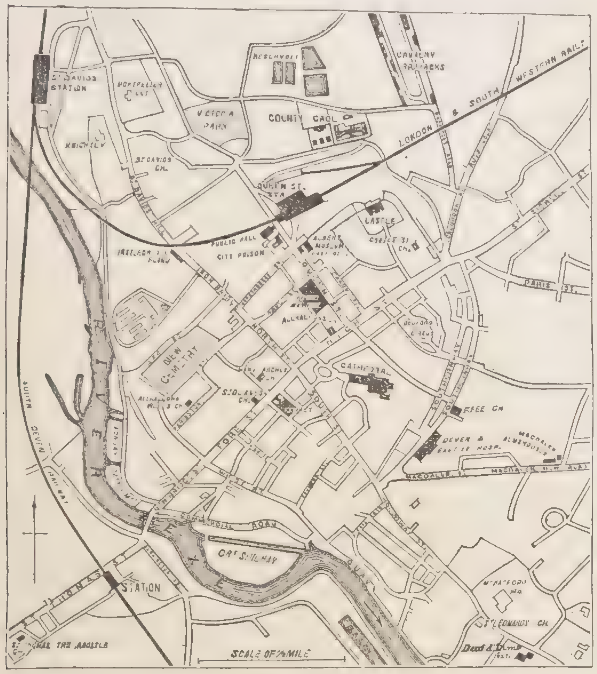
If an executor is under age or abroad when he is appointed, temporary administration *durante minore ætate*, or *durante absentia*, may be granted to another.

An executor of an executor becomes the executor of the first testator. If, however, an executor dies intestate before completing the administration of the estate, an administrator *de bonis non* must be appointed. This is also the case where an administrator dies before the administration is complete. (E. R.)

EXELMANS, RENY JOSEPH ISIDORE (1775–1852), a distinguished French general, was born at Bar-de-Duc, November 13, 1775. He volunteered into the 3d battalion of the Meuse in 1791, became lieutentant in 1797, and in 1798 was attached as aide-de-camp to General Eblé. In his first campaign in Italy he greatly distinguished himself; and in April, 1799, he was rewarded for his services by the grade of captain in the 16th regiment of dragoons. In the same year he took part with honor in several battles connected with the conquest of Naples, and was promoted to the rank of major; and in 1801 he became aide-de-camp to General Murat. He was named chief of a squadron in 1803, and he accompanied Murat in the Austrian, Prussian, and Polish campaigns of 1805, 1806, and 1807. At the passage of the Danube, and in the battle of Wertingen, he specially distinguished himself; he was made colonel of the 1st regiment of chasseurs for the valor which he displayed at Austerlitz; and after the battle of Eylau in 1807 he obtained the rank of brigadier-general. In 1808 he accompanied Murat to Spain, but was there made prisoner and conveyed to England. On regaining his liberty in 1811 he went to Naples, where King Murat appointed him grand master of horse; but when Murat became estranged from Napoleon, Exelmans left his court and joined the French army. Napoleon was then entering on his Russian campaign, and gave him welcome and immediate employment as a general of division. He was present at the battle of Moscow, and in the famous retreat from that city his steadfast courage was conspicuously manifested on several occasions. In 1813, he received, for services in the campaign of Saxony, the decoration of the Legion of Honor; and in 1814 he reaped additional glory by his intrepidity and skill in the campaign of France. When the Bourbons were restored in 1815 he retained his position in the army, but this did not prevent Napoleon on his return from Elba from intrusting him with the command of the 2d army corps. After the second Restoration he was proscribed, and lived in Belgium, and subsequently in Nassau, till 1819, when he was recalled to France. In the following year he was appointed to an inspector-generalship of cavalry; and after the July revolution of 1830 he received from Louis Philippe the grand cross of the Legion of Honor, and was created a peer of France. In the House of Peers he denounced the execution of Marshal Ney as an "abominable assassination." At the revolution of 1848 Exelmans was one of the adherents of Louis Napoleon; and in 1851 he was, in recognition of his long and brilliant military career, raised to the dignity of a marshal of France. His death, 10th July, 1852, was the result of a fall from his horse.

EXETER, the chief town of Devonshire, in England, a city which is a county in itself, and a municipal and parliamentary borough, stands on the Exe, about ten miles northwest of the mouth of the river, where it opens to the English Channel. The distance of Exeter from London is 194 miles. The ancient city (round which suburbs have extended) occupies a broad ridge of land, which rises steeply from the left bank of the Exe. At the head of the ridge is the castle, on the site of a great British earthwork. This was the stronghold of *Caer Isc* (so named from the river Isc or Exe, meaning water); and the British town became the *Isca Damnoniorum* of the Romans, just as Isca Silurum was the Roman name of Caerleon on the *Usk*, in South Wales. Roman coins, tesselated pavements, pottery, and sepulchral urns have been found from time to time, proving that the station was one of importance. It was one of the few cities in Britain which were not deserted at the time of the Saxon Conquest; and when Athelstan came westward about 926, he found *Exanceaster*, the "chester" or fortified town on the Exe, as the Saxons called it, occupied by Britons and Saxons *æquo jure.*

The ground plan of the city indicates its Romano-British origin, since the principal streets cross each other nearly in the centre. The main or High Street is, in fact, a portion of the Roman road which extended from the eastern border of the county to the Tamar. Exeter was more than once attacked by the Northmen; but the walls which had been constructed by Athelstan greatly protected the "burgh;" and in 1050 the episcopal see of Devonshire, which had been founded at Crediton about 910, was removed, for greater security, to Exeter.



Plan of Exeter.

The position of Exeter, and its importance as the principal city of the western peninsula, have affected the whole course of its history, and led to its numerous sieges. In 1068 the Conqueror appeared before Exeter, beleaguered it for eighteen days, and then received the submission of its citizens. He afterwards founded the castle, known as "Rougemont," from the red color of the rock on which it stands. The castle was held for Matilda in 1137 by Baldwin de Redvers, earl of Devon; and King Stephen took it after a siege of three months. Exeter was Lancastrian, and in 1469 held out successfully against Sir William Courtenay and the Yorkists. In 1497 it was besieged by Perkin Warbeck, and in 1549 for thirty-five days by the men of Devon and Cornwall, who rose in defence of the "old religion." The city was taken and retaken during the civil war; and the queen gave birth there to the Princess Henrietta, afterwards duchess of Orleans. After that period the most noticeable event is the entry of the prince of Orange (William III.) in November, 1688. His "declaration" was then read by Burnet in the cathedral.

The High Street of Exeter and its continuation, called Fore Street, are narrow, but very picturesque, with many old houses of the 16th and 17th centuries. There is a tangle of lesser streets within the walls, the line of which may be traced. All the gates have been destroyed. The suburbs, which have greatly extended since the beginning of the present century, contain many good streets, terraces, and detached villas. The surrounding country is not only rich and fertile, but is of great beauty. Extensive views are commanded in the direction of Haldon, a stretch of high moorland which may be regarded as an outlier of Dartmoor. The lofty mound of the castle has been laid out as a promenade, with fine trees and broad walks. The city is the centre of the system of western railways. London may be reached either by the Great Western (Bristol and Exeter) line, or by the South-Western, passing by Salisbury and Basingstoke. The distance in both cases is about the same. The North Devon railway runs from Exeter by Crediton to Barnstaple and Ilfracombe; and the South Devon by Teignmouth and Totness to Plymouth, and thence into Cornwall. There is also a line to Plymouth belonging to the South-Western Company, which passes inland by Lidford and Tavistock.

The population of Exeter in 1871 was 34,650 within the municipal limits. The parliamentary borough contained 44,226 persons. The city, of which the earliest recorded charter was granted by Henry I., has returned two members of parliament since the reign of Edward I. It is situated in the parliamentary division of East Devon. Assizes for the county of Devon are held twice in the year at Exeter, in the assize hall within the castle. The most important buildings in the city are the cathedral, the guild hall, and the Albert Memorial Museum; and the remains of the castle are also of interest.

Corporation Seal.

The cathedral, although not one of the largest in England, is inferior to none in the great beauty of its architecture and in the richness of its details. With the exception of the Norman transeptal towers, the general character is Decorated, ranging from about 1280 to 1369. On the exterior the great peculiarities are the towers mentioned above, and the west front, which is of later date than the rest of the church (probably 1369-1394), and is adorned with statues. Transeptal towers occur elsewhere in England only in the collegiate church of Ottery, in Devonshire, where the cathedral served as a model. Within, the points to be specially noted are—the long unbroken roof, extending throughout nave and choir (there is no central tower or lantern); the beautiful sculpture of bosses and corbels; the minstrel's gallery, projecting from the north triforium of the nave; and the remarkable manner in which the several parts of the church are made to correspond. The window tracery is much varied; but each window answers to that on the opposite side of nave or choir; pier answers to pier, aisle to aisle, and chapel to chapel, while the transeptal towers complete the balance of parts. A complete restoration of the cathedral, under Sir G. G. Scott, was begun in 1870 and completed in 1877. The new stall work, the reredos, the choir pavement of tiles, rich marbles, and porphyries, the stained glass, chiefly by Clayton and Bell, and the sculptured pulpits in choir and nave are of the highest merit. The ancient episcopal throne, a sheaf of tabernacle work in wood, erected by Bishop Stapledon about 1320, has been cleaned and renovated; and the organ, of which the pipes are of very nearly pure tin, has been rearranged. The most interesting monuments are those of bishops of the 12th and 13th centuries, in the choir and lady chapel. Some important MSS., including the famous book of Saxon poetry given by Leofric to his cathedral, are preserved in the chapter house. The united sees of Devonshire and Cornwall were fixed at Exeter from the installation there of Leofric (1050) by the Confessor, until the re-erection of the Cornish see in 1876.

Arms of Bishopric.

The Guildhall in the High Street is a picturesque Elizabethan building, which contains some interesting portraits. Among them are a full-length of General Monk, duke of Albemarle, born in Devon (engraved in Lodge), and a full length (given by Charles II.), of the Princess Henrietta. Both are by Sir Peter Lely. The Albert Memorial Museum in Queen Street was designed by Hayward of Exeter (1865). Devonshire materials have been chiefly used in its construction. The building, which is of considerable size, contains a school of art, an excellent free library, a reading-room, and a museum of natural history and antiquities. There is a good collection of local birds, and some remarkable pottery and bronze relics extracted from barrows near Honiton or found in various parts of Devonshire. Of the castle the chief architectural remain is a portion of a gateway tower which may be late Norman. Huge dykes and trenches of the British period exist in an adjoining garden. The parish churches of Exeter are of small importance, but the modern church of St. Michael (1860) deserves notice. It is sufficient to mention the Devon and Exeter Institution, founded in 1813, which contains a large and valuable library; the diocesan training college and school; and the grammar school, which dates from the reign of Henry VIII. There are two market houses in the city, many hospitals, and many charitable institutions.

Exeter has few manufactures; and Devonshire or Honiton lace, for which it is celebrated, is made quite as much in the villages of the south coast as in and around Exeter itself, although it is chiefly brought to the city for sale. There is a considerable trade of a miscellaneous description. Hides from South America, wines from Portugal and Spain, fruits and valonia from the Mediterranean, and coal from the northern counties and Wales are imported. Leather, paper, corn, and cider are sent to London and other parts of the country. The woollen trade has quite passed away from Exeter, although it was at one time so considerable that it was only exceeded by that of Leeds, and the value of exported goods in 1768 exceeded half a million annually. The Ship Canal, from Exeter to Topsham, in the estuary of the Exe, greatly assisted this commerce. It was begun in 1564, enlarged in 1675, and again in 1827. Vessels of 300 tons can come up to the quay at Exeter; those of greater burden remain at Topsham; and those of the largest size lie at Exmouth, at the outfall of the river.

Bibliography.—Of older histories the most important is Izacke's *Antiquities of Exeter*, 1681. The best later authorities are *The History of the City of Exeter*, by the Rev. G. Oliver, 1861; *Lives of the Bishops of Exeter and History of the Cathedral*, by the Rev. G. Oliver, 1861; Archdeacon Freeman's *History of Exeter Cathedral*, 1874; and Murray's *Handbook for the Southern Cathedrals of England* (Exeter), see edition of 1876.

(R. J. K.)

EXHIBITIONS. National and International Exhibitions may be ranked among the most remarkable features in the industrial records of the world, and have taken their place as prominent instruments of civilization, for by their means the diffusion of knowledge has been advanced and extended in the most wonderful manner.

It is to the Society of Arts that the credit is due of having originated national exhibitions. So far back as the year 1761 that body offered prizes for agricultural and other machines, and had an exhibition of these in its apartments. In 1798 France began a series of national expositions under the direction of Napoleon. The exhibitors at first numbered only 110, and a jury of nine was appointed to decide upon their merits. A gold medal was offered to the manufacturer who should deal the heaviest blow to English trade. The second exposition took place in 1801, and was so successful that the third was fixed to take place in 1802. Expositions were subsequently held in 1806, 1819, 1823, 1827, 1834, 1839, 1844, and in 1849, in which year there were 4494 exhibitors. This last was the conclusion of the purely national displays in France before the great London international exhibition of 1851. So exclusive were the French at that time that a proposal made for the representation of foreign products in 1849 was deemed by the minister of commerce to have emanated from the enemies of French industry.

In 1820 a series of exhibitions were opened in various cities of Austria, and national exhibitions were held at Vienna in 1835, 1839, and 1845, which last had 1865 exhibitors. In Germany there were national exhibitions at Berlin in 1822 and 1827, and in 1844 one with 3060 exhibitors. National exhibitions were held in Saxony between 1824 and 1845, in which last year there were 6013 exhibitors. Between 1837 and 1848 exhibitions were held at Lausanne, Bern, St. Gall, and Zurich in Switzerland; between 1835 and 1850 at Brussels and Ghent in Belgium; between 1823 and 1844 at Stockholm in Sweden; between 1829 and 1849 at St. Petersburg, Moscow, and Warsaw in Russia; between 1844 and 1849 at Lisbon in Portugal; between 1829 and 1855 in the kingdom of Sardinia; between 1827 and 1850 at Madrid; between 1828 and 1844 at New York and Washington in the United States.

In the United Kingdom industrial displays had to fight their way against much apathy and prejudice. In 1828 an exhibition was formed in London under the patronage of George IV., which dragged out an unfortunate existence till 1833, when it was consigned to oblivion as an unsuccessful bazaar. In Ireland exhibitions of native industry were held triennially in the rooms of the Royal Dublin Society, commencing in 1829. In 1845, however, an exhibition of manufactures held in Covent Garden, London, proved a great success; and in 1849 an exposition of industry was held at Birmingham, which was the most complete of any held till that time in the country.

After various proposals made by the Society of Arts between 1846 and 1849, it was held that the great object of an international exhibition of industry was more likely to be carried out than hitherto, and at last a royal commission was issued to take steps for an industrial exhibition to be held in 1851. The commissioners received a site of upwards of 18 acres in Hyde Park, and erected the building known as the "Crystal Palace," from the designs of Mr. (afterwards Sir) Joseph Paxton. Its general plan was a parallelogram 1848 feet long by 408 feet wide. There was also a projection on the north side 936 feet long, the whole covering a space of 1,000,000 square feet. The exhibition had four great departments,—raw material, machinery, manufactures, fine arts,—which were subdivided into 30 classes; and this arrangement has been usually followed in the great exhibitions since held. In allocating the space for the display of objects one-half was given to England and the colonies, the other half to foreign countries. The estimated value of the articles exhibited, excluding the famous Koh-i-noor diamond, was £1,781,929. This exhibition was opened on 1st May by Queen Victoria in person, and was closed on 11th October following, and the receipts exceeded the expenditure by a sum of £213,305. The building was afterwards removed to Sydenham, where it forms the main part of the present "Crystal Palace."

The success of the Great Exhibition of 1851 encouraged the repetition of similar displays all over the world, a list of which will be found in the table given below.

In 1855 the great Paris international exhibition was held, which was opened by the emperor of the French on 17th May. The buildings for this exhibition were of various kinds. There were the palais d'industrie, the palais des beaux arts, and the panorama; erections were afterwards added for agricultural implements, carriages, minor articles, etc. The main building, which was of stone, brick, and glass, was only 800 feet long by 350 feet wide. This exposition brought together an assemblage of objects in the industrial and fine arts such as had never been seen before. The distinguishing feature of the palais d'industrie was its collection of the works of living artists, while the London exhibition of 1851 was principally a display of manufactured goods. The exposition was closed on the 15th November when the distribution of medals to about 12,000 exhibitors took place.

In 1862 the second great English international exhibition was held in London in an immense brick erection adjoining the gardens of the Horticultural Society at South Kensington. The building consisted of two vast domes of glass, 250 feet high and 60 feet in diameter, larger than the dome of St. Peter's, connected by a nave 800 feet long, 100 feet high, and 83 feet wide, with a closed roof lighted by a range of windows after the manner of the clerestory of a Gothic cathedral. The domes opened laterally into spacious transepts, and the nave into a wide central avenue and interminable side aisles and galleries roofed with glass. These apartments occupied 16 acres, but in addition there were two *annexes* which covered 7½ acres. The ceremonial with which this exhibition was inaugurated on 1st May was the most imposing public pageant which had been seen in Britain for many years. The number of exhibitors in the industrial division was 26,348, besides 2305 in art, making in all 28,653. The fine art collection was very extensive, comprising 901 pieces of sculpture, 1275 engravings, 983 architectural designs, and no less than 3370 paintings. The classification of the objects was based upon that of 1851, and embraced 36 divisions, in addition to those of the fine arts.

In April, 1867, a great international *exposition universelle* was opened in Paris in an immense oval building erected in the Champ de Mars. It was arranged in twelve concentric aisles, with a small open central garden. It covered no less than 37 acres, and the total number of exhibitors was 42,000. It was intended to bring into notice all the resources which industry can create for satisfying the requirements of mankind, and it was divided primarily into groups corresponding with the leading wants of the human family. A great feature was the display of actual examples of the styles of domestic and palatial architecture of most countries, even the tents of some of the nomad tribes, such as the Kirghis Tatars, Samoyeds, Bedouin Arabs, etc., being exhibited. In addition, all kinds of civil and military erections of general importance were represented.

In May, 1873, an international exhibition was opened in the Imperial Park at Vienna. The building in which it was held was of enormous size, covering about 40 acres. The principal part of the edifice was a grand nave nearly 1000 yards long, in the midst of which rose a vast rotunda or dome of great height. In this part of the building objects of a trophy character were exhibited, and presented a *coup d'œil* of surpassing grandeur. An immense number of prizes and diplomas were distributed, and the awards were shared by almost every nation in the world. This exhibition was closed in November, 1873. It was not a success, financially, there being a considerable deficit in the receipts. The building has been converted into a national museum.

Statistics of the First Six Great International Exhibitions.

	Acres.	Exhibitors.	Cost.	Days open.	Receipts.	Number of Visitors.
London of 1851	21	17,000	£292,794	144	£506,100	6,039,195
Paris of 1855	24½	21,779	1,000,000	200	128,099	5,162,330
London of 1862	23½	28,653	460,000	171	408,530	6,211,103
Paris of 1867	37	50,226	800,000	217	420,735	10,200,000
Vienna of 1873	40	42,584	2,200,000	186	206,470	7,254,687
Philadelphia of 1876	60	60,000	1,600,000	159	762,744	9,910,966

In 1876, after five years of preparation, the great international exhibition of America was opened in Fairmount Park, Philadelphia, on the 10th of May, being the centennial anniversary of the Declaration of Independence. The Main Building was in the form of a parallelogram extending east and west, 1880 feet in length and 464 feet in width. Its central span, in which was situated the grand avenue, was 1832 feet long by 120 feet wide, being the longest of such a width ever introduced into an exhibition building. The greater portion of the structure was one story high, the interior height being 70 feet. In the centre were four square towers 120 feet high. The frame work was of iron, filled in with glass and wood; it covered 20·02 acres. With the other buildings attached to the exhibition, a total space of 60 acres was covered. Besides the Main Building there were the Machinery Hall, the Horticultural Hall (built in a Moorish style), the Agricultural Hall, the Memorial Hall or Art Gallery, the Government Building, covering about 2 acres, in which were illustrated the functions of the Government in time of peace and its resources as a war power. Besides these there were the Women's Pavilion, the Judges' Hall, and a great many smaller erections, including a Swedish schoolhouse, a timber-framed house somewhat in the style of the 16th century, which formed the headquarters of the British commission. A structure having the homely designation of "Department of Public Comfort" was used as a place of rest and convenience. The total number of buildings within the inclosure was over 160, and their cost was £1,600,000. The number of exhibitors was 60,000, derived from 37 nations. The promenades in the Main Building were 25 miles in length.

In England, after the great displays of 1851 and 1862, a feeling began to gain ground that as the activity and ingenuity of manufacturers and designers were constantly directed to fresh efforts, universal expositions would attain such gigantic proportions as to become quite unmanageable. A resolution was therefore come to by the British commissioners, as trustees of the fund derived from the proceeds of the great exhibition of 1851, that the objects suitable for exhibition should be divided into groups, and that exhibitions of selections from these groups should be held at more frequent intervals. A plan was then arranged for a series of exhibitions of the fine arts, recent scientific inventions and discoveries, and two or three branches only of mannfactures, providing at the same time for the representation of each distinct manufacture once in ten years. Exhibitions were accordingly held in 1871, 1872, 1873, and 1874, but at last it was found that they lost the attractiveness of novelty, and failed to draw the multitude of sight-seers who flocked to the great exhibitions of 1851 and 1862.

Notwithstanding these views of the British commissioners, an *Exposition Universelle* on a great scale was opened in Paris on 1st May, 1878, by the President, Marshal MacMahon. It is expected to unite the civilized world, as the sciences are represented as well as the arts. The building, or Industrial Palace, is an enormous erection in the Champ de Mars, consisting of a series of rectangular galleries in which each country has been allotted a division more or less important. Besides the main building, there are about a dozen *annexes* without the *enceinte* of the palace. Immediately across the Seine there is a second palace situated in the Trocadero (so named from a Spanish fort in the harbor of Cadiz, captured in 1823), amidst ornamental gardens with cascades. This is devoted to the fine arts and music, and is to remain a permanent monument of the exhibition. It contains a music gallery even larger than the Albert Hall, London. The space occupied by the exhibition is about 140 English acres; and the total expense has been announced by the minister of commerce as about £1,800,000 sterling.

The following table shows the minor exhibitions which have been held in various parts of the world from 1852 to the present time (1878):—

1852	Cork	Exhibition of Irish arts and manufactures.
1853	Dublin	Exhibition of Irish arts and manufactures with those of other countries.
"	New York	Industrial exhibition, which cost £200,000.
"	New Brunswick	Native industry.
"	Madras	" "
1854	Madrid	Industrial arts.
"	Munich	German industry.
"	Christiania	Norwegian arts and manufactures.
1856	Brussels	Belgian arts.
"	Edinburgh	Exhibition of Art Manufacture Associat'n.
1857	Manchester	Art treasures exhibition.
"	Bern	Swiss arts and manufactures; 2050 exhibitors.
1858	Sardinia	Italian industry.
"	New York	American industry.
1859	Hanover	Exhibition, with 296 exhibitors.
"	Rouen	Products of 12 northern departments of France.
"	Athens	National exhibition, with 947 exhibitors.
1860	St. Petersburg	Russian products.
1861	Florence	Fine art in Tuscany and Italian silk goods.
"	Haarlem	Dutch industries.
"	Brussels	Exhibition of articles of common use.
"	Victoria	Exhibition preliminary to London great exhibition of 1862.
1863	Constantinople	Turkish produce, and foreign machinery.
1864	Amsterdam	Dutch produce, art, and industry.
"	Bayonne	Industries connected with corn and wine.
"	Malta	Local art and industry.
"	Calcutta	Principally agriculture.
"	Lucknow	" "
"	London	First workingmen's exhibition.
1865	Dublin	Arts and manufactures, attracted 900,000 visitors.
"	Cologne	Agriculture and horticulture.
"	Boulogne	International fishery exhibition.
"	Sierra Leone	Industrial exhibition.
"	Oporto	Arts, manufactures, and agriculture; 3911 exhibitors.
"	Dunedin, New Zealand	Colonial produce.
"	Birmingham	Metals and trades.
"	Vienna	Workingmen's industrial exhibition.
"	London	" " "
"	Stettin	Exhibition of industry, with 1451 exhibitors.
"	Philadelphia	American produce.
1866	Stockholm	Scandinavian industries.
"	Brazil, Rio de Janeiro	Raw produce, with 2590 exhibitors.
"	Melbourne	Intercolonial exhibition, rich in specimens of minerals.
"	London	Workingmen's exhibition.
1867	The Hague	Fishery exhibition.
"	Agra	Industries of N. W. provinces of India.
1868	Havre	International maritime exhibition.
"	Santiago	Products of Chili.
1869	London	South London industr'l classes exhibition.
"	Amsterdam	Netherlands Society of Manufacturers; rich in objects of domestic economy.

1870	Berlin	Exhibition of drawing implements.
"	Turin	Italian products.
"	St. Petersburg	Russian industrial exhibition.
"	Gujerat	Indian cotton.
"	Sydney	Intercolonial exhibition, with 2914 exhibitors.
"	London	Workmen's international exhibition.
1871	"	First annual international exhibition at South Kensington.
"	Milan	Exhibition of selected branches of industry.
"	Naples	International maritime exhibition.
1872	London	Second annual international exhibition.
"	Dublin	Irish native produce and fine arts.
"	Copenhagen	Scandinavian art and industry; 4000 exhibitors.
"	Lyons	Agriculture, industrial products, and works of art.
"	Moscow	Exhibition on celebration of second centenary of Peter the Great, illustrative of the progress of Russia in manufactures.
"	Bogota	Products of South America.
1873	London	Third annual international exhibition.
"	"	Fourth and last annual international exhibition.
1874	Aberdeen	Exhibition of fungi; 7000 specimens shown.
"	Brussels	Industrial art.
1875	Paris	Agricultural machines and implements.
1876	London	Exhibition of needlework in Albert Hall.
"	"	Exhibition of bees, their produce, hives, and bee furniture, in Alexandra palace.
"	Paris	Applications of electricity.
"	Thurso	Exhibition of art and industry, and local antiquities.
"	Brussels	Exhibition of life-saving and hygienic apparatus.
"	Kioto, Japan	Exhibition of silks, bronzes, casques, wearing-apparel, etc., being the fifth of a series since 1872.
1877	London	Loan collection of scientific apparatus.
"	"	Caxton exhibition, illustrative of the art of printing.
"	"	Westminster and Pimlico working classes industrial exhibition.
"	Cape Town	International exhibition of manufactures of all kinds.
"	Hamburg	International dairy exhibition.
"	Ghent	Exhibition of industrial art.
1878	Ballarat	International exhibition.

An international exhibition is proposed to be held in 1879 at Melbourne, a city which in 1851 was a town of but 20,000 inhabitants.

Of the London Great Exhibition of 1851 an official catalogue was published the same year in 4 vols. 8vo, and in 1852 a volume of reports by the juries on the subjects in the 30 classes into which the exhibition was divided, in royal 8vo. A sumptuous edition of this catalogue on large paper was printed, of which copies were presented to distinguished personages and public libraries. Of the exhibition of 1862 an illustrated catalogue was printed by the commissioners the same year in 4 vols. 8vo. Of the Paris exposition held in 1855 there was an official catalogue published the same year; and a *Rapport sur l'Exposition Universelle* (also published) was presented by Prince Napoleon to the emperor in 1857. Of the exposition of 1867 there was published in London the same year a translation from the proof-sheets of the French official catalogue. Of the Vienna exhibition of 1873 there was an official illustrated general catalogue, with a large number of reports of the juries, etc. Of the Philadelphia exhibition there was an official catalogue printed in four languages—English, French, German, and Spanish; a series of reports and awards under the different groups into which the exhibition was divided is now being published. Besides the general catalogues of the great international exhibitions, there have been published an immense number of catalogues of the exhibits of the different countries at each, which are to be found available for reference in the South Kensington and other industrial museums. Various beautifully illustrated books, representing the works of art exhibited, have been published both in London and Paris; and one, *Études sur l'Exposition de 1878*, intended to be a complete record of the progress made in all the arts up to the present date is about to be issued under the direction of E. Lacroix. (J. SM.)

EXMOUTH, a market-town and watering-place in the county of Devon, England, is situated at the mouth of the Exe, 10 miles E.S.E. of Exeter. It was the first watering-place on the coast of Devon, and is frequented, not only for bathing, but also as a winter residence by those suffering under pulmonary diseases, as it is celebrated for the mildness of its climate, and is well sheltered from the N.E. and S.E. winds by some high hills which rise almost close behind it. The old town, originally only a fishing village, has been altered and improved by new buildings. It lies along the base of the Beacon hill. The new town is built along the slopes of the hill and consists of terraces and detached houses. The sides and walks in the neighborhood are remarkably beautiful, and the hill commands one of the finest views in the south of England. Exmouth possesses a handsome church, and has assembly rooms, baths, libraries, and other essentials of a fashionable watering-place. Its sea wall, which is 1800 feet long and 22 feet high, affords an admirable promenade. Near the town is a natural harbor, called the Bight. The population of Exmouth in 1871 was 5614.

Exmouth was early a place of importance, and in 1347 contributed 10 vessels to the fleet sent to attack Calais. It at one time possessed a fort or "castelet," designed to command the estuary of the Exe. This fort, which was garrisoned for the king during the civil war, was blockaded and captured by Colonel Shapcoate, in 1646.

EXMOUTH, Edward Pellew, Viscount (1757–1833), an English admiral, was descended from a family which came originally from Normandy, but had for many centuries been settled in the west of Cornwall. He was born at Dover, April 19, 1757. At the age of thirteen he entered the navy, and even then his smartness and activity, his feats of daring and his spirit of resolute independence awakened remark, and pointed him out as one specially fitted to distinguish himself in his profession. He had, however, no opportunity of active service till 1776, when, at the battle of Lake Champlain, his gallantry, promptitude, and skill, not only saved the "Carleton"—whose command had devolved upon him during the progress of the battle—from imminent danger, but enabled her to take a prominent part in sinking two of the enemy's ships. For his services on this occasion he obtained a lieutenant's commission, and the command of the schooner in which he had so bravely done his duty. The following year, in command of a brigade of seamen, he shared in the hardships and perils of the American campaign of General Burgoyne. In 1782, in command of the "Pelican," he attacked three French privateers inside the Isle of Bass, and compelled them to run themselves on shore—a feat for which he was rewarded by the rank of post-captain. On the outbreak of the French war in 1793, he was appointed to the "Nymphe," a frigate of 36 guns; and, notwithstanding that, for the sake of expedition she was manned chiefly by Cornish miners, he captured, after a desperate conflict, the French frigate "La Cléopâtre," a vessel of superior size to his own and better armed. For this act he obtained the honor of knighthood. In 1794 he received the command of the "Arethusa," and in a fight with the French fleet off the Isle of Bass he compelled the "Pomona" to surrender. The same year the western squadron was increased and its command divided, the second squadron being given to Sir Edward Pellew. While in command of this squadron he, on several occasions, performed acts of great personal daring; and for his bravery in boarding the wrecked transport "Dutton," and his promptitude and resolution in adopting measures so as to save the lives of all on board, he was in 1796 created a baronet. In 1798 he joined the Channel fleet, and in command of the "Impétueux," took part in several actions with great distinction. In 1802 Sir Edward Pellew was elected member of parliament for Dunstable, and during the time that he sat in the Commons he was a strenuous supporter of Pitt. In 1804 he was made rear-admiral of the blue, and appointed commander-in-chief in India, where, by his vigilance and rapidity of movement, he entirely cleared the seas of French cruisers, and secured complete protection to English commerce. He returned to England in 1809, and in 1810 was appointed commander-in-chief in the North Sea, and in 1811 commander-in-chief in the Mediterranean. In 1814 he was created Baron Exmouth of Canonteign, and in the following year was made K.C.B., and a little later G.C.B. When the dey of Algiers, in 1816, violated the treaty for the abolition of slavery, Exmouth was directed to attack the town. Accordingly, on the 26th August, he engaged the Algerine battery and fleet, and after a severe action of nine hours' duration, he set on fire the arsenal and every vessel of the enemy's fleet, and shattered her sea defences into ruins. At the close of the action the dey apologized for his conduct, and agreed to a renewal of the treaty, at the same time delivering up 1800 persons of various nations who had been Algerine slaves. For this splendid victory

Exmouth was advanced to the dignity of Viscount. Shortly before his death, which took place 23d January, 1833, he was made vice-admiral. A Life of Exmouth, by Edward Osler, was published in 1835.

EXODUS. See PENTATEUCH.

EXORCISM, the act of expelling evil spirits from persons or places by means of certain adjurations and ceremonies, appears in the present custom or past history of almost every nation of the world. Its importance is greatest among barbarous peoples, whose belief in attacks of demons furnishes them with a general theory to account for misfortunes, mysterious events, and especially all diseases of body or mind, so that the exorcists, who are usually priests or sorcerers, become in fact the recognized order of physicians (see article DEMONOLOGY). From among the numerous accounts of modes of exorcism among rude tribes may be instanced that among the Dakota Indians, where the medicine-man summoned to cure a sick person chants "hi-le-li-lah!" to the accompaniment of a gourd rattle, and sucks at the part affected till the possessing spirit is supposed to come out and take flight, when men in waiting at the tent-door fire guns at it (Schoolcraft, *Indian Tribes of North America*, part i. p. 250, part ii. p. 199); and that of the Zulus, among whom the ghosts of the dead who enter men's bodies and cause disease are got rid of by the sacrifice of cattle, with expostulations, such as, "I say, cease; leave off making me ill" (Callaway, *Religious System of the Amazulu*, p. 157). In the most ancient known civilizations we find records of exorcism. An Egyptian tablet records the possession of a princess of the land of Bakhten by a demon, and the exorcism of this spirit by the god Khonsu, who was sent thither in his ark and cured her at once, the spirit saying, "Thou hast come in peace, great god, driver away of possessors. I am thy slave, I will go to the place whence I came" (Birch, in *Records of the Past*, vol. iv. p. 53). Among the formulas in ancient Babylonian exorcism are such as these:—"May the noxious spirit of the neck, the noxious wind, from the man himself and the clothing of the body, be driven forth!" "From the burning spirit of the entrails, which devours the man, may the king of heaven preserve!" (Sayce, in *Records of the Past*, vol. i. p. 131.) In Greece men of no less distinction than Epicurus and Æschines were the sons of women who lived by the exorcist's art; and both were bitterly reproached, the one by the Stoics, and the other by Demosthenes (*De Cor.*), for having assisted their parents in these practices. This power was in some instances considered as a divine gift; in others it was thought to be acquired by investigations into the nature of demons and the qualities of natural productions, as herbs, stones, etc., and by the use of certain forms of adjurations and ceremonies. The power of expelling demons Josephus places among the endowments of Solomon, and relates that he left behind him the manner of using exorcisms by which they drive away demons. (For the pretended fragments of these books see Fabricius, *Cod. Pseud. Vet. Test.*, p. 1054.) He relates that he had seen a man named Eleazar releasing people that were demoniacal, in the presence of Vespasian, his sons, captains, and soldiers, by means of a certain root set in a ring, on the application of which to the nose of the patient, the devil was expelled through his nostrils. (See *Antiq.* viii. 2, ⸹ 5; and *De Bell Jud.* vii. 6, ⸹ 3.) The profession of exorcist was not uncommon among the Jews; and the epithet applied to such persons (*περιερχομένων*; Vulg., *de circumeuntibus Judœis*) perhaps indicates that they were travelling mountebanks. The passages of the New Testament which refer to the exorcism of demons from epileptic, insane, and other diseased persons are too numerous and well known to require particular reference. The prominence of exorcism in the early ages of the Christian church appears from its frequent mention in the writings of the fathers, and by the 3d century there seems to have been an order of exorcists (see Bingham, *Antiquities of the Christian Church*). The ancient rite of exorcism in connection with baptism is still retained in the Roman ritual, and is also a form of service for the exorcising of possessed persons. The exorcist signs the possessed person with the figure of the cross, desires him to kneel, and sprinkles him with holy water; after which the exorcist asks the devil his name, and abjures him by the holy mysteries of the Christian religion not to afflict the person possessed any more. Then, laying his right hand on the demoniac's head, he repeats the form of exorcism as follows: "I exorcise thee, unclean spirit, in the name of Jesus Christ; tremble, O Satan, thou enemy of the faith, thou foe of mankind, who hast brought death into the world, who hast deprived men of life, and hast rebelled against justice, thou seducer of mankind, thou root of evil, thou source of avarice, discord, and envy." Houses and other places supposed to be haunted by unclean spirits are likewise to be exorcised with similar ceremonies.

EXPIATION OR ATONEMENT, DAY OF (יוֹם הַכִּפֻּרִים, *ἡμέρα ἐξιλασμοῦ*), called in the Mishna simply "the Day," the only fast enjoined by the Mosaic legislation, occurred annually on the tenth day of the 7th month (Tisri). The laws for its observance are given in Lev. xvi. 1–34, xxiii. 27–32, and Numb. xxix. 7–11. The high priest was to enter the Most Holy Place according to a minutely detailed ritual, and so "make an atonement for" (כִּפֶּר) the sanctuary, the tabernacle, the altar, the priests, and all the people. From the one evening to the other the people were enjoined, under the severest penalties, to "afflict their souls," and observe a "perfect sabbath."

EXPLOSIVES. It lies beyond the object of this article to attempt an estimate of the influence, direct or indirect, upon modern civilization of the introduction of explosive agents for the purposes of war. Some eminent authors have gone so far as to consider the invention of gunpowder as next in importance, in its ultimate effects, to those of printing and the application of steam power. However this may be, it is well to remember that explosive substances are now of immense utility in the arts of peace; indeed, it is not too much to say that without their aid many of the great engineering enterprises of the present day would either be impossible, or else have to be carried out at a vast additional expenditure of time and labor.

The germ of all the knowledge of explosive reaction we possess undoubtedly lay in the probably accidental discovery, many ages ago, of the deflagrating properties of the natural substance nitre or saltpetre (KNO_3), when in contact with incandescent charcoal. To trace the consequences of that discovery, very gradual as they have been, and intimately bound up with the progress of chemical and mechanical science, belongs rather to an article on gunpowder; but the fact may be briefly referred to in connection with the second great epoch in the history of explosive substances. By distilling nitre with oil of vitriol, the alchemists obtained a corrosive fluid which they called *aquafortis*, now known as nitric acid (HNO_3) which parts with its oxygen even more readily than saltpetre; so that if the strongest nitric acid be poured upon finely powdered charcoal, the latter takes fire at the ordinary temperature. Somewhat less than half a century back, it was discovered by some French chemists that upon treating various organic substances, such as starch, the sugars, cotton fabrics, and even paper, with concentrated nitric acid under proper precautions, the chemical constitution of the substances underwent a great change, and they became endowed with violently explosive properties, while remaining for the most part unaltered in external characteristics. To this discovery we owe a distinct class of explosive compounds, the most powerful for practical purposes as yet known; their general formation and properties will be noticed in due course.

We will now proceed to examine into those principles of constitution and action which are more or less common to all explosive substances.

Definitions.

As the term is often rather loosely employed, "explosion" may for our purpose be defined as the sudden or extremely rapid conversion of a solid or liquid body of small bulk into gas or vapor, occupying very many times the volume of the original substance, and, in addition, highly expanded by the heat generated during the transformation. This sudden or very rapid expansion of volume is attended by an exhibition of force, more or less violent according to the constitution of the original substance and the circumstances of explosion. Any substance capable of undergoing such a change upon the application of heat, or other disturbing cause, is called "explosive."

Constitution of explosives.

The explosive substances that are practically the most important essentially contain carbon, oxygen, and nitrogen, the last always existing in a state of feeble combination with the whole or part of the oxygen, and thus creating that condition of unstable chemical equilibrium which is necessary. When explosion takes place, the nitrogen parts with its oxygen to the carbon, for which it has a great affinity, forming carbonic acid (CO_2) and carbonic oxide (CO) gases, the combination being accompanied with great generation of heat, and the nitrogen gas is set free. In most explosives there is also hydrogen accompanying the carbon, and by its combustion producing an extremely high temperature; it combines with part of the oxygen to form water in the form of greatly expanded vapor. Other subordinate elements are often present; in gunpowder, for instance, the potassium binds the nitrogen and oxygen loosely together in the state of saltpetre, and there is sulphur, a second combustible, whose oxidation evolves greater heat than that of carbon. When chlorate of potash is present, the chlorine plays the part of the nitrogen, and is set free in the gaseous state. Two very unstable and practically useless explosive substances, the so-called chloride and iodide of nitrogen, contain neither carbon nor oxygen; but their great violence is equally caused by the feeble affinities of nitrogen for other elements, large volumes of gaseous matter being suddenly disengaged from a very small quantity of a liquid and solid body respectively.

Explosives may be conveniently divided into two distinct classes,—(1) explosive mixtures, and (2) explosive compounds.

Explosive mixtures.

The first class consists of those explosive substances which are merely intimate mechanical mixtures of certain ingredients, and which can be again separated more or less completely by mechanical means, not involving chemical action. These ingredients do not, as a rule, possess explosive properties in their separate condition. There are, however, explosives which might almost be classed in both categories; for example, *picric powder* is composed of ammonium picrate and saltpetre, the former of which contains an explosive molecule, but is mixed with the latter to supply additional oxygen, and thus increase the force.

If a substance that will burn freely in air, combining gradually with the oxygen of the atmosphere, be ignited in pure oxygen gas, the combustion will be much more rapid, and the amount of heat generated greater, at the ordinary atmospheric pressure. If it be possible to burn the substance in a very condensed atmosphere of oxygen we can readily imagine the combustion being very greatly accelerated, and therefore increased in violence; this is what is ordinarily effected by an explosive "mixture." A combustible body and a supporter of combustion are brought into extremely close contact with one another, by means of intimate mechanical mixture; also, the supporter of combustion, or oxidizing agent, is present in a very concentrated form, constituting what may be termed a magazine of condensed oxygen, solid or liquid. In the case of the explosion of a definite chemical compound, the change may be considered as the resolution of a complex body into simpler forms; this is not, however, always the case when a mechanical mixture is concerned; gunpowder, for example, may be said to contain two elementary substances, carbon and sulphur, not in chemical union.

The chief explosive mixtures may be subdivided into "nitrate mixtures," and "chlorate mixtures."

Nitrate mixtures.

In the nitrates, the oxygen is held in combination with sufficient force to need a powerful disturbing cause to separate it, so that mixtures made from nitrates do not explode very readily, and their action is comparatively gradual; they are not sensitive to friction or percussion, and hence are tolerably safe. Any of the nitrates will form explosive mixtures with combustible substances, but nitrate of potash (KNO_3) is the only one practically employed. The nitrate of soda, called "cubical" or Chili saltpetre, has been used, but absorbs moisture from the air so readily as to give very inferior results. Gunpowder may be taken as the representative of the nitrate explosive mixtures. Picric powder, above referred to, has been proposed by Abel for use as a bursting charge for shells, as being more powerful than a corresponding charge of gunpowder, equally safe as regards friction or percussion, and less hygroscopic; it consists of two parts ammonium picrate, and three parts saltpetre, incorporated, pressed, and finished very much as ordinary gunpowder.

Chlorate mixtures.

The chlorates part with their oxygen far more readily than the nitrates, the strong affinities of chlorine for the metals coming into play, and consequently chlorate mixtures are very sensitive to friction and percussion, and explode with great violence; chlorate of potash, ($KClO_3$) is the only one used. Very many chlorate mixtures have been made, some of which are employed in fireworks. "White gunpowder" is a mixture of two parts chlorate of potash, one of yellow prussiate of potash, and one of sugar; it is exploded very easily by friction or percussion. The most important chlorate mixtures are those used for igniting other explosives, such as the composition for friction tubes for firing cannon, percussion cap composition, and percussion fuses for bursting shells on impact; it is sometimes mixed with sulphur, as a combustible, and sometimes with black sulphide of antimony, which gives a longer flame.

Explosive compounds.

In an explosive "compound," the elements are all in chemical combination, presenting a definite explosive "molecule," which contains so to speak, both the combustible and the supporter of combustion, in the closest possible union; we can therefore understand its action being much more sudden and violent than that of the most intimate mechanical mixture.

Nitro-substitution products.

The chief explosive compounds are formed from some organic substance containing carbon, hydrogen, and oxygen, by introducing into it, through the action of concentrated nitric acid, a certain portion of nitric peroxide (NO_2), in substitution for an equivalent amount of hydrogen. A new compound, differing outwardly very little, if at all, from the original substance, is thus formed, but in a very unstable state of chemical equilibrium, because of the feeble union of the nitrogen and oxygen in the NO_2 molecule. A slight disturbing cause brings into play the stronger affinity of the carbon and hydrogen for the large store of oxygen contained in the new compound. Gun-cotton and nitro-glycerin are the leading members of this group, being produced in a precisely similar manner, by the substitution of three molecules of NO_2 for three atoms of hydrogen (H). As those explosives will be elsewhere described in detail, we give the formation, as a representative member of the group, of nitro-phenol, or picric acid, by treating phenol, or carbolic acid, with a mixture of nitric and sulphuric acids, the latter being required to absorb the water and preserve the full strength of the nitric acid:—

Picric acid.

$$\underset{\text{Carbolic acid.}}{C_6H_6O} + \underset{\text{Nitric acid.}}{3HNO_3} = \underset{\text{Picric acid.}}{C_6H_3(NO_2)_3O} + \underset{\text{Water.}}{3H_2O}.$$

The formula of the product may be empirically written $C_6H_3N_3O_7$; it is, like gun-cotton and nitro-glycerin, a *tri-nitro* substitution product. Only the picrates, or salts of picric acid formed with potassium or ammonium, are used in practice, as possessing more force than the uncombined acid. From starch can be obtained, in a strictly analogous manner, an explosive called *xyloidine*, which is a *bi-nitro* product, two molecules of nitric peroxide being substituted for two atoms of hydrogen. In the case of *nitro-mannite*, an explosive made from mannite, one of the sugars, as many as six molecules of the NO_2 are inserted. The number of nitro-substitution products is very great, many of them being more or less violently explosive.

Fulminates.

The fulminates are among the most violent of all explosive compounds, their chemical stability being very small. Sudden in action, their effect is great locally; thus they are well adapted to the purpose, for which alone they are practically used, of igniting, or upsetting the equilibrium of, other explosives.

Fulminate of mercury is produced by adding alcohol (C_2H_6O), under careful precautions, to a solution of mercury in nitric acid; a gray crystalline precipitate is obtained, very heavy (sp. gr. 4·4), and so sensitive to friction or percussion that it is kept in the wet state. The results of analysis show one atom of mercury, and two each of carbon, nitrogen, and oxygen, so that the formula may be empirically written $HgC_2N_2O_2$, or perhaps more correctly $HgO.C_2N_2O$; the chemical factor C_2N_2O is called *fulminic acid*, but has never been produced separately. Opinions differ as to the precise "rational" formulæ of the fulminates, some chemists considering their process of formation to be similar to that of the nitro-substitution products. It will be observed that two atoms of nitrogen take the place of hydrogen, being the ratio of combining proportions of those elements. The products of combustion are carbonic oxide, nitrogen, and metallic mercury, and the violence of action is due to the sudden evolution of a volume of gas and vapor very large in comparison with that of the substance its density being so great. This fulminate enters into the composition used for percussion caps and electric fuzes; its practical value has of late years been immensely increased by the discovery of its power, even in very small quantities, to produce the almost instantaneous decomposition of several explosive substances.

Fulminate of silver is prepared in a similar manner, but, being far more sensitive, is of little practical value; it is employed, in very minute quantities, in making such toys as detonating crackers.

The difficulties in the way of estimating, with any accuracy, the *force* of explosive substances are very great, especially as no definite standard of comparison can be laid down. However, by means of theoretical considerations, combined with the results of actual experiment, a tolerably fair approximation may be arrived at.

Maximum tension in closed vessel.

When an explosive substance is exploded in a closed vessel sufficiently strong to resist rupture, the tension attains its maximum value in an extremely short space of time, and gradually decreases from the heat being conducted away by the metal envelope, and dispersed by radiation. It has, however, been demonstrated that, at the moment of maximum tension, the loss of pressure due to the communication of heat to the vessel, if the latter be filled with the explosive, is less than one per cent. The products of combustion, after cooling down, can easily be determined by analysis, and are then either (*a*) wholly gaseous, as for chloride or iodide of nitrogen; (*b*) gaseous and liquid, in the case of gun-cotton and nitro-glycerin; or (*c*) gaseous and solid, as with gunpowder. It is certain that, at the moment of explosion, the products of the more violent explosive compounds are wholly in a state of gas or vapor, but we should arrive at incorrect results by making the same assumption in the case of a mechanical mixture like gunpowder. The experiments of Nobel and Abel on "Fired Gunpowder" (*Phil. Trans. Roy. Soc.*, 1874), which are the most complete ever undertaken, show that the ultimately solid residue is, at the moment of explosion, in a liquid state, and most probably in a very finely divided condition; moreover, that, at that instant, it occupies a space the ratio of which is about ·6 that of the original volume, supposing the substance to fill the vessel in which it is exploded.

Provided the laws concerned can be supposed to hold good at such high temperatures, we may assume for the gaseous products of combustion the well-known equation of the elasticity and dilatibility of permanent gases—

$$pv = Rt, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where R is a constant, and t reckoned from absolute zero (−273° C.). For the sake of convenience, we will consider that a unit of weight of the explosive substance occupies a unit of volume, and, if P be maximum tension developed by the explosion, we have

$$\mathrm{P}(1-\rho) = \mathrm{RT}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where T is the temperature of explosion, and ρ the ratio of the volume of the non-gaseous products, taken as constant; we have also the relation

$$p_0(1-\rho) = \mathrm{R}.273, \quad . \quad . \quad . \quad . \quad . \quad (3)$$

when the vessel is cooled down to 0° C.; therefore, eliminating R between (2) and (3), we get

$$\mathrm{P} = \frac{p_0\mathrm{T}}{273}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

But permanent gases under the pressure p_0 in atmospheres, at a volume $(1-\rho)$, will occupy a space $p_0\,(1-\rho)$, if allowed to expand to the normal pressure of 760 mm.; calling this expanded volume V,

$$\mathrm{P} = \frac{\mathrm{VT}}{273\;1-\rho)}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5).$$

The large amount of aqueous vapor produced by the explosion of some compounds must be added to the value of V, its volume being calculated on the supposition that it can remain uncondensed at the temperature of 0° C.

We have no certain means of directly estimating the temperature of explosion, but if it be assumed, as is usually done, to be the temperature the total products of combustion would attain to if the whole amount of heat generated by the explosion were applied to raise them, under constant volume, from absolute zero, we have the relation

$$\mathrm{H} = \mathrm{T}c_v,$$

in which H represents the number of units of heat generated, and c the specific heat under constant volume of the united products, gaseous or otherwise. The quantity of heat can be obtained by experiment, and this, divided by the specific heat, will give the temperature. The chief sources of error lie in the assumption that the specific heat remains constant throughout the great range of temperature in question, and in the additional quantities of heat disengaged by secondary reactions. The value of T thus found probably will therefore be higher than the real temperature.

Explosive force.

Having regard to the above reasoning, it may be *generally* concluded that the amount of force exerted by an explosive substance depends upon —(1) the *volume of gas or vapor* produced by the transformation, compared with that of the original substance; and (2) the *temperature of explosion*, which determines the extent to which the gases are expanded, or their tension increased; or, in other words, the explosive force is *directly* proportional to the heat of combustion, and the volume of gas and vapor calculated at 0° C. and 7·60 mm. pressure, and *inversely* proportional to the specific heat of the mixed products.

It has been supposed by Berthelot and others that the volume of gas produced may possibly be still further increased by the partial or total "dissociation" of the compound gases, at the high temperatures concerned; for example, that the carbonic acid (CO_2) may be decomposed into carbonic oxide (CO) and oxygen, or the aqueous vapor into oxygen and hydrogen. However, Nobel and Abel demonstrate that, in the former instance, the loss of temperature, consequent upon the absorption of heat by the decomposition, would more than compensate for the increase of volume by dissociation. It must also be remembered that, if the temperature be extremely high, so also is the pressure under which dissociation must take place. We may therefore consider that it has no sensible influence upon the explosive force.

Explosive effect.

It is most important to distinguish between explosive force and explosive effect, the latter in great measure depending upon the rapidity with which the metamorphosis takes place, while the same amount of force may be exerted suddenly or gradually. We may, therefore, consider that the explosive effect varies *directly* as the volume of gas produced and the temperature of explosion, and *inversely* as the time required for the transformation. But the time, and to a certain extent, the products and temperature, will vary with—(*a*.) the physical state of the explosive substance; (*b*.) the external conditions under which it is fired; (*c*.) the mode of firing or exploding.

Physical state of explosives.

The physical or mechanical state of the explosive substance has a most important bearing upon the effect obtained from it. To prove this, it is only necessary to point to the very different results given by gunpowders made with the same proportions of the three ingredients, but varying in density, and in shape and size of grains or pieces. Gun-cotton is even more affected by variations in mechanical condition. In the form of loose wool, it burns so rapidly that gunpowder in contact with it is not inflamed; plaited or twisted tightly, its rate of combustion in air is greatly modified. This is due to the fact that the inflammable carbonic oxide, which is evolved by the decomposition from the want of sufficient stored-up oxygen to oxidize completely all the carbon of the gun-cotton, cannot penetrate between the fibres and accelerate the combustion, but burns with a bright flame away from the surface of the twisted cotton; when the yarn is yet more compressed by any means, the temperature is not kept up to the height necessary for the combustion of the carbonic oxide, so that it escapes unconsumed, abstracting heat, and yet more retarding the rate of burning. For the same reason, pulped and compressed gun-cotton burns comparatively slowly in air, even when dry; in the wet state, it merely smoulders away, as the portions in contact with the fire successively become dried. Yet this same wet compressed gun-cotton can be so used as to constitute one of the most powerful explosives known.

External conditions of explosion.

It is well known that gunpowder behaves differently when fired in the open air and under strong confinement; not only the rate of burning, but even, to a certain extent, the products of combustion are altered. We have discussed the effect of tightly plaiting or compressing gun-cotton; but, when confined in a strong envelope, the whole of the inflamed gas, being unable to escape outwards, is forced into the interstices under immense pressure, and the decomposition greatly accelerated. The amount of confinement or restraint needed by any explosive depends, however, upon the nature of the substance and the mode of exploding it, becoming very much less as the transformation is more rapid, until it may be said to reach the vanishing-point. For example, the very violent explosive chloride of nitrogen is usually surrounded, when exploded, with a thin film of water; Abel states that if this film, not exceeding $\frac{1}{1000}$ inch in thickness, be removed, the explosive effect is much lessened. Nitro-glycerin, again, when detonated by a fulminate, is sufficiently confined by the surrounding atmosphere. By the same means, gun-cotton may be exploded unconfined, if compressed, the mechanical cohesion affording sufficient restraint. In the case of wet compressed gun-cotton, which can be detonated with even fuller effect than dry, the mechanical resistance is greater, the air-spaces being filled with incompressible fluid.

Mode of exploding.

The manner in which the explosion is brought about has a most important bearing upon the effect produced. This may be done by the direct application of an ignited or heated body, by the use of an electric current to heat a fine platinum wire, or by means of percussion, concussion, or friction, converting mechanical energy into heat. A small quantity of a subsidiary explosive, such as a composition sensitive to friction or percussion, is often employed, for the sake of convenience, to ignite the main charge, the combustion spreading through the mass with more or less rapidity, according to the nature of the substance.

Detonation.

Although subsidiary or initiatory explosives were at first used merely to generate sufficient heat to ignite the charge, and are often still so employed, they have of late years received an application of far wider importance. Mr. Alfred Nobel, a Swedish engineer, while endeavoring to employ nitro-glycerin for practical purposes, found considerable difficulty in exploding it with certainty; he at length, in 1864, by using a large percussion cap, charged with fulminate of mercury, obtained an explosion of great violence. This result led to the discovery that many explosive substances, when exploded by means of a small quantity of a suitable initiatory explosive, produce an effect far exceeding anything that can be attributed to the ordinary combustion, however rapid, of the body in question; in fact, the whole mass of the explosive is converted into gas with such suddenness that it may, practically, be considered instantaneous; this sudden transformation is termed "detonation." Of the substances capable of producing such action, fulminate of mercury is the most important.

Two orders of explosives.

Some explosives appear always to detonate, in whatever manner they may be exploded, such as chloride and iodide of nitrogen; the explosive effect is therefore much greater than that of a slower explosive substance, although their explosive force may be less. Again, other substances, such as gun-cotton and nitro-glycerin, are detonated or not according to the mode of explosion. Indeed, Abel has proved that most explosives, including gunpowder, can be detonated, provided the proper initiatory charge be employed. Roux and Sarrau (*Comptes Rendus*, 1874) have divided explosions into two classes or orders,—"detonations" or explosions of the first order, and "simple explosions" of the second order. They made a series of experiments with the object of determining the comparative values of various explosive substances, detonated, and exploded in the ordinary manner; the method employed was to ascertain the quantity of each just sufficient to produce rupture in small spherical shells of equal strength. The following table gives the comparative results for the three most important explosive substances —

	Explosive Effect.	
	Second Order.	First Order.
Gunpowder..................	1·00	4·34
Gun-cotton or nitro-cellulose......	3·00	6·46
Nitro-glycerin.................	4·80	10·13

These experiments, although valuable, cannot be considered as affording a precise method of comparison; the results would be affected, *inter alia*, by the impossibility of ensuring that the shells were all of the same strength, a point of great importance, considering the very small weights of each explosive used; also the rate of combustion, and therefore the explosive effect, of gunpowder is materially affected by its mechanical condition, so that different powders would give a varying standard of comparison. However, they afford fair evidence that, when detonated, gun-cotton has about six times, and pure nitro-glycerin about ten times the local explosive effect of gunpowder simply ignited in the ordinary manner; nitro-glycerin is usually employed in the form of "dynamite," mixed with some inert absorbent substance, so that its power is proportionately reduced.

Theory of detonation.

The rationale of detonation is not yet understood. If the transformation were due merely to the mechanical energy of the particles of gas, liberated from the initiatory charge at a tremendous velocity, being converted into heat by impact against the mass of the explosive substance, then it would follow that the most powerful explosive would be the best detonating agent; this is, however, by no means the case, for a few grains of fulminate of mercury in a metal tube will detonate gun-cotton, whereas nitro-glycerin, although possessed of more explosive force, will not do so unless used in large quantities. The fact of its being possible to detonate wet gun-cotton is also a proof that the action cannot be due to heat alone. It would rather seem to be what Professor Bloxam terms "sympathetic" explosion; the experiments of Abel, as well as those of Champion and Pellet in France, appear to indicate a vibratory action of the detonating agent upon the ultimate particles of the substance to be exploded. An explosive molecule is most unstable, certain very delicately balanced forces preserving the chemical and physical equilibrium of the compound. If these forces be rapidly overthrown in succession, we have explosion; but when, by a blow of a certain kind, they are instantaneously destroyed, the result is detonation. Just as a glass globe may withstand a strong blow, but be shattered by the vibration of a particular note, so it is considered by some authorities that, in the instance cited, the fulminate of mercury communicates a vibration to which the gun-cotton molecule is sensitive, and which overthrows its equilibrium; it is not sensitive to the vibrations caused by the nitro-glycerin, which only tears and scatters it mechanically. Although the action of detonation has been spoken of as instantaneous, and may practically be so considered, yet a certain infinitesimal duration of time is required for the metamorphosis; different substances possess, doubtless, different rates of detonation, for we can scarcely conceive of a mechanical mixture, such as gunpowder, being so sensitive to the action of the detonating impulse as a definite chemical compound, and the rate even varies slightly, for the same explosive, with its physical state. It has been shown, by means of Captain A. Nobel's chronoscope, that compressed gun-cotton, when dry, is detonated at a velocity of from 17,000 to 18,000 feet a second, or about 200 miles a minute; by using a small primer of dry gun-cotton, the same substance in the wet state may be detonated at the increased rate of from 18,000 to 21,000 feet a second, or about 240 miles a minute.

The following results are taken from experiments on detonation and its applications, carried out by F. A. Abel, C.B., F.R.S.:—

I. *Illustrating some of the conditions which promote the detonation of an explosive substance—(a) Quality of the initial detonation; (b) Resistance to mechanical dispersion offered by the mass of the substance to be detonated.*

1. A fuze containing rather more than 1 oz. gunpowder, strongly confined, exploded in contact with a mass of compressed gun-cotton, only inflames it, although the explosion of the fuze is apparently a sharp one.
2. Forty-five grains of fulminate of mercury, exploded unconfined on the surface of a piece of compressed gun-cotton, only inflames or disperses it.
3. A fuze containing 9 grains fulminate of mercury, strongly confined, exploded in contact with compressed gun-cotton, or dynamite, detonates it with certainty.
4. An equal quantity of fulminate, similarly confined, does not detonate uncompressed gun-cotton in which it is imbedded, but merely disperses and inflames it.
5. 150 grains compressed gun-cotton, detonated in proximity to dynamite, detonates the latter.
6. 3 oz. of dynamite, and very much larger quantities, detonated in contact with compressed gun-cotton, only disperses it.

II. *Transmission of Detonation.*

7. Detonation being established at one extremity of a continuous row of distinct masses of compressed gun-cotton, or dynamite, travels the whole length thereof. Stretching insulating wires across the row of discs, at intervals of six feet, their rupture by the detonation gives spark-records on the cylinder of Nobel's chronoscope by means of which the rate of transmission can be calculated.

8. A row of gun-cotton discs, of any length, placed 0·5 inch apart, can all be detonated from one end.

9. Discs of compressed gun-cotton, weighing about 8 oz. each, being placed 6 inches apart, the detonation of the central disc only blows away or breaks up the neighboring masses.

10. About 2 oz. compressed gun-cotton being inserted into one extremity of a wrought-iron tube 5 feet long, its detonation is transmitted to a disc of compressed gun-cotton inserted into the other extremity of the tube.

III. *Applications of Detonation.*

11 A wrought-iron rail can be destroyed by detonating 8 oz. of compressed gun-cotton placed unconfined upon the rail.

12. A piece of wet gun-cotton, quite uninflammable, removed from a fire and detonated upon a block of granite, using a small primer of dry gun-cotton, shatters the block.

13. A stockade can be destroyed by means of a flat charge built up of wet gun-cotton slabs,—detonation being established by means of a small portion of the charge in a dry state.

14. A submerged charge of wet gun-cotton, open on all sides to the water, and merely confined around the dry initiative charge, or primer, by means of a net, can be detonated.

Relative force of explosives.

Many attempts have been made, especially by foreign chemists and physicists, to arrive at an exact determination of the comparative force of explosive substances. The means adopted may be summed up under the two headings of (1) experiment alone, and (2) calculation and experiment combined. In the first category may be placed the experiments of Roux and Sarrau, already noticed. By the second method, Berthelot (*Force de la Poudre et Matières Explosives*, 1872) calculates the volume of gases which would be produced, and having ascertained the quantity of heat generated by the explosion, considers that their product affords a term of comparison according fairly well with the results of experiment. Sarrau (*Effets de la poudre et des substances explosives*, 1874), from a train of reasoning somewhat similar to that here followed, arrives at the conclusion that the explosive force is nearly proportional to the product of the heat of combustion by the weight of permanent gases produced; he obtains both these data by experiments carried out at the Dépôt central des Manufactures de l'État. The following table shows the results of the two methods:—

Explosive Substance.	Relative Force.	
	Sarrau.	Berthelot.
Gunpowder	1·00	1·00
Gun-cotton	3·06	3·42
Nitro-glycerin	4·55	6·80
Picrate of potash	1·98	2·44
Picrate of potash and saltpetre.	1·49	2·07
Picrate and chlorate of potash	1·82	3·46
Chloride of nitrogen	1·08	0·85

The plan pursued by Sarrau appears the more reliable of the two, in that he obtains by experiment the quantity of permanent gases evolved; the relative proportions he gives agree fairly well with those experimentally determined by him, in conjunction with Roux, for simple explosion. With reference to Berthelot's figures, it is a well-known fact that nitro-glycerin, when not detonated, is very uncertain in its action, so that in all probability it would never give its full theoretic force; Sarrau seems nearer its correct value. On the other hand, chlorine gas, liberated by the explosion of chlorate of potash and chloride of nitrogen, is very heavy, so that considerable variation may arise from estimating it by weight instead of volume. The mean of the results given by five descriptions of gunpowder was adopted by Sarrau as his standard, and he estimates the pressure at about 5290 atmospheres. Nobel and Abel have proved these figures to be considerably too low; and we shall, in all probability, be not far wrong if we multiply each of the ratios given in Sarrau's table by 6000, in order roughly to show the pressure, in atmospheres, of equal weights of each of the substances in question exploded in about its own volume, but not detonated.

Products of combustion allowed to expand.

We have considered the tension developed in a close vessel of constant volume. Let us now investigate the case of the products of combustion being allowed to expand in a vessel impervious to heat, it having been conclusively proved that with large charges the loss of heat by communication to the metal of a gun is relatively very small, and may practically be neglected. If V, P, and T be respectively the initial volume occupied by the substance, the maximum pressure, and the temperature of explosion, we shall deduce expressions for the pressure and temperature corresponding to any volume v, and the work done by the expansion of the permanent gases in the space $v-\mathrm{V}$. It will simplify the calculation if we suppose that the gravimetric density of the substance is unity, that it fills the volume in which it is exploded, and that the charge is burnt before it commences to do work, either upon a projectile or otherwise; even with gunpowder the correction due to this last assumption is not great, and the action of the more violent explosives may practically be considered instantaneous, especially when detonated. It has already been stated that, with most explosives, there is an ultimately solid or liquid residue, the products not being wholly gaseous; with gunpowder this residue is very considerable.

As before, let ρ be the ratio of the volume of the non-gaseous products at the instant of explosion: then the original volume of gas and vapor will be $\mathrm{V}(1-\rho)$, and the expanded volume $v-\rho\mathrm{V}$; for the sake of brevity these corrections will be made at the end of the calculations. As already stated, for gunpowder the value of ρ is about ·6; it is relatively inconsiderable for the more violent explosive compounds.

Starting with the fundamental relation for permanent gases,

$$pv=\mathrm{R}t\,, \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

if we suppose the pressure to remain constant while the volume varies by an infinitesimal amount dv, the temperature will undergo a corresponding variation $\frac{pdv}{\mathrm{R}}$, and the gases gain or lose an amount of heat $\frac{c_p.pdv}{\mathrm{R}}$, c_p being the specific heat for constant pressure; similarly, if the volume be supposed to remain constant, while the pressure varies by dp, we have a gain or loss of heat $\frac{c_v.vdp}{\mathrm{R}}$, c_v being the specific heat for constant volume; consequently, when both pressure and volume vary simultaneously, the gain or loss of heat is

$$\frac{1}{\mathrm{R}}(c_p.pdv+c_v.vdp)=dh\,; \quad . \quad . \quad . \quad . \quad (2)$$

and differentiating (1),

$$pdv+vdp=\mathrm{R}dt\,. \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Eliminating vdp between these equations, we get

$$\frac{c_p-c_v}{\mathrm{R}}\,.\,pdv+c_v\,.\,dt=dh\,. \quad . \quad . \quad . \quad (4)$$

Again, if c' be the specific heat of the solid residue, assumed to be constant, and σ the ratio of its weight to that of the gas and vapor, it is evident that the residue will part with an amount of heat, $\sigma c'.dt$, during an instant of the expansion while the temperature is lowered by an amount dt; but, by our hypothesis, the heat given off by the residue is acquired by the gases; therefore,

$$dh=-\sigma c'.dt\,; \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

and (4) becomes, for the expansion from V to v,

$$-(c_v+\sigma c')\int_{\mathrm{T}}^{t}dt=\frac{c_p-c_v}{\mathrm{R}}\int_{\mathrm{V}}^{v}pdv\,. \quad . \quad . \quad (6)$$

Substituting for p its value derived from (1), dividing both sides by t, and integrating, we have

$$\log_\epsilon\left(\frac{t}{\mathrm{T}}\right)^{c_v+\sigma c'}=\log_\epsilon\left(\frac{\mathrm{V}}{v}\right)^{c_p-c_v}, \quad . \quad . \quad . \quad (7)$$

whence

$$t=\mathrm{T}\,.\left(\frac{\mathrm{V}}{v}\right)^{\frac{c_p-c_v}{c_v+\sigma c'}}, \quad . \quad . \quad . \quad . \quad . \quad (8)$$

making the correction for the volume of the solid or liquid residue

$$t=\mathrm{T}\,.\left\{\frac{\mathrm{V}(1-\rho)}{v-\rho\mathrm{V}}\right\}^{\frac{c_p-c_v}{c_v+\sigma c'}} \quad . \quad . \quad . \quad (9)$$

In a precisely similar manner, or more briefly by remembering that $PV = RT$, we find

$$p = P\left\{\frac{V(1-\rho)}{v-\sigma V}\right\}^{\frac{cp + \sigma c'}{cv + \sigma c'}} \quad . \quad . \quad . \quad (10)$$

Work done by the expansion.

But the definite integral $\int_V^v pdv$, represents the work done by the expansion of the gas and vapor from the volume V to any volume v, and from equation (6),

$$\int_V^v pdv = -\frac{R(c_v + \sigma c')}{c_p - c_v}\int_T^t dt \quad . \quad . \quad . \quad (11)$$

Integrating, and remembering that $c_p - c_v = \frac{R}{J}$, where J is Joule's mechanical equivalent of heat, we get

$$W = J(c_v + \sigma c')\{T - t\}, \quad . \quad . \quad . \quad . \quad (12)$$

or the work done is directly proportional to the loss of temperature during the expansion.

Substituting the value above found for t, we have

$$W = JT(c_v + \sigma c')\left\{1 - \left(\frac{V(1-\rho)}{v-\rho V}\right)^{\frac{cp - cv}{cv + \sigma c'}}\right\} \quad (13)$$

but $T(c_v + \sigma c') = H$, the whole amount of heat generated by the explosion, so that we have the expression,

$$W = JH\left\{1 - \left(\frac{V\,(1-\rho)}{v-\rho V}\right)^{\frac{cp - cv}{cv + \sigma c'}}\right\}. \quad . \quad . \quad (14).$$

This expression for the work done is of considerable practical value in the case of gunpowder, or any explosive which can be used as a propelling agent with heavy guns. Knowing the length and diameter of the bore, we can calculate the total maximum work due to a given weight of charge in expanding to that volume. This maximum is of course not attained in practice, and it is therefore necessary to multiply it by a ratio, or factor, dependent on the nature of the gun and projectile, the powder used, mode of ignition, etc. However, by making use of the results of actual experiment, this "factor of effect," or percentage of work realized, can be determined with much accuracy. Its value is greatest for very large guns, being 93 per cent. for the 38-ton gun, and becoming as low as about 50 per cent. in the case of the little 7-pr. mountain gun of 150 lb. weight; the difference is chiefly due to the loss of heat by communication to the metal of the gun. (See Nobel and Abel on "Fired Gunpowder.")

Initial velocity.

We can approximate to the "muzzle velocity," or the velocity at which the projectile leaves the bore, by substituting the value of W, found for the particular gun, in the ordinary equation of work, $W = \frac{wV^2}{2g}$, where V is the velocity, and w the weight of the projectile; we thence obtain

$$V = \sqrt{\frac{2g}{w}.Wf.}$$

If W, the maximum work due to the expansion of the gaseous products in the volume of the bore, be multiplied by the factor of effect f, for the nature of gun and powder used, the result will be very nearly the mean observed velocity.

Graphical representation of work.

The mathematical expression for the work done by an explosive substance in expanding from V to v, or $\int_V^v pdv$, evidently denotes the area of a plane curve; the work may therefore be graphically represented by the area enclosed by a curve, having for its ordinates the pressures in foot-tons, or atmospheres, and for abscissæ the corresponding volumes or spaces occupied by the gases.

Total theoretic work.

If, in equation (14), we take the limits between V and infinity, we arrive at a very simple expression for the total theoretic work due to the indefinite expansion of a given weight of any explosive substance, v becoming indefinitely great compared to the original volume V, and we have

$$W = JH, \quad . \quad . \quad . \quad . \quad . \quad . \quad (15)$$

which may be called the "potential energy" of the explosive, being the product of the total quantity of heat generated by the explosion and the mechanical equivalent of heat. This conclusion, within the assumptions made, is in strict accordance with the principle of the mutual convertibility of energy and heat.

The following table shows the potential energy, in foot-tons, calculated from the heat of combustion for each explosive, determined by Roux and Sarrau, in the experiments already referred to; that for gunpowder is the mean given by five kinds.

Explosive Substance.	Potential Energy per lb. Foot-tons.
Gunpowder	480
Gun-cotton	716
Nitro-glycerin	1139
Picrate of potash	536
Picrate of potash and saltpetre	615
Picrate and chlorate of potash	781
Chloride of nitrogen	216

The above figures naturally direct our attention to the small amount of work stored up in even the most violent explosive substance, compared with the potential energy of 1 lb. of coal, which is about 4980 foot-tons. Nobel and Abel point out that this great difference is not alone due to the fact that the coal draws its oxygen from the air, but also because the explosive has to expend a considerable amount of work in converting its condensed magazine of oxygen into gas, before it can combine with the carbon; further, with reference to the economic value of the work done, that the oxygen used by the coal costs nothing, whereas much expense is incurred in condensing the oxygen into the explosive substance.

Practical value of an explosive.

The practical value of any explosive must depend greatly upon the object to be attained. It is essential to distinguish between explosive force and effect; the more sudden the action the more local will be the effect produced, and hence the very violent explosive substances are useless as propelling agents for heavy guns or small arms, since they would destroy the weapon before overcoming the inertia of the projectile. It is true that gun-cotton, prepared in various forms, and mixed with other substances to moderate its action, as well as a similar compound made from saw-dust, an inferior form of cellulose, are sometimes used with small arms; but, in addition to a want of uniformity in action, the strain caused by such substances would be far too great in the large charges needed for heavy guns. Again, there are cases, even in mining or blasting operations, for instance, when it is desired to displace large masses of earth or soft rock, in which a comparatively slow explosive, such as gunpowder, would give better results than gun-cotton or dynamite. However, speaking generally, gunpowder in some one of its forms is far the most valuable as a propelling agent, while, for destructive purposes, the last-named substances are much more effective, especially when detonated.

Law relating to explosives.

Law.—In 1860 an Act was passed "to amend the law concerning the making, keeping, and carriage of gunpowder and compositions of an explosive nature, and concerning the manufacture and use of fireworks" (23 and 24 Vict. c. 139), whereby previous Acts on the same subject were repealed, and minute and stringent regulations introduced. Gunpowder may only be manufactured in mills, lawfully used at the commencement of the Act, or duly licensed as in this Act provided; other explosive compositions require a license, and the precautionary rules as to quantity, distance from dwelling houses, etc., are set forth in minute detail. No person may sell fireworks without a license, or to persons apparently under 16 years of age; and throwing fireworks on the streets was made punishable by a penalty not exceeding £5. Other regulations deal with carriage by land and sea, search-warrants, inspections of mills, etc. Amending Acts were passed in 1861 and 1862.

In 1875 was passed the "Explosives Act" (38 Vict. c. 17), which repeals the former Acts, and deals with the whole subject in a more comprehensive manner. "Explosives" are thus defined:—(1) Gunpowder, nitro-glycerin, dynamite, gun-cotton, blasting powders, fulminate of mercury or of other metals, colored fires, and every other substance, whether similar to those above mentioned or not, used or manufactured with a view to produce a practical effect by explosion or a pyrotechnic effect, and including (2) fog-signals, fireworks, fuzes, rockets, percussion caps, detonators, cartridges, ammunition of all descriptions, and every adaptation or preparation of an explosive as above defined. Part i. deals with gunpowder; part ii. with nitro-glycerin and other explosives; part iii. with inspection, accidents, search, etc.; part iv. with various supplementary provisions. In addition to the license required for manufacturing gunpowder, it is provided that gunpowder shall not be kept in any place except (1) a licensed factory, (2) a licensed magazine or store, or (3) premises registered for keeping gunpowder. Private persons may keep gunpowder for their own use to the amount of thirty pounds. Rules for the proper keeping of gunpowder on such registered premises are prescribed. The Act contains 122 sections, and applies to Scotland and Ireland as well as England. It was based on the report of a Committee of the House of Commons. Public opinion had been greatly excited on the subject by the terrible explosion on the Regent's Canal in 1874.

Petroleum is governed by the Petroleum Act 1871—an annual Act, which has been included every year in the Expiring Acts Continuance Bill.

In 1877 the "Fisheries (Dynamite) Act" was passed, whereby any person who uses dynamite or other explosive substance to catch or destroy fish in a public fishery, shall be liable, on summary conviction, to a fine not exceeding £20, or imprisonment for a term of not more than two months.

Bibliography.—See, on the general subject, the following works:—Count de St. Robert, *Traité de Thermodynamique*, Turin, 1865; Berthelot, "Recherches de Thermochimie," *Annales de Physique et de Chimie*, tome vi.; Berthelot, *Sur la Force de la Poudre et les Matières Explosives*, 1872; Roux and Sarrau, "Experiments on Explosives," *Comptes Rendus*, tome lxxvii. 1874: Bunsen and Schiskoff's "Researches on Fired Gunpowder," *Poggendorff's Annalen*, vol. cii.; Sarrau, *Recherches théoriques sur les effets de la poudre et des substances explosives*, 1874; Nobel and Abel, *Researches on Explosives—Fired Gunpowder*, 1875; *Recent investigations and applications of explosive agents*, F. A. Abel, F.R.S., 1871; "Contributions to the history of explosive agents," F. A. Abel, F.R.S. (*Proc. Roy. Soc.*, No. 150, 1874); *Chemistry Inorganic and Organic*, C. L. Bloxam (articles on Gunpowder, Gun-cotton, etc.), London, 1875; "Vibratory motions produced by Detonants," Champion and Pellet (*Comptes Rendus*, vol. lxxv.); *Notes on certain Explosive Agents*, Walter N. Hill, S. B. Chemist, U. S. Torpedo Service, Boston, 1875. The Bibliography of explosives is chiefly contained in memoirs scattered throughout proceedings of various learned societies. (W. H. W.)

EXTRADITION. When a person who has committed an offence in one country escapes to another, what is the duty of the latter with regard to him? Should the country of refuge try him in its own courts according to its own laws, or deliver him up to the country whose laws he has broken? To the general question international law gives no certain answer. Some jurists, Grotius among them, incline to hold that a state is bound to give up fugitive criminals, but the majority appear to deny the obligation as a matter of right, and prefer to put it on the ground of comity. And the universal practice of nations is to surrender criminals only in consequence of some special treaty with the country which demands them.

There are two practical difficulties about extradition which have probably prevented the growth of any uniform rule on the subject. One is the variation in the definitions of crime adopted by different countries. The second is the possibility of the process of extradition being employed to get hold of a person who is wanted by his country, not really for a criminal, but for a political offence. In modern states, and more particularly in England, offences of a political character have always been carefully excluded from the operation of the law of extradition.

Extradition, as stated above, has for the most part been regulated by special treaties. A full list of the extradition treaties between the principal civilized countries will be found in Phillimore's *International Law*, vol. i. c. 21. Just before the passing of the Extradition Act of 1870, England had only two treaties subsisting—one with France, another with the United States. Both were confirmed by Acts of Parliament. The "Extradition Act 1870" enacts that "where an arrangement has been made with any foreign state, with respect to the surrender to such state of any fugitive criminals, Her Majesty may, by Order in Council, direct that this Act shall apply in the case of such foreign state," subject to any limitations, conditions, or restrictions that may be thought expedient. It is expressly provided—

1. That a fugitive criminal shall not be surrendered for a political offence, or if he prove that his surrender has in fact been required with a view of trying him for a political offence.
2. Provision must be made that a surrendered criminal shall not be tried for any but the extradition crime.
3. Criminals accused or convicted of offences in England shall not be surrendered in extradition until they are discharged.
4. There must be an interval of 15 days between the committal to prison and the surrender.

An Order in Council under the Act must be in conformity with its provisions, and must provide for the determination of the arrangement after not more than a year's notice.

When the Act applies, a fugitive criminal of a foreign state is liable to surrender. A requisition for that purpose must be addressed to a secretary of state by some person recognized as a diplomatic representative of the foreign state. The secretary of state, unless he thinks the offence is one of a political character, may inform a police magistrate of the requisition, and require him to issue his warrant for the apprehension of the criminal. The police magistrate, when the criminal is brought before him, shall receive any evidence tending to show that the offence is political, or is not an extradition crime. If the evidence is such as would justify a committal for trial in England, or would prove that the prisoner has been convicted, the magistrate commits him to prison, and after fifteen days' interval, or if a *habeas corpus* is issued after the decision of the court, the secretary of state may by his warrant deliver him over to the representatives of the foreign country. If the prisoner is not removed within two months he must be discharged. The Act applies, with certain modifications, to all British possessions.

"Fugitive criminal" means any person accused or convicted of an extradition crime committed within the jurisdiction of any foreign state, who is in, or is suspected of being in, any portion of Her Majesty's dominions. The following is a list of extradition crimes, to be construed according to the law existing in England:—

Murder and attempt and conspiring to murder; manslaughter; counterfeiting or altering money, and uttering; forgery, counterfeiting, and altering what is forged, etc.; embezzlement and larceny; obtaining money and goods by false pretences; bankruptcy crime; fraud by bailee, banker, agent, etc., rape; abduction; child-stealing; burglary and housebreaking; arson; robbery with violence; threats by letter or otherwise, with intent to extort; piracy by law of nations; sinking or destroying a vessel at sea, or attempting or conspiring to do so; assaults on board ship on the high seas, with intent to destroy life or to do grievous bodily harm; revolt or conspiracy to revolt by two or more persons on board a ship on the high seas against the authority of the master. The Extradition Act of 1873 adds the following:—Kidnapping and false imprisonment; perjury and subornation of perjury; and indictable offences, not previously named under the Larceny and other Criminal Acts of 1861 (24 and 25 Vict. c. 96, 97, 98, 99, 100, 101).

The countries with which England has entered into extradition treaties are the following:—Austria, 3d December, 1873; Belgium, 30th May, 1876; Brazil, 13th November, 1872; Denmark, 31st March, 1873; France, 13th February, 1843; Germany, 14th May, 1872; Hayti, 7th December, 1874; Honduras, 6th January, 1874; Italy, 5th February and 7th May, 1873; Netherlands, 10th June, 1874; Sweden and Norway, 26th June, 1873; Switzerland, 31st March, 1874; United States, 9th August, 1842 (Abdy's edition of Kent's *International Law*, Cambridge, 1878). The treaties with France and the United States, it will be noticed, are those which were in force before the English Extradition Acts. Difficulties have arisen between this country and the United States as to the effect of the Extradition Act on the subsisting treaty. In 1875 the English Government protested against the trial for a second offence of a criminal who had been surrendered to the United States. The United States Government maintained that the principle of the English Extradition Act (that the surrendered criminal shall not be tried for any offence committed prior to his surrender other than the extradition crime) did not apply to the treaty of 1842, that this treaty could not be newly construed at the will of one of the parties, and that the claim of the English Government made it impossible for the United States to ask or grant extradition under it. The English Government have in the mean time surrendered three fugitive criminals without insisting on their claim. A royal commission on the Extradition Acts is now sitting (1878).

See *A Treatise on the Law of Extradition*, by Edward Clark, barrister-at-law, 2d edition, London, 1874. (E. R.)

EXTREME UNCTION, one of the seven sacraments of the Romish Church, now to be administered only after those of penance and the Eucharist to persons who are supposed to be at the point of death. Among the Orientals oil has long been employed as a cure for various disorders, as well as for the purpose of promoting the general health of the body. According to the narrative of Mark, it was employed by the disciples of Jesus apparently for the purpose of effecting miraculous cures (Mark vi. 13). The apostle James also exhorts Christians to make use of it, accompanied with prayer, in the case of sick persons. "Is any sick among you, let him call for the elders of the church; and let them pray over him, anointing him with oil in the name of the Lord; and the prayer of faith shall save the sick, and the Lord shall raise him up; and if he have committed sins, they shall be forgiven him" (James v. 14, 15). Unction is not referred to by any of the fathers as a sacrament, but Origen, in his second homily on Lev. iv., implies that in his time it was conjoined with the imposition of hands in the restoration of the lapsed; and Irenæus (i. 21, 5) states that among some of the Gnostics it was common to anoint the dying with a mixture of oil or opobalsam and water, to render their souls invisible to their spiritual enemies in the other world, and proof against their machinations. There is evidence that among the Christians of the 4th century a superstitious efficacy was ascribed to the use of oil in cases of sickness, and instances are recorded in which the oil used in the lamps of the churches was stolen in order to be applied in sickness, or to ward off attacks of disease. The first proof of the use of the rite in the Roman Church is contained in a letter of Innocent I. to Decentius, bishop of Eugubium (Gubbio), in the year 416, in which he speaks of it as "a kind of sacrament;" but he adds that after the oil has been blessed by the bishop, it may be used, not merely by the bishops and priests, but by Christians generally. From the 8th century the rite is often mentioned in the acts of the councils, and has been the occasion of a considerable amount of discussion and difference of opinion, at least in regard to details. In 850 it was declared by the synod of Regiaticinum (Pavia) to be a sacrament by which sins were forgiven, and consequently bodily health restored, but its chief purpose was represented to be the restoration of the sick person. In the 12th century the question whether the rite could be repeated was raised, and began to be answered in the negative; and an attempt was made by some to obtain a decision that the person to whom it had been administered should not afterwards touch the earth with his bare feet, nor indulge in any of the pleasures of the flesh; and although these proposals were not carried, the general result of the discussions was to deepen the impression that it was a rite of unusual solemnity, to which recourse should not be had except in cases of great necessity. About this time the rite came to be known as *sacramentum exeuntium* or *extrema unctio*. By Peter the Lombard it was placed fifth in the list of the seven sacraments, and its spiritual significance was further developed by the scholastic theologians, especially by Thomas Aquinas. According to him, its principal end was the removal of the spiritual weakness resulting from the sins of the past life, and the healing of the body was only its secondary end; but among other theologians of his time discussions as to the purpose of the rite were the cause of considerable difference of opinion. It was, however, regarded by most as having only a relative necessity, its omission not entailing any positive spiritual evil. According to the decrees of the Council of Trent, it confers the pardon of any faults that may previously have been unexpiated, and it removes the remains of sin; it relieves and strengthens the soul, and enables it better to bear up under pain, and more successfully to withstand the assaults of the devil—bodily ease and health following so far as these are advantageous to the soul's welfare. As to its repetition the council contented itself with declaring that it might be repeated in cases of similar peril. According to the Romish catechism, two ends are obtained by its observance,—1st, the pardon of venial sins, it not possessing the highest efficacy in regard to mortal sins; 2d, the removal of the spiritual infirmity resulting from sin, and of all the other remains of sin. For the observance of the rite the Romish Church appeals to the authority of Christ, as implied in Mark vi. 13, and to the authority of the apostles, as implied in James v. 14, 15. The Council of Trent has decreed extreme unction to be a sacrament, and declares that "whosoever shall affirm that extreme unction is not truly and properly a sacrament, instituted by Christ our Lord, and published by the blessed apostle James, but only a ceremony received from the fathers, or a human invention, is to be accursed." And it denounces a similar anathema against all who "shall affirm that the sacred unction of the sick does not confer grace, nor forgive sin, nor relieve the sick, but that its power has ceased, as if the gift of healing existed only in past ages." The ceremony is performed in the following way. When a person's recovery is despaired of, his eyes, ears, nostrils, mouth, hands, feet, and reins are successively anointed with the sacred oil by the priest. At each anointing the priest says, "By this holy unction, and through His great mercy, Almighty God forgive thee whatever sins thou hast committed by sight" (or smell, hearing, touch, etc.). The oil used in extreme unction is supposed to represent the grace of God poured down into the soul, and conferring pardon and spiritual strength. It is blessed by the bishop on Maundy Thursday, and delivered to the parochial clergy to be used by them throughout the year. If any oil is left after the expiry of the year it is burned, and if the supply threatens to become exhausted, other oil may be added to that which has been consecrated, but only a small proportion of new oil is permitted. In the Greek church the rite is called 'Ευχέλαιον, or "Αγιον ἔλαιων. The oil is not consecrated by the bishop, but is taken out of the sanctuary lamps as required and blessed by seven priests, or, if that number cannot be gathered together, by not less than three. The rite is administered in diseases of all kinds; and such sick persons as are able are expected to visit the church, especially on Maundy Thursday, to experience its bodily and spiritual blessings. Only in extreme cases does the anointing take place in the sick chamber.

EYCK, VAN, the name of a family of painters in whose works the rise and mature development of art in western Flanders are represented. Though bred in the valley of the Meuse, they finally established their professional domicile in Ghent and in Bruges; and there, by skill and inventive genius, they changed the traditional habits of the earlier schools, remodelled the primitive forms of Flemish design, and introduced a complete revolution into the technical methods of execution familiar to their countrymen.

1. HUBERT VAN EYCK was the oldest and most remarkable of this race of artists. The date of his birth and the records of his progress are lost amidst the ruins of the earlier civilization of the valley of the Meuse. He was born about 1366, at Maeseyck, under the shelter or protection of a Benedictine convent, in which art and letters had been cultivated from the beginning of the 8th century. But after a long series of wars,—when the country became insecure, and the schools which had flourished in the towns decayed,—he wandered to Flanders, and there for the first time gained a name. As court painter to the hereditary prince of Burgundy, and as client to one of the richest of the Ghent patricians, Hubert is celebrated, Here, in middle age, between 1410 and 1420, he signalized himself as the inventor of a new method of painting. Here he lived in the pay of Philip of Charolais till 1421. Here he painted pictures for the corporation, whose chief magistrates honored him with a state visit in 1424. His principal master-piece, and the only picture that can be traced to his hand, the Worship of the Lamb, commissioned by Jodocus Vijdts, lord of Pamele, is the noblest creation of the Flemish school, a piece of which we possess all the parts dispersed from St. Bavon in Ghent to the galleries of Brussels and Berlin,—one upon which Hubert labored till he died, leaving it to be completed by his brother. Almost unique as an illustration of contemporary feeling for Christian art, this great composition can only be matched by the Fount of Salvation, in the museum of Madrid. It represents, on numerous panels, Christ on the judgment seat, with the Virgin and St. John the Baptist at His sides, hearing the songs of angels, and contemplated by Adam and Eve, and, beneath him, the Lamb shedding His blood in the presence of angels, apostles, prophets, martyrs, knights, and hermits. On the outer sides of the panels are the Virgin and the angel annunciate, the sibyls and prophets who foretold the coming of the Lord, and the donors in prayer at the feet of the Baptist and Evangelist. After this great work was finished it was placed, in 1432, on an altar in St. Bavon of Ghent, with an inscription on the framework describing Hubert as "*maior quo nemo repertus*," and setting forth, in colors, as imperishable as the picture itself, that Hubert

began and John afterwards brought it to perfection. John Van Eyck certainly wished to guard against an error which ill-informed posterity showed itself but too prone to foster, the error that he alone had composed and carried out an altarpiece executed jointly by Hubert and himself. His contemporaries may be credited with full knowledge of the truth in this respect, and the facts were equally well known to the duke of Burgundy or the chiefs of the corporation of Bruges, who visited the painter's house in state in 1432, and the members of the chamber of rhetoric at Ghent, who reproduced the Agnus Dei as a *tableau vivant* in 1456. Yet a later generation of Flemings forgot the claims of Hubert, and gave the honors that were his due to his brother John exclusively.

The solemn grandeur of church art in the 15th century never found, out of Italy, a nobler exponent than Hubert Van Eyck. His representation of Christ as the judge, between the Virgin and St. John, affords a fine display of realistic truth, combined with pure drawing and gorgeous color, and a happy union of earnestness and simplicity with the deepest religious feeling. In contrast with earlier productions of the Flemish school, it shows a singular depth of tone and great richness of detail. Finished with surprising skill, it is executed with the new oil medium, of which Hubert shared the invention with his brother, but of which no rival artists at the time possessed the secret,—a medium which consists of subtle mixtures of oil and varnish applied to the moistening of pigments after a fashion only kept secret for a time from guildsmen of neighboring cities, but unrevealed to the Italians till near the close of the 15th century. When Hubert died on the 18th September, 1426, he was buried in the chapel on the altar of which his masterpiece was placed. According to a tradition as old as the 16th century, his arm was preserved as a relic in a casket above the portal of St. Bavon of Ghent. During a life of much apparent activity and surprising successes, he taught the elements of his art to his brother John, who survived him.

2. JOHN VAN EYCK. The date of his birth is not more accurately known than that of his elder brother, but he was born much later than Hubert, who took charge of him and made him his "disciple." Under this tuition John learnt to draw and paint, and mastered the properties of colors from Pliny. Later on, Hubert admitted him into partnership, and both were made court painters to Philip of Charolais. After the breaking up of the prince's household in 1421, John became his own master, left the workshop of Hubert, and took an engagement as painter to John of Bavaria, at that time resident at the Hague as count of Holland. From the Hague he returned in 1424 to take service with Philip, now duke of Burgundy, at a salary of 100 livres per annum, and from that time till his death John Van Eyck remained the faithful servant of his prince, who never treated him otherwise than graciously. He was frequently employed in missions of trust; and following the fortunes of a chief who was always in the saddle, he appears for a time to have been in ceaseless motion, receiving extra pay for secret services at Leyden, drawing his salary at Bruges, yet settled in a fixed abode at Lille. In 1428 he joined the embassy sent by Philip the Good to Lisbon to beg the hand of Isabella of Portugal. His portrait of the bride fixed the duke's choice. After his return he settled finally at Bruges, where he married, and his wife bore him a daughter, known in after years as a nun in the convent of Maeseyck. At the christening of this child the duke was sponsor, and this was but one of many distinctions by which Philip the Good rewarded his painter's merits. Numerous altarpieces and portraits now give proof of Van Eyck's extensive practice. As finished works of art and models of conscientious labor they are all worthy of the name they bear, though not of equal excellence, none being better than those which were completed about 1432. Of an earlier period, a Consecration of Thomas à Becket has been preserved, and may now be seen at Chatsworth, bearing the date of 1421; no doubt this picture would give a fair representation of Van Eyck's talents at the moment when he started as an independent master, but that time and accidents of omission and commission have altered its state to such an extent that no conclusive opinion can be formed respecting it. The panels of the Worship of the Lamb were completed nine years later. They show that John Van Eyck was quite able to work in the spirit of his brother. He had not only the lines of Hubert's compositions to guide him, he had also those parts to look at and to study which Hubert had finished. He continued the work with almost as much vigor as his master. His own experience had been increased by travel, and he had seen the finest varieties of landscape in Portugal and the Spanish provinces. This enabled him to transfer to his pictures the charming scenery of lands more sunny than those of Flanders, and this he did with accuracy and not without poetic feeling. We may ascribe much of the success which attended his efforts to complete the altarpiece of Ghent to the cleverness with which he reproduced the varied aspect of changing scenery, reminiscent here of the orange groves of Cintra, there of the bluffs and crags of his native valley. In all these backgrounds, though we miss the scientific rules of perspective, with which the Van Eycks were not familiar, we find such delicate perceptions of gradations in tone, such atmosphere, yet such minuteness and perfection of finish, that our admiration never flags. Nor is the color less brilliant or the touch less firm than in Hubert's panels. John only differs from his brother in being less masculine and less sternly religious. He excels in two splendid likenesses of Jodocus Vijdts and his wife Catherine Burluuts. The same vigorous style and colored key of harmony characterizes the small Virgin and Child of 1432 at Ince, and the Madonna, probably of the same date, at the Louvre, executed for Rollin, chancellor of Burgundy. Contemporary with these, the male portraits in the National Gallery, and the Man with the Pinks, in the Berlin Museum (1432–4), show no relaxation of power; but later creations display no further progress, unless we accept as progress a more searching delicacy of finish, counterbalanced by an excessive softness of rounding in flesh contours. An unfaltering minuteness of hand and great tenderness of treatment may be found, combined with angularity of drapery, and some awkwardness of attitude, in a full-length portrait couple at the National Gallery (1434), in which a rare insight into the detail of animal nature is revealed in a study of a terrier dog. A Madonna with Saints, at Dresden, equally soft and minute, charms us by the mastery with which an architectural background is put in. The bold and energetic striving of earlier days, the strong bright tone, are not equalled by the soft blending and tender tints of the later ones. Sometimes a crude ruddiness in flesh strikes us as a growing defect, an instance of which is the picture in the museum of Bruges, in which Canon Van der Paelen is represented kneeling before the Virgin under the protection of St. George (1434). From first to last Van Eyck retains his ability in portrait. Fine specimens are the two male likenesses in the gallery of Vienna (1436), and a female, the master's wife, in the gallery of Bruges (1439). His death in 1440–41 at Bruges is authentically recorded. He was buried in St. Donat. Like many great artists he formed but few pupils. Hubert's disciple, Jodocus of Ghent, hardly does honor to his master's teaching, and only acquires importance after he has thrown off some of the peculiarities of Flemish teaching. Petrus Cristus, who was taught by John, remains immeasurably behind him in everything that relates to art. But if the personal influence of the Van Eycks was small, that of their works was immense, and it is not too much to say that their example, taken in conjunction with that of Van der Weyden, determined the current and practice of painting throughout the whole of Europe north of the Alps for nearly a century.

(J. A. C.)

EYE. The sense of vision is excited by the influence of light on the retina, the special terminal organ connected with the optic nerve. By excitation of the retina, a change is induced in the optic nerve fibres, and is conveyed by these to the brain, the result being a luminous perception, or what we call a sensation of light or color. If light were to act uniformly over the retina, there would be no image of the source of the light formed on that structure, and consequently there would be only a general consciousness of light, without reference to any particular object. One of the first conditions, therefore, of vision for useful purposes is the formation of an image on the retina. To effect this, just as in a photographic camera, refractive structures must be placed in front of the retina which will so bend luminous rays as to bring them to a focus on the retina, and thus produce an image. Throughout the animal kingdom, various arrangements are found for this purpose; but they may be all referred to three types, namely—(1) eye-specks or eye-dots, met with in Medusæ, Annelidæ, etc.; (2) the compound eye, as found in insects and crustaceans;

and (3) the simple eye, common to all vertebrates. The *eye-specks* may be regarded simply as expansions of optic nerve filaments, covered by a transparent membrane, but having no refractive media, so that the creature would have the consciousness of light only, or a simple luminous impression, by which it might distinguish light from darkness. The *compound eye* (an account of which, as met with in the common lobster, will be found under CRUSTACEA, vol. vi. p. 563) consists essentially of a series of transparent cone-like bodies, arranged in a radiate manner against the inner surface of the cornea, with which their bases are united, while their apices are connected with the ends of the optic filaments. As each cone is separated from its neighbors, it admits only a ray of light parallel with its axis, and its apex represents only a portion of the image, which must be made up, like a mosaic-work, of as many parts as there are cones in the eye. When the cones are of considerable length, it is evident, from their form and direction, their apices being directed inwards, that the oblique rays emanating from a luminous surface will be cut off, and that only those rays proceeding along the axis of the cone will produce an effect. Thus distinctness or sharpness of definition will be secured. The size of the visual field will depend on the form of the eye, the outermost cones marking its limits. Consequently the size of the visual field will depend on the size of the segment of the sphere forming its surface. The eyes of many insects have a field of about half a sphere, so that the creature will see objects before and behind it as well as those at the side. On the other hand, in many the eyes have scarcely any convexity, so that they must have a narrow field of vision.

A description of the simple eye will be found in the article ANATOMY, vol. i. p. 777 *sq.* Optically, it consists of a series of refractive media placed in front of the retina by which rays emanating from an external object are brought to a focus on that structure. In this article, we shall consider (1) the physical causes of vision; (2) the optical arrangements of the eye; (3) the specific influence of light on the retina; (4) sensations of color; (5) the movements of the eyes in vision; and (6) the psychical relations of luminous impressions.

1. PHYSICAL CAUSES OF VISION.

A luminous sensation may be excited by various modes of irritation of the retina or of the optic nerve. Pressure, cutting, or electrical shocks may act as stimuli, but the normal excitation is the influence of light on the retina. From a physical point of view, light is a mode of movement occurring in a medium, termed the ether, which pervades all space; but the physiologist studies the operation of these movements on the sentient organism as resulting in consciousness of the particular kind which we term a luminous impression. Outside of the body, such movements have been studied with great accuracy; but the physiological effects depend upon such complex conditions as to make it impossible to state them in the same precise way. Thus, when we look at the spectrum, we are conscious of the sensations of red and violet, referable to its two extremities: the physicist states that red is produced by 392 billions of impulses on the retina per second, and that violet corresponds to 757 billions per second; but he has arrived at this information by inductive reasoning, from many facts which have not at present any physiological explanation. We cannot at present trace any connection, as cause and effect, between 392 billions of impulses on the retina per second and a sensation of red. Below the red and above the violet ends of the spectrum there are vibrations which do not excite luminous sensations. In the first case, below the red, the effect as a sensation is heat; and above the violet the result is that of chemical activity. Thus the method of dispersion of light, as is followed in passing a ray through a prism, enables us to recognize these general facts:—(1) rays below the red excite thermal impressions; (2) from the lower red up to the middle of the violet, the thermal rays become gradually weaker until they have no effect; (3) from the lower red to the extreme violet, they cause luminous impressions, which reach their greatest intensity in the yellow; and (4) from about the end of the yellow to far beyond the extreme violet, the rays have gradually a less and less luminous effect, but they have the power of exciting such chemical changes as are produced in photography. In general terms, therefore, the lower end of the spectrum may be called thermal, the middle luminous, and the upper actinic or chemical; but the three merge into and overlap one another. It may be observed that the number of vibrations in the extreme violet is not double that of the low red, so that the sensibility of the eye to vibrations of light does not range through an octave. The ultra-violet rays may act on the retina in certain conditions, as when they are reflected by a solution of sulphate of quinine, constituting the phenomenon of fluorescence.

2. OPTICAL ARRANGEMENTS OF THE EYE.

(1.) *General.*—When light traverses any homogeneous transparent medium, such as the air, it passes on in a straight course with a certain velocity; but if it meet with any other transparent body of a different density, part of it is reflected or returned to the first medium, whilst the remainder is propagated through the second medium in a different direction and with a different velocity. Thus we may account for the phenomena of reflection and of refraction, for which see the article LIGHT. Let *a b*, in fig. 1, be a plane surface of some transparent substance, say a sheet of glass; a ray, *c d*, perpendicular to the surface, will pass through without refraction; but an oblique ray, *e f*, will be sent in the direction *e h*. If the ray *e h* had passed from a dense into a rarer medium, then the direction would have been *e g*. It might also be shown that the *sine* of the angle of incidence always bears a certain ratio to the *sine* of the angle of refraction; this ratio is termed the *index of refraction.* Thus, if a ray pass from air into water, the sine of the angle of incidence will have to the sine of the angle of the refraction the ratio of 4: 3, or $\frac{4}{3}$.

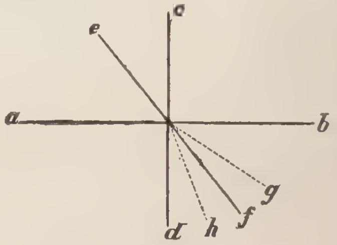


FIG. 1.—Refraction of Light.

Before a ray of light can reach the retina, it must pass through a number of transparent and refractive surfaces. The eye is a nearly spherical organ, formed of transparent parts situated behind each other, and surrounded by various membranous structures, the anterior part of which is also transparent. The transparent parts are—(1) the *cornea;* (2) the *aqueous humor*, found in the anterior chamber of the eye; (3) the *crystalline lens*, formed by a transparent convex body, the anterior surface of which is less convex than the posterior; and (4) the *vitreous humor*, filling the posterior chamber of the eye. The ray must therefore traverse the cornea, aqueous humor, lens, and vitreous humor. As the two surfaces of the cornea are parallel, the rays practically suffer no deviation in passing through that structure, but they are bent or refracted during their transmission through the other media.

From the optical point of view, the eye may be regarded as a *dioptric system* consisting of various refractive media. In such a system, as shown by Gauss, there are six cardinal points, which have a certain relation to each other. These are—

Two focal points; every ray passing through the *first* focal point becomes, after its refraction, parallel to the axis, and every ray which before refraction is parallel to the axis, passes after its refraction to the *second* focal point; (2) *Two principal points:* every ray which passes through the first point before refraction, passes after refraction through the second, and every ray which passes through any point of a plane elevated on a perpendicular axis from the first principal point (the *first principal plane*) passes through the corresponding point of an analogous plane raised upon the axis at the second principal point (the *second principal plane*); and (3) *Two nodal points,* which correspond to the optical centres of the two principal planes just alluded to. The distance of the first principal point from the first focal point is called the *anterior focal length,* and the term *posterior focal length* is applied to the distance of the posterior focal point from the second principal point. Listing has given the following measurements in millimetres from the centre of the cornea for the cardinal points in an ideal eye:

Anterior focal point........	12·8326.	First nodal point............	7·2420.
Posterior focal point.......	22·6470.	Second nodal point..........	7·6398.
First principal point.......	2·1746.	Anterior focal length......	15·0072.
Second principal point....	2·5724.	Posterior focal length.....	20·0746.

A view of such an ideal eye is shown in fig 2.

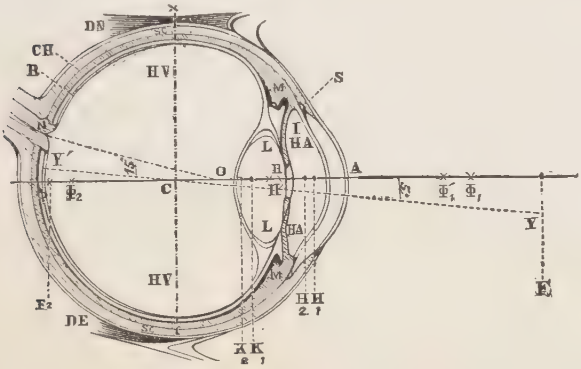

FIG. 2.—Transverse section of an Ideal or Schematique Eye.

A, Summit of cornea; SC, Sclerotic; S, Schlemm's canal; CH, Choroid; I, Iris; M, Ciliary muscle; R, Retina; N, Optic nerve; HA, Aqueous humor; L, Crystalline lens, the anterior of the double lines on its face showing its form during accommodation; HV, Vitreous humor; DN, Internal rectus muscle; DE, External rectus; YY′, Principal optical axis; ΦΦ, Visual axis, making an angle of 5° with the optical axis; C, Centre of the ocular globe. *The cardinal points of Listing*:—H_1H_2, principal points; K_1K_2, nodal points; F_1F_2, principal focal points. *The dioptric constants according to Giraud-Teulon*:—H, principal points united; $\phi_1\phi_2$, principal foci during the repose of accommodation; $\phi'_1\phi'_2$, principal foci during the maximum of accommodation; O, fused nodal points.

The remaining measurements of such an eye are as follows:—

Radii of curvature.

Of *anterior* face of cornea	= 8	millimetres.
Of *anterior* face of lens	= 10	"
Of *posterior* face of lens	= 6	"

Indices of Refraction.

Aqueous humor..................	$\frac{103}{77}$	= 1·3379
Crystalline lens..................	$\frac{16}{11}$	= 1·4545
Vitreous humor..................	$\frac{103}{77}$	= 1·3379

The optical constants of the human eye may be still further simplified by assuming that the two principal points and the two nodal points respectively are identical. Thus we may construct a *reduced eye*, in which the principal point is 2·3448 mm. behind the cornea, and the nodal point is 7·4969 mm., having an anterior focal length of 15 mm. and a posterior focal length of 20 mm. The refracting surface, or lens, has a radius of 5 mm., and is 3 mm. behind the cornea; and the index of refraction is that of the aqueous humor, or $\frac{103}{77}$.

(2.) *The Formation of an Image on the Retina.*—This may be well illustrated with the aid of an ordinary photographic camera. If properly focused, an inverted image will be seen on the glass plate at the back of the camera. It may also be observed by bringing the eye-ball of a rabbit near a candle flame. The action of a lens in forming an inverted image is illustrated by fig. 3, where the pencil of rays proceeding from a is brought to a focus at a', and those from b at b', consequently the image of a b is inverted as at b' a'. The three characteristic features of the retinal image are—(1) it is reversed; (2) it is sharp and well defined if it be accurately focused on the retina; and (3) its size depends on the visual angle. If we look at a distant object, say a star, the rays reaching the eye are parallel, and in passing through the refractive media, they are focused at the posterior focal point,—that is, on the retina. A line from the luminous point on the retina passing through the nodal point is called the *line of direction.* If the luminous object be not nearer than, say, 60 yards, the image is still brought to a focus on the retina without any effort on the part of the eye. Within this distance, supposing the condition of the eye to be the same as in looking at a star, the image would be formed somewhat behind the posterior focal point, and the effect would be an indistinct impression on the retina. To obviate this, for near distances, accommodation, so as to adapt the eye, is effected by a mechanism to be afterwards described.

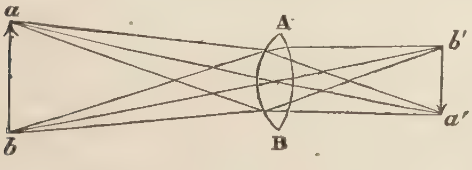

FIG. 3.—Inversion by action of a Lens.

When rays, reflected from an object or coming from a luminous point, are not brought to an accurate focus on the retina, the image is not distinct in consequence of the formation of what are called *circles of diffusion*, the production of which will be rendered evident by fig. 4. From the point A luminous rays enter the eye in the form of a cone, the kind of which will depend on the pupil. Thus it may be circular, or oval, or even triangular. If the pencil is focused in front of the retina, as at d, or behind it as at f, or, in other words, if the retina, in place of being at F, be in the positions G or H, there will be a luminous circle or a luminous triangular space, and many elements of the retina will be affected. The size of these diffusion circles depends on the distance from the retina of the point where the rays are focused; the greater the distance, the more extended will be the diffusion circle. Its size will also be affected by the greater or less diameter of the pupil. Circles of diffusion may be readily studied by the following experiment, usually called the experiment of Scheiner:—

Let C be a lens, and D E F be screens placed behind it; hold in front of the lens a card perforated by two holes A and B, and allow rays from a luminous point a to pass through these holes; the point o on the screen E will be exact focus of the rays emanating from a; if a were removed farther from the lens, the focus would be on F, and if it were brought near to C, the focus would then be on D. The screens F and D show two images of the point a. If, then, we close the upper opening in A B, the *upper* image m on F, and the *lower* image n on D, disappear. Suppose now that the retina be substituted for the screens D and F, the contrary will take place, in consequence of the reversal of the retinal image. If the eye be placed at o, only one image will be seen; but if it be placed either in the plane of F or D, then two images will be seen, as at m m, or n n; consequently in either of these planes there will be circles of diffusion and indistinctness, and only in the plane E will there be sharp definition of the image.

To understand the formation of an image on the retina, suppose a line drawn from each of its two extremities to the nodal point and continued onwards to the retina, as in fig. 6, where the visual angle is x. It is evident that its size will depend on the size of the object and the distance of the object from the eye. Thus, also, objects of different sizes, c, d, e, in fig. 6, may be included in the same visual angle, as they are at different distances from the eye. The size of the retinal image may obviously be calculated if we know the size of the object, its distance from the nodal point o, and the distance of the nodal point from the posterior focus. Let A be the size of the object, B its dis-

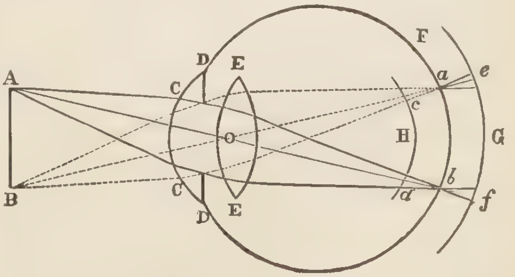

FIG. 4.—Formation of Circles of Diffusion.

tance from the nodal point, and C the distance of *o* from the retina, or 15 mm.; then the size of the retinal image $x=\frac{A+15}{B}$. The smallest visual angle in which two distinct points may be observed is 60 seconds; below this, the two sensations fuse into one; and the size of the retinal image corresponding to this angle is ·004 mm., nearly the diameter of a single retinal rod or cone. Two objects, therefore, included in a visual angle of less than 60 seconds, appear as one point. A small visual angle is in most eyes a condition of sharpness of definition. With a large angle, objects appear less sharply marked. Acuteness is determined by a few retinal elements, or even only one, being affected. A very minute image, if thrown on a single retinal element, is apparently sufficient to excite it. Thus it is possible to see a brilliant point in an angle even so small as $\frac{1}{4}$ of a second, and a sharp eye can see a body the $\frac{1}{50}$th of a line in diameter, that is, about the $\frac{1}{600}$th part of an inch.

(3.) *The Optical Defects of the Eye.*—As an optical instrument, the eye is defective; but from habit, and want of attention, its defects are not appreciated, and consequently they have little or no influence on our sensations. These defects are chiefly of two kinds—(1) those due to the curvature of the refractive surfaces, and (2) those due to the dispersion of light by the refractive media.

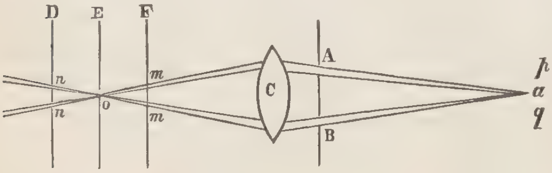

Fig. 5.—Diagram illustrating the experiment of Scheiner.

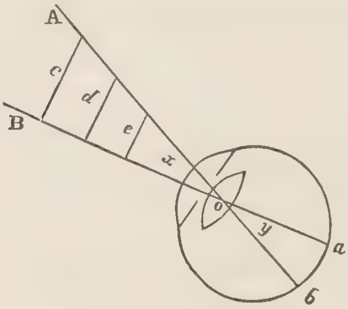

Fig. 6.—The Visual Angle.

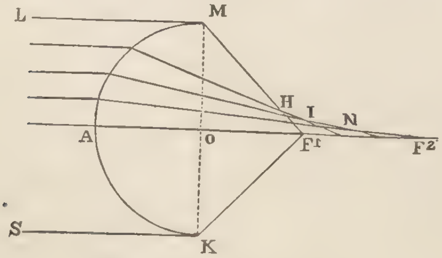

Fig. 7.—Spherical Aberration.

(*a*) *Aberration of Sphericity.*—Suppose, as in fig. 7, M A K to be a refractive surface on which parallel rays from L to S impinge, it will be seen that those rays passing near the circumference are brought to a focus at F^1, and those passing near the centre at F^2,—intermediate rays being focused at N. Thus on the portion of the axis between F^1 and F^2 there will be a series of focal points, and the effect will be a blurred and bent image. In the eye this defect is to a large extent corrected by the following arrangements:—(1) the iris cuts off the outer and more strongly refracted rays; (2) the curvature of the cornea is more ellipsoidal than spherical, and consequently those farthest from the axis are least deviated; (3) the anterior and posterior curvatures of the lens are such that the one corrects, to a certain extent, the action of the other; and (4) the structure of the lens is such that its power of refraction diminishes from the centre to the circumference, and consequently the rays farthest from the axis are less refracted.

(*b*) *Astigmatism.*—Another defect of the eye is due to different meridians having different degrees of curvature. This defect is known as *astigmatism.* It may be thus detected. Draw on a sheet of white paper a vertical and a horizontal line with ink, crossing at a right angle; at the point of distinct vision, it will be found impossible to see the lines with equal distinctness at the same time: to see the horizontal line distinctly the paper must be brought near the eye, and removed from it to see the vertical. In the cornea the vertical meridian has a shorter radius of curvature, and is consequently more refractive than the horizontal. The meridians of the lens may also vary; but, as a rule, the asymmetry of the cornea is greater than that of the lens. The optical explanation of the defect will be understood with the aid of fig. 8.

Thus, suppose the vertical meridian C A D to be more strongly curved than the horizontal F A E, the rays which fall on C A D will be brought to a focus G, and those falling on F A E at B. If we divide the pencil of rays at successive points, G, H, I, K, B, by a section perpendicular to A B, the various forms it would present at these points are seen in the figures underneath, so that if the eye were placed at G, it would see a horizontal line *a a′*; if at H, an ellipse with the long axis *a a′* parallel to A B; if at I, a circle; if at K, an ellipse, with the long axis, *b c*, at right angles to A B; and if at B, a vertical line *b c*. The degree of astigmatism is ascertained by measuring the difference of refraction in the two chief meridians; and the defect is corrected by the use of cylindrical glasses, the curvature of which, added to that of the minimum meridian, makes its focal length equal to that of the maximum meridian.

(*c*) *Aberration of Refrangibility.*—When a ray of white light traverses on a lens, the different rays composing it, being unequally refrangible, are dispersed: the violet rays (see fig. 9), the most refrangible, are brought to a focus at *e*, and the red rays, less refrangible, at *d*. If a screen were placed at *e*, a series of concentric colored circles would be formed, the central being of a violet, and the circumference of a red color. The reverse effect would be produced if the screen were placed at *d*. Imagine the retina in place of the screen in the two positions, the sensational effects would be those just mentioned. Under ordinary circumstances, the error of refrangibility due to the optical construction of the eye is not observed, as for vision at near distances the interval between the focal point of the red and violet rays is very small. If, however, we look at a candle flame through a bit of cobalt-blue glass, which transmits only the red and blue rays, the flame may appear violet surrounded by blue, or blue surrounded by violet, according as we have accommodated the eye for different distances. Red surfaces always appear nearer than violet surfaces situated in the same plane, because the eye has to be accommodated more for the red than for the violet, and consequently we imagine them to be nearer. Again, if we contemplate red letters or designs on a violet ground the eye soon becomes fatigued, and the designs may appear to move.

(*d*) *Defects due to Opacities, etc., in the Transparent Media.*—When small opaque particles exist in the transparent media, they may cast their shadow on the retina so as to give rise to images which are projected outwards by the mind into space, and thus appear to exist outside of the body. Such phenomena are termed entoptic. They may be of two kinds:—(1) *extra-retinal*, that is, due to opaque or semi-transparent bodies in any of the refractive structures anterior to the retina, and presenting the appearance of drops, striæ, lines, twisted bodies, forms of grotesque shape, or minute black dots dancing before the eye; and (2) *intra-retinal*, due to opacities, etc., in the layers of the retina, in front of Jacob's membrane. The intra-retinal may be produced in a normal eye in various ways. (1) Throw a strong beam of light on the edge of the sclerotic, and a curious branched figure will be seen, which is an image of the retinal vessels. The construction of these images, usually called *Purkinje's figures*, will be understood from fig. 10. Thus, in the figure to the left, the rays passing through the sclerotic at b'', in the direction $b''c$, will throw a shadow of a vessel at c on the retina at b', and this will appear as a dark line at B. If the light move from b'' to a'', the retinal shadow will move from b' to a', and the line in the field of vision will pass from B to A. It may be shown that the distance $c\,b'$ corresponds to the distance of the retinal vessels from the layer of rods and cones (see ANATOMY, vol. i. p. 780). If the light enter the cornea, as in the figure to the right, and if the light be moved, the image will be displaced in the same direction as the light, if the movement does not extend beyond the middle of the cornea, but in the opposite direction to the light when the latter is moved up and down. Thus, if a be moved to a', d will be moved to d', the shadow on the retina from c to c', and the image b to b'. If, on the other hand, a be moved above the plane of the paper, d will move below, consequently c will move above, and b' will appear to sink. (2) The retinal vessels may also be seen by looking at a strong light through a minute aperture, in front of which a rapid to and fro movement is made. Such experiments prove that the sensitive part of the retina is its deepest and most external layer (Jacob's membrane).

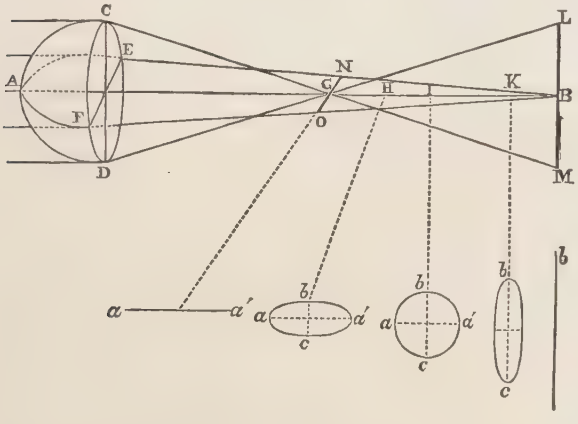

FIG. 8.—Diagram illustrating Astigmatism.

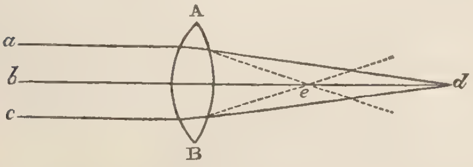

FIG. 9.—Diagram illustrating the Dispersion of Light by a Lens.

(4.) *Accommodation, or the Mechanism of Adjustment for Different Distances.*—When a camera is placed in front of an object, it is necessary to focus accurately in order to obtain a clear and distinct image on the sensitive plate. This may be done by moving either the lens or the sensitive plate backwards or forwards so as to have the posterior focal point of the lens corresponding with the sensitive plate. For similiar reasons, a mechanism of adjustment, or accommodation for different distances, is necessary in the human eye. In the normal eye, any number of parallel rays, coming from a great distance, are focused on the retina. Such an eye is termed *emmetropic* (fig. 11, A). Another form of eye (B) may be such that parallel rays are brought to a focus *in front of* the retina. This form of eye is *myopic* or short-sighted, inasmuch as, for distinct vision, the object must be brought near the eye, so as to catch the divergent rays, which are then focused on the retina. A third form is seen in C, where the focal point, for ordinary distances, is *behind* the retina, and consequently the object must be held far off, so as to allow only the less divergent or parallel rays to reach the eye. This kind of eye is called *hypermetropic*, or far-sighted. For ordinary distances, at which objects must be seen distinctly in every-day life, the fault of the myopic eye may be corrected by the use of concave and of the hypermetropic by convex glasses. In the first case, the concave glass will remove the posterior focal point a little farther back, and in the second the convex glass will bring it farther forwards; in both cases, however, the glasses may be so adjusted, both as regards refractive index and radius of curvature, as to bring the rays to a focus on the retina, and consequently secure distinct vision.

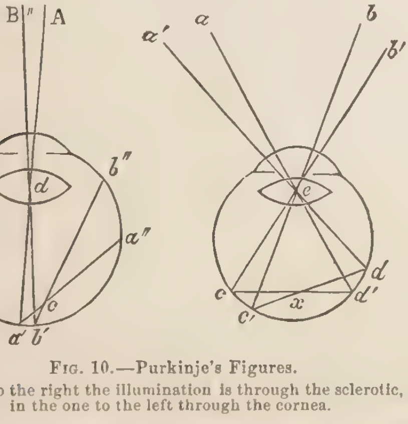

FIG. 10.—Purkinje's Figures.

In the eye to the right the illumination is through the sclerotic, and in the one to the left through the cornea.

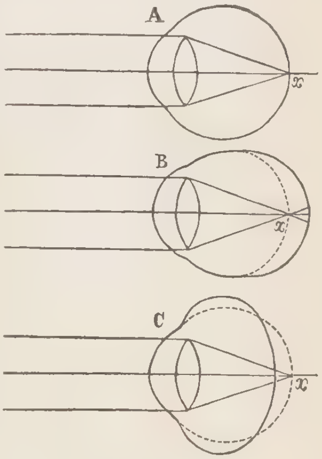

Fig. 11.

A, Emmetropic or normal eye; B, Myopic or short-sighted eye; C, Hypermetropic or long-sighted eye.

From any point 65 metres distant, rays may be regarded as almost parallel, and the point will be seen without any effort of accommodation. This point, either at this distance or in infinity, is called the *punctum remotum*, or the most distant point seen without accommodation. In the myopic eye it is much nearer and for the hypermetropic there is really no such point, and accommodation is always necessary. If an object were brought too close to the eye for the refractive media to focus it on the retina, circles of diffusion would be formed, with the result of causing indistinctness of vision, unless the eye possessed some power of adapting itself to different distances. That the eye has some such power of accommodation is proved by the fact that, if we attempt to look through the meshes of a net at a distant object, we cannot see both the meshes and the object with equal distinctness at the same time. Again, if we look continuously at very near objects, the eye speedily becomes fatigued. Beyond a distance of 65 metres, no accommodation is necessary; but within it, the condition of the eye must be adapted to the diminished distance until we reach a point near the eye which may be regarded as the limit of visibility for near objects. This point, called the *punctum proximum*, is usually 12 centimetres (or about 4 inches) from the eye. The range of accommodation is thus from the *punctum remotum* to the *punctum proximum*.

The mechanism of accommodation has been much disputed, but there can be no doubt it is chiefly effected by a change in the curvature of the anterior surface of the crystalline lens. If we hold a lighted candle in front and a little to the side of an eye to be examined, three reflections may be seen in the eye, as represented in fig. 12. The first, a, is erect, large, and bright, from the anterior surface of the cornea; the second, b, also erect, but dim, from the anterior surface of the crystalline lens; and the third, c, inverted, and very dim, from the posterior surface of the lens, or perhaps the concave surface of the vitreous humor to which the convex surface of the lens is adapted. Suppose the three images to be in the position shown in the figure for distant vision, it will be found that the middle image *b* moves towards *a*, on looking at a *near* object. The change is due to an alteration of the curvature of the lens, as shown in fig. 13. The changes occurring during accommodation are:—(1) the curvature of the anterior surface of the crystalline lens increases, and may pass from 10 to 6 mm.; (2) the pupil contracts; and (3) the intraocular pressure increases in the posterior part of the eye. An explanation of the increased curvature of the anterior surface of the lens during accommodation has been thus given by Helmholtz. In the normal condition, that is, for the emmetropic eye, the crystalline lens is flattened anteriorly by the pressure of the anterior layer of the capsule; during accommodation, the radiating fibres of the ciliary muscle pull the ciliary processes forward, thus relieving the tension of the anterior layer of the capsule, and the lens at once bulges forward by its elasticity. The exact mechanism of the ciliary muscle is still not clearly understood.

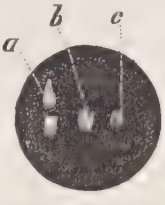

Fig. 12.—Reflected images in the Eye.

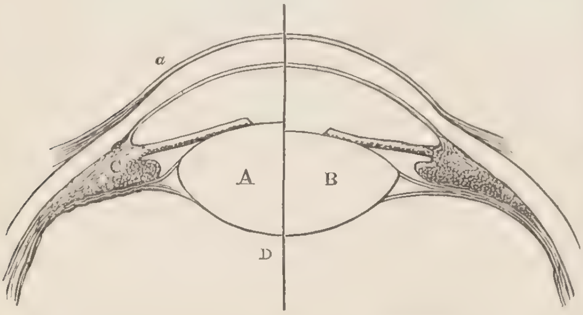

Fig. 13.—Mechanism of Accommodation.

A, The lens during accommodation, showing its anterior surface advanced; B, The lens as for distant vision; C, Position of the ciliary muscle.

Helmholtz has succeeded in measuring with great accuracy the sizes of these reflected images by means of an instrument termed an ophthalmometer, the construction of which is based on the following optical principles. When a luminous ray traverses a plate of glass having parallel sides, if it fall perpendicular to the plane of the plate, it will pass through without deviation; but if it fall obliquely on the plate (as shown in the left-hand diagram in fig. 14) it undergoes a lateral deviation, but in a direction parallel to that of the incident ray, so that to an eye placed behind the glass plate, at the lower A, the luminous point, upper A, would be in the direction of the prolonged emergent ray, and thus there would be an apparent lateral displacement of the point, the amount of which would increase with the obliquity of the incident ray. If, instead of one plate, we take two plates of equal thickness, one placed above the other, two images will be seen, and by turning the one plate with reference to the other, each image may be displaced a little to one side. The instrument consists of a small telescope (fig. 14) T, the axis of which coincides with the plane separating the two glass plates C C and B B. When we look at an object X Y, and turn the plates till we see two objects *xy*, *xy* touching each other, the size of the image X Y will be equal to the distance the one object is displaced to the one side and the other object to the other side. Having thus measured the size of the reflection, it is not difficult, if we know the size of the object reflecting the light and its distance from the eye, to calculate the radius of the curved surface. (See Woinow's *Ophthalmometrie*, St. Petersburg, 1871, and an account given in Appendix to M'Kendrick's *Outlines of Physiology*, 1878.) The general result is that, in accommodation for near objects, the middle reflected image becomes smaller, and the radius of curvature of the anterior surface of the lens becomes shorter.

(5.) *Absorption and Reflection of Luminous Rays from the Eye.* When light enters the eye, it is partly absorbed by the black pigment of the choroid and partly reflected. The reflected rays are returned through the pupil, not only following the same direction as the rays entering the eye, but uniting to form an image at the same point in space as the luminous object. The pupil of an eye appears black to an observer, because the eye of the observer does not receive any of those reflected rays. If, however, we strongly illuminate the retina, and hold a lens in front of the eye, so as to bring the reflected rays to a focus nearer the eye, then a virtual and erect, or a real and reversed, image of the retina will be seen. Such is the principle of the ophthalmoscope, invented by Helmholts in 1851. Eyes deficient in pigment, as in albinos, appear luminous, reflecting light of a red or pink color; but if we place in front of such an eye a card perforated by a round hole of the diameter of the pupil, the hole will appear quite dark, like the pupil of an ordinary eye. In many animals a portion of the fundus of the eyeball has no pigment, and presents an iridescent appearance. This is called a *tapetum*. It probably renders the eye more sensitive to light of feeble intensity.

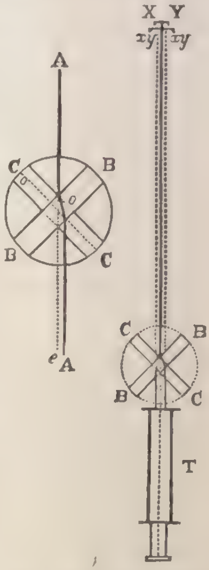

Fig. 14.—Diagrammatic view of the Ophthalmometer of Helmholtz.

(6.) *Functions of the Iris.*—The iris constitutes a diaphragm which regulates the amount of light entering the eyeball. The aperture in the centre, the *pupil*, may be dilated by contraction of a system of radiating fibres of involuntary muscle, or contracted by the action of another system of fibres, forming a sphincter, at the margin of the pupil. The radiating fibres are controlled by the sympathetic, while those of the circular set are excited by the third cranial nerve. The variations in diameter of the pupil are determined by the greater or less intensity of the light acting on the retina. A strong light causes contraction of the pupil; with light of less intensity, the pupil will dilate. In the human being, a strong light acting on one eye will often cause contraction of the pupil, not only in the eye affected, but in the other eye. These facts indicate that the phenomenon is of the nature of a reflex action, in which the fibres of the optic nerve act as sensory conductors to a centre in the encephalon, whence influences emanate which affect the pupil. It has been ascertained that if the fibres of the optic nerve be affected in any way, contraction of the pupil follows. The centre is probably in the anterior pair of the corpora quadrigemina, as destruction of these bodies causes immobility of the pupil. On the other hand, the dilating fibres are derived from the sympathetic; and it has been shown that they come from the lower part of the cervical, and upper part of the dorsal, region of the cord. But the iris seems to be directly susceptible to the action of light. Thus, as was first pointed out by Brown-Séquard, the pupil of the eye of a dead animal will contract if exposed to light for several hours, whereas, if the eye on the opposite side be covered, its pupil will remain widely dilated, as at the moment of death.

The pupil *contracts* under the influence—(1) of an increased intensity of light; (2) of the effort of accommodation for near objects; (3) of a strong convergence of the two eyes; and (4) of such active substances as nicotine, morphia, and physostigmine; and it *dilates* under the influence —(1) of a diminished intensity of light; (2) of vision of distant objects; (3) of a strong excitation of any sensory nerve; (4) of dyspnœa; and (5) of such substances as atropine and hyoscyamine. The chief function of the iris is to so moderate the amount of light entering the eye as to secure sharpness of definition of the retinal image. This it accomplishes by (1) diminishing the amount of light reflected from near objects, by cutting off the more divergent rays and admitting only those approaching a parallel direction, which in a normal eye, are focused on the retina; and (2) preventing the error of spherical aberration by cutting off divergent rays which would otherwise impinge near the margins of the lens, and would thus be brought to a focus in front of the retina.

3. Specific Influence of Light on the Retina.

The retina is the terminal organ of vision, and all the parts in front of it are merely optical arrangements for securing that an image will be accurately focused upon it. The natural stimulus of the retina is light. It is often said that it may be excited by mechanical and electrical stimuli: but such an observation really applies to the stimulation of the fibres of the optic nerve. It is well known that such stimuli applied to the optic nerve behind the eye produce always a luminous impression; but there is no proof that the retina, strictly speaking, is similarly affected. Pressure or electrical currents may act on the eyeball, but in doing so they not only affect the retina, consisting of its various layers and of Jacob's membrane, but also the fibres of the optic nerve. It is probable that the retina, by which is meant all the layers except those on its surface formed by the fibres of the optic nerve, is affected only by its *specific* kind of stimulus, light. This stimulus so affects the terminal apparatus as to set up actions which in turn stimulate the optic fibres. The next question naturally is,—What is the specific action of light on the retina? Professors Holmgren of Upsala individually, and Dewar and M'Kendrick conjointly, have shown that when light falls on the retina it excites a variation of the natural electrical current obtained from the eye by placing it on the cushions of a sensitive galvanometer. The general effect was that the *impact* of light caused an increase in the natural electrical current, —during the *continuance* of light, the current diminished slowly, and fell in amount even below what it was before the impact,—and that the *withdrawal* of light was followed by a rebound, or second increase, after which the current fell in strength, as if the eye suffered from fatigue.

It was also observed in this research that the amount of electrical variation produced by light of various intensities corresponded pretty closely to the results expressed by Fechner's law, which regulates the relation between the stimulus and the sensational effect in sensory impressions. This law is, that the sensational effect does not increase proportionally to the stimulus, but as the logarithm of the stimulus. Thus, supposing the stimulus to be 10, 100, or 1000 times increased, the sensational effect will not be 10, 100, or 1000 times, but only 1, 2, and 3 times greater. This law, then, applies to the phenomena happening in the terminal organ, and not, as generally supposed, exclusively to those occurring in the brain.

Such electrical phenomena probably result either from thermal or chemical changes in the retina. Recent researches of Boll and Kühne have shown that light produces chemical changes in the retina. If an animal be killed in the dark, and if its retina be exposed only to *yellow* rays, the retina has a peculiar purple color, which is at once destroyed by exposure to ordinary light. The purple matter apparently is decomposed by light. Kühne has also shown that an image may actually be *fixed* on the retina by plunging it into a solution of alum immediately after death. Thus it would appear that light affects the purple-matter of the retina, and the result of this chemical change is to stimulate the optic filaments; if the action be arrested, we may have a picture on the retina, but if it be not arrested, the picture is evanescent; the purple-matter is used up, and new matter of a similar kind is formed to take its place. The retina might, therefore, be compared to a sensitive plate having the sensitive matter quickly removed and replaced by chemical changes; and it is probable that the electrical expression of these changes is what has been above described.

(*a*) *Phosgenes.*—Luminous impressions may also be produced by pressure on the eyeball. Such impressions, termed *phosgenes*, usually appear as a luminous centre surrounded by colored or dark rings. Sometimes they seem to be small bright scintillations of various forms. Similar appearances may be observed at the moments of opening or of closing a strong electrical current transmitted through the eyeball.

(*b*) *The Retina's Proper Light.*—The visual field, even when the eyelids are closed in a dark room, is not absolutely dark. There is a sensation of faint luminosity which may at one moment be brighter than at another. This is often termed the *proper light of the retina*, and it indicates a certain condition of molecular activity, even in darkness.

(*c*) *The Excitability of the Retina.*—The retina is not equally excitable in all its parts. At the entrance of the optic nerve, as was shown by Mariotte in 1668, there is no sensibility to light. Hence, this part of the retina is called the *blind spot*. If we shut the left eye, fix the right eye on the cross seen in fig. 15, and move the book towards and away from the eye, a position will be found when the round spot disappears, that is when its image falls on the entrance of the optic nerve. There is also complete insensibility to colors at that spot. The diameter of the optic papilla is about 1·8 mm., giving an angle of 6 degrees; this angle determines the apparent size of the blind spot in the visual field, and it is sufficiently large to cause a human figure to disappear at a distance of two metres (Beaunis).

Fig. 15—Diagram for the study of the *Blind Spot*.

The *yellow spot* in the centre of the retina is the most sensitive to light, and it is chiefly employed in direct vision. Thus, if we fix the eye on a word in the centre of this line, it is distinctly and sharply seen, but the words towards each end of the line are vague. If we wish to see each word distinctly, we "run the eye" along the line,—that is, we bring each successive word on the yellow spot. This spot has a horizontal diameter of 2 mm., and a vertical diameter of ·8 mm.; and it corresponds in the visual field to an angle of from 2 to 4 degrees. It is believed that the fossa in the spot, where there are almost no retinal elements except Jacob's membrane, consisting here entirely of cones (2000 in number), is the area of most acute sensibility. This fossa has a diameter of only ·2 mm., which makes the angle ten times smaller. Thus the field of distinct vision is extremely limited, and at the same moment we see only a very small portion of the visual field. Images of external objects are brought successively on this minute sensitive area, and the different sensations seem to be fused together, so that we are conscious of the object as a whole.

Towards the anterior margin of the retina sensitiveness to light becomes diminished; but the diminution is not uniform, and it varies in different persons.

(*d*) *Duration and Persistence of Retinal Impressions.*—To excite the retina, a feeble stimulus must act for a certain time; when the retina is excited, the impression lasts after the cessation of the stimulus; but if the stimulus be strong, it may be of very short duration. Thus the duration of an electrical spark is extremely short, but the impression on the retina is so powerful, and remains so long, as to make the spark visible. If we rotate a disc having white and black sectors we see continuous dark bands. Even if we paint on the face of the disc a single large round red *spot*, and rotate rapidly, a continuous red *band* may be observed. Here the impressions of red on the same area of retina succeed each other so rapidly that before one disappears another is superadded, the result being a fusion of the successive impressions into one continuous sensation. This phenomenon is called the *persistence of retinal impressions*. It has been ascertained that an impression lasts on the retina from $\frac{1}{50}$ to $\frac{1}{30}$ of a second. If we look steadily at a bright light for a few seconds and then quickly close the eyes or gaze into a dark room, a luminous image of the light will be visible for a short time. Such an appearance is called a *positive accidental image*, or a consecutive image. It may also be observed in this experiment that the intensity of the retinal excitation is not uniform. It increases quickly at its commencement, and after it has reached a maximum it slowly declines. Many familiar toys, such as the thaumatrope, or wheel of life, stroboscopic discs, and the phenakistoscope, produce curious effects due to persistence of retinal impressions.

(*e*) *The Phenomena of Irradiation.*—If we look at fig. 16, the white square in the black field appears to be larger than the black square in the white field, although both are of precisely the same size. This is due to *irradiation*, a phenomenon explained by Helmholtz, by stating that the borders of clear surfaces advance in the visual field and encroach on obscure surfaces. Probably, even with the most exact accommodation, diffusion images form round the image of a white surface on a black ground, forming a kind of penumbra, thus causing it to appear larger than it really is.

(*f*) *Intensity of Light required to excite the Retina.*—Light must have a certain intensity to produce a luminous impression. It is impossible to fix the minimum intensity necessary, as the effect will depend, not only on the intensity of the stimulus, but on the degree of retinal excitability at the time. Thus, after the retina has been for some time in the dark, its excitability is increased; on the other hand, it is much diminished by fatigue. Aubert has stated that the minimum intensity is about 300 times less than that of the full moon. The sensibility of the eye to light is measured by *photometers*, instruments which will be described under the article LIGHT.

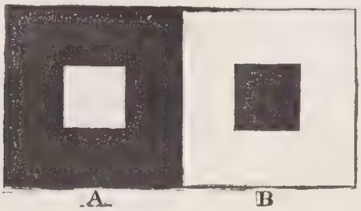

FIG. 16.—Illustrating the effect of irradiation.

(*g*) *Consecutive Retinal Images.*—Images which persist on the retina are either positive or negative. They are termed *positive* when the bright and obscure parts of the image are the same as the bright and obscure parts of the object; and *negative*, when the bright parts of the object are dark in the image, and *vice versâ*. Positive images are strong and sharply marked when an intense light has acted for not less than $\frac{1}{3}$ of a second. If the excitation be continued much longer, a negative and not a positive image will be seen. If, when the positive image is still visible, we look on a very brilliantly illuminated surface, a negative image appears. Negative images are seen with greatest intensity after a strong light has acted for a considerable time. These phenomena may be best studied when the retina is very excitable, as in the morning after a sound sleep. On awakening, if we look steadily *for an instant* at the window and then close the eyes, a *positive* image of the window will appear; if we then gaze fixedly at the window for one or two minutes, close the eyes two or three times, and then look at a dark part of the room, a *negative* image will be seen floating before us. The positive image is due to excitation of the retina, and the negative to fatigue. If we fatigue a small area of the retina with white light, and then allow a less intense light to fall on it, the fatigued area responds feebly, and consequently the object, such as the window pane, appears to be dark. Many curious experiments may be made to illustrate the laws of consecutive images. Thus, if we look at a black figure on a white ground for, say, one minute, and then gaze into a dark part of the room, a gigantic *white* figure, of corresponding shape, may make its appearance. A white figure on a black ground will produce a black image, a green figure will produce a red, and a red a green,—the reproduced color being always complementary to that of the figure.

4. SENSATIONS OF COLOR.

(1.) *General Statement.*—Color is a special sensation excited by the action on the retina of rays of light of a definite wave length. Thus we have a sensation of red when a certain number of waves of light impinge on the retina in a unit of time, and with about twice the number of waves in the same time the sensation will not be of red but of violet. When we examine a spectrum, we see a series of colors merging by insensible gradations the one into the other, thus:—red, orange, yellow, green, blue, and violet. These are termed *simple* colors. If two or more colored rays of the spectrum act simultaneously on the same spot of the retina, they may give rise to sensations of *mixed colors*. These mixed colors are of two kinds:—(1) those which do not correspond to any color in the spectrum, such as purple and white, and (2) those which do exist in the spectrum. White may be produced by a mixture of two simple colors, which are then said to be *complementary*. Thus, red and greenish-blue, orange and cyanic-blue, yellow and indigo-blue, and greenish-yellow and violet all produce white. Purple is produced by a mixture of red and violet, or red and bluish-violet. When white light falls on a surface, the surface may absorb all the rays except the red. If the red rays are alone reflected, then the object will be red; if the green rays are reflected, then the object will appear to be green. Again, if we look through red glass, all the rays are absorbed except red, and consequently the world beyond appears to be red. So with regard to the other transparent colored media. The following table by Helmholtz shows the compound colors produced by mixing other colors:—

	Violet	Indigo-blue	Cyanic-blue	Greenish-blue	Green	Yellowish-green	Yellow
Red	Purple	Deep rose	White rose	*White*	Whitish-yellow	Golden yellow	Orange
Orange	Deep-rose	White rose	*White*	Whitish-yellow	Yellow	Yellow	
Yellow	White rose	*White*	Whitish-green	Whitish-green	Yellowish-green		
Yellowish-green	*White*	Green	Green	Green			
Green	Blue	Water-blue	Greenish-blue				
Greenish-blue	Water-blue	Water-blue					
Cyanic blue	Indigo-blue						

This table shows that if we mix two simple colors, not so far separated in the spectrum as the complementary colors, the mixed color contains more white as the interval between the colors employed is greater, and that if we mix two colors further distant in the spectrum than the complementary colors, the mixture is whiter as the interval is smaller. By mixing more than two simple colors, no new colors are produced, but only different *shades* of color.

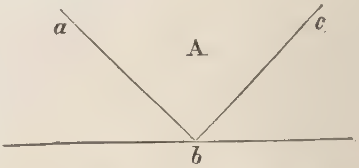

FIG. 17.—Form of double slit for the partial superposition of two spectra.

(2) *Modes of Mixing Color-Sensations.*—Various methods have been adopted for studying the effect of mixing colors.

(*a*) *By Superposing two Spectra* (Helmholtz and Clerk Maxwell).—This may be done in a simple way by having a slit in the form of the letter V (see fig. 17), of which the two portions *a b* and *b c* form a right angle; behind this slit is placed a vertical prism, and two spectra are obtained, as seen in fig. 18, in which *b f e a* is the spectrum of the slit *a b*, and *c e f d* that of the slit *b c;* the colored spectra

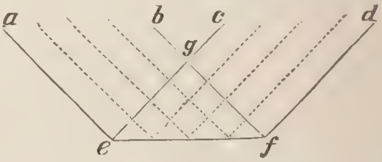

FIG. 18.—Diagram of double spectrum partially superposed.

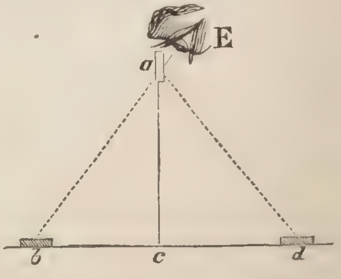

FIG. 19.—Diagram showing Lambert's method of mixing sensations of color.

are contained in the triangle *g e f*, and, by arrangement, the effects of mixture of any two simple colors may be observed.

(*b*) *By Lambert's Method of Reflection.*—Place a red wafer on *b*, in fig. 19, and a blue wafer on *d*, and so angle a small glass plate *a* as to transmit to the eye a reflection of the blue wafer on *d* in the same line as the rays transmitted from the red wafer on *b*. The sensation will be that of purple; and by using wafers of different colors, many experiments may thus be performed.

(*c*) *By the use of Rotating Discs which quickly superpose on the same Area of Retina different Impressions of Color.*—Such discs may be constructed of cardboard, on which colored sectors are painted, as shown in fig. 20, representing diagrammatically the arrangement of Sir Isaac Newton. The angles of the sectors were thus given by him:—

Red	60° 45·5′	Green	60° 45·5′
Orange	34° 10·5′	Blue	54° 41′
Yellow	54° 41′	Indigo	34° 10·5′
Violet	60° 45·5′.		

With sectors of such a size, *white* will be produced on rotating the disc rapidly. This method has been carried out with great efficiency by the color-top of Clerk Maxwell. It is simply a flat top, on the surface of which discs of various colors may be placed. Dancer has added to it a method by which, even while the top is rotating rapidly, and the sensation of a mixed color is strongly perceived, the eye may be able to see the *simple* colors of which it is composed. This is done by placing on the handle of the top, a short distance above the colored surface, a thin black disc, perforated by holes of various size and pattern, and weighted a little on one side. This disc vibrates to and fro rapidly, and breaks the continuity of the color-impression; and thus the constituent colors are readily seen.

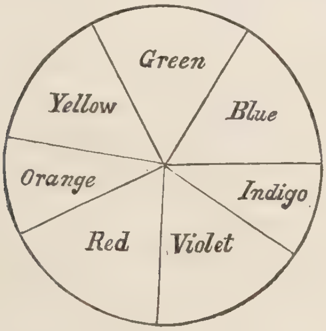

FIG. 20.—Diagram of the Color Disc of Sir Isaac Newton.

(3.) *Physiological Characters of Colors.*—All colors have three special characters:—(1) *Tone*, depending on the number of vibrations per second; (2) *Intensity*, depending on the extent or amplitude of the vibrations, and passing from the most sombre to the most brilliant shades; and (3) *Saturation*, which depends on the amount of *white* the color contains; thus, it is saturated when there is no white, as in the pure colors of the spectrum, and there may be an infinite number of degrees of saturation from the pure color to white.

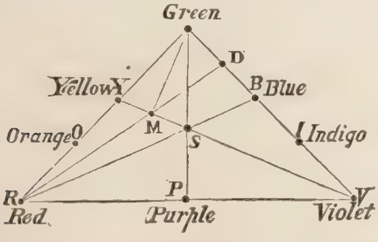

FIG. 21.—Geometrical representation of the relations of colors as shown by Newton.

(4.) *The Geometric Representation of Colors.*—Colors may be arranged in a linear series, as in the solar spectrum. Each point of the line corresponds to a determinate impression of color; the line is not a straight line, as regards luminous effect, but is better represented by a curve, passing from the red to the violet. This curve might be represented as a circle in the circumference of which the various colors might be placed, in which case the complementary colors would be at the extremities of the same diameter. Newton arranged the colors in the form of a triangle, as shown in fig. 21. If we place three of the spectral colors at three angles, thus,—green, violet, and red,—the sides of the triangle include the intermediate colors of the spectrum, except purple.

The point S corresponds to white, consequently, from the intersection of the lines which join the complementary colors, the straight lines from green to S, R S, and V S, represent the amount of green, red, and violet necessary to form white; the same holds good for the complementary colors: for example, for blue and red, the line S B = the amount of blue, and the line S R = the amount of red required to form white. Again, any point, say M, on the surface of the triangle, will represent a mixed color, the composition of which may be obtained by mixing the three fundamental colors in the proportions represented by the length of the lines M to green, M V, and M R. But the line V M passes on to the yellow Y; we may then replace the red and green by the yellow, in the proportion of the length of the line M Y, and mix it with violet in the proportion of S V. The same color would also be formed by mixing the amount M Y of yellow with M S of white, or by the amount R M of red with the amount M D of greenish blue.

(5.) *The Theory of Color-Perception.*—The theory generally accepted was first proposed by Thomas Young and afterwards revived by Helmholtz. It is based on the assumption that three kinds of nerve fibres exist in the retina, the excitation of which gives respectively sensations of red, green, and violet. These may be regarded as fundamental sensations. Homogeneous light excites all three, but with different intensities according to the length of the wave. Thus long waves will excite most strongly fibres sensitive to red, medium waves those sensitive to green, and short waves those sensitive to violet. Fig. 22 shows graphically the irritability of the three sets of fibres. Helmholtz thus applies the theory:—

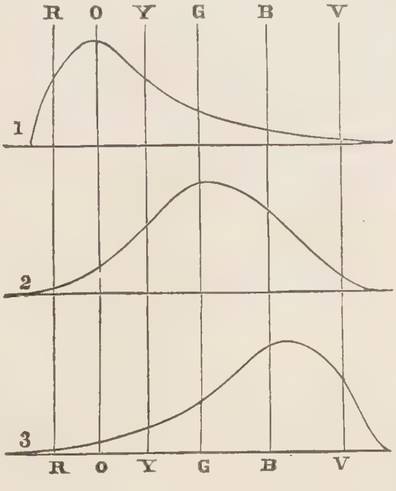

FIG. 22.—Diagram showing the irritability of the three kinds of retinal elements.

1. Red; 2. Green; 3. Violet. R, O, Y, G, B, V, initial letters of colors.

"1. Red excites strongly the fibres sensitive to red, and feebly the other two—sensation: *Red.*
2. Yellow excites moderately the fibres sensitive to red and green, feebly the violet—sensation: *Yellow.*
3. Green excites strongly the green, feebly the other two—sensation: *Green.*
4. Blue excites moderately the fibres sensitive to green and violet, and feebly the red—sensation: *Blue.*
5. Violet excites strongly the fibres sensitive to violet, and feebly the other two—sensation: *Violet.*
6. When the excitation is nearly equal for the three kinds of fibres, then the sensation is *White.*"

This theory explains some of the phenomena of what is called *color blindness* or *Daltonism.* All individuals appear to have some kind of color-sensation; in some, however, there may be no sensation for particular colors. The most common defect is insensibility to *red* (Daltonism properly so called). The spectrum to such an eye is deficient in red, and the sensation corresponding to all compound colors containing red is that of the complementary color only. Thus, white is bluish-green, and intense red appears green, so that red poppies in a green cornfield do not appear of a different hue from the green by which they are surrounded. If we suppose in such cases an absence or paralysis of the red-fibres, the phenomena are accounted for. Blindness to green and violet is rare.

Young's theory also explains the appearance of the consecutive colored images already referred to.

Suppose, for example, that we look at a red object for a considerable time; the retinal elements sensitive to red become fatigued. Then (1) if the eye be kept in *darkness*, the fibres affected by red being fatigued do not act so as to give a sensation of red; those of green and of violet have been less excited, and this excitation is sufficient to give the sensation of pale greenish-blue; (2) if the eye be fixed on a *white* surface, the red fibres, being fatigued, are not excited by the red rays contained in the white light; on the contrary, the green and violet fibres are strongly excited, and the consequence is that we have an intense complementary image; (3) if we look at a *bluish-green* surface, the complementary of red, the effect will be to excite still more strongly the green and violet fibres, and consequently to have a still more intense complementary image; (4) if we regard a *red* surface, the primitive color, the red fibres are little affected in consequence of being fatigued, the green and violet fibres will be only feebly excited, and therefore only a very feeble complementary image will be seen; and, (5) if we look at a surface of a *different* color altogether, this color may combine with that of the consecutive image, and produce a mixed color; thus, on a yellow surface, we will see an image of an orange color.

(6.) *The Contrast of Colors.*—If we look at a small white, gray, or black object on a colored ground, the object appears to have the color complementary to the ground. Thus a circle of gray paper on a *red* ground appears to be of a greenish-blue color, whilst on a blue ground it will appear pink. This effect is heightened if we place over the paper a thin sheet of tissue paper; but it disappears at once if we place a black ring or border round the gray paper. Again, if we place two complementary colors side by side, both appear to be increased in intensity. Various theories have been advanced to explain these facts. Helmholtz is of opinion that the phenomena consist more in modifications in judgment than in modifications of sensation; Plateau, on the other hand, attempts to explain them by the theory of consecutive images.

5. The Movements of the Eye.

(1.) *General Statement.*—The globe of the eye has a *centre of rotation,* which is not exactly in the centre of the optic axis, but a little behind it. On this centre it may move round *axes of rotation,* of which there are three,—an antero-posterior, a vertical, and a transverse. In normal vision, the two eyes are always placed in such a manner as to be fixed on one point, called the *fixed point* or the *point of regard.* A line passing from the centre of rotation to the point of regard is called the *line of regard.* The two lines of regard form an angle at the point of regard, and the base is formed by a line passing from the one centre of rotation to the other. A plane passing through both lines of regard is called the *plane of regard.* With these definitions, we can now describe the movements of the eyeball, which are of three kinds. (1) *First position.*—The head is erect, and the line of regard is directed towards the distant horizon. (2) *Second position.*—This indicates all the movements round the transverse and horizontal axes. When the eye rotates round the first, the line of regard is displaced above or below, and makes with a line indicating its former position an angle termed by Helmholtz the angle of vertical displacement, or the *ascensional angle;* and when it rotates round the vertical axis, the line of regard is displaced from side to side, forming with the median plane of the eye an angle called the *angle of lateral displacement.* (3) *Third order of positions.*—This includes all those which the globe may assume in performing a rotatory movement along with lateral or vertical displacements. This movement of rotation is measured by the angle which the plane of regard makes with the transverse plane, an angle termed the *angle of rotation* or of *torsion.*

The two eyes move together as a system, so that we direct the two lines of regard to the same point in space.

The eyeball is moved by six muscles, which are described in the article Anatomy, vol. i. p. 782. The relative attachments and the axes of rotation are shown in fig. 23. The following table, given by Beaunis, summarizes their action:—

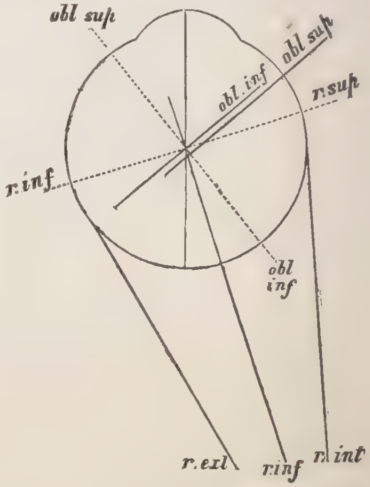

Fig. 23.—Diagram of the attachments of the muscles of the eye and of their axis of rotation, the latter being shown by dotted lines. (Fick.)

The axis of rotation of the rectus internus and externus being vertical, that is, perpendicular to the plane of the paper, cannot be shown.

Number of Muscles in activity.	Direction of Line of Regard.	Muscles acting.
One	Inwards	Internal rectus.
	Outwards	External rectus.
Two	Upwards	Superior rectus. Inferior oblique.
	Downwards	Inferior rectus. Superior oblique.
Three	Inwards and upwards.	Internal rectus. Superior rectus. Inferior oblique.
	Inwards and downwards.	Internal rectus. Inferior rectus. Superior oblique.
	Outwards and upwards.	External rectus. Superior rectus. Inferior oblique.
	Outwards and downwards.	External rectus. Inferior rectus. Superior oblique.

The term *visual field* is given to the area intercepted by the extreme visual lines which pass through the centre of the pupil, the amount of dilatation of which determines its size. It follows the movements of the eye, and is displaced with it. Each point in the visual field has a corresponding point on the retina, but the portion, as already explained, which secures our attention is that falling on the yellow spot.

(2.) *Simple Vision with Two Eyes.*—When we look at an object with both eyes, having the optic axes parallel, its image falls upon the two yellow spots, and it is seen as one object. If, however, we displace one eyeball by pressing it with the finger, then the image in the displaced eye does not fall on the yellow spot, and we see two objects, one of them being less distinct than the other. It is not necessary, however, in order to see a single object with two eyes that the two images fall on the two yellow spots; an object is always single if its image fall on *corresponding points* in the two eyes. Thus, in the experiment above described, after having seen two images by displacing one eyeball, we may be able again to

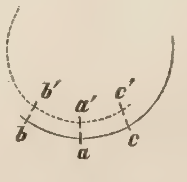

Fig. 24.—Diagram to illustrate the physiological relations of the two retinæ.

see only one image by pressing on the other eyeball. There are then corresponding points in the two retinæ, so that if they were superposed the two yellow spots would coincide; the upper and lower parts of the left retina would touch the upper and lower parts of the right retina; the nasal side of the left retina would correspond to the temporal side of the right retina, and the reverse would also hold good. The relation of the two retinæ to each other in the field of vision may be illustrated by the diagram in fig. 24. When an image falls on non-corresponding points of the retina, it is seen double.

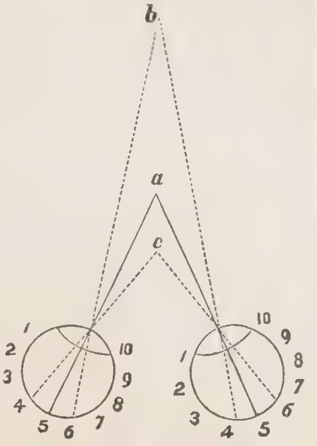

Fig. 25.—Diagram to illustrate phenomena of double vision. (Müller.)

Thus, as in fig. 25, suppose two eyes looking at a single object, placed at *a* *b* or *c*. If the image of the point *b* fall in one eye on 6 and in the other on 7, the point 6 of the one retina being correspondent with the point 6 of the other retina, the distance of the two images seen will be equal to the distance between 6 and 7. Again, if images of *a* fall on 5 and 5, it will be seen single. Further, if the image of *b* fall on the left eye at 6 and on the right at 4, as these two points do not correspond, it will appear double. And so with regard to the other retinal points indicated by the numbers. The phenomena may also be studied with the aid of fig. 26. Any object at a'', or at b'', or at c'', will be seen simply by the two eyes A and B, as the images fall on corresponding points in the retinæ, namely, aa', bb', and cc'. It will be readily seen that, if the eye B were displaced, the images would not fall on corresponding points, and consequently two would be seen.

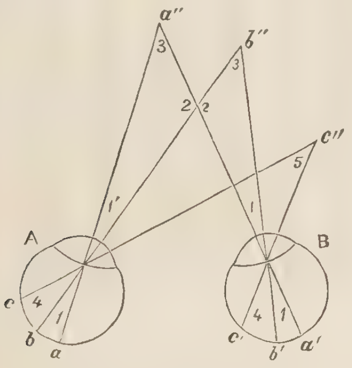

Fig. 26.—Diagram to illustrate the theory of corresponding retinal points. (Müller.)

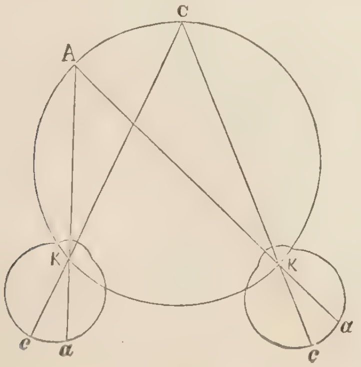

Fig. 27.—Diagram to illustrate the simple horopter.

The name *horopter* has been given to a line connecting those points in the visual field which form their image on corresponding points of the retina. The older physiologists first gave this name to "a straight line or plane, passing through the point of convergence of the axes of the eyes or the point to which the eyes are directed;" but Vieth and Müller showed that it cannot be a straight line or plane, but must have a circular form.

Thus if the points *a*, *b*, *c* in fig. 26 correspond to the points a', b', c', the angles 4 and 1 in the one eye must correspond to the angles 4 and 1 in the other. Then *a* *b* being equal to a' b', the angle 1 in eye A equal to angle 1 in eye B, the angles 1' and 1' will be equal. Since the angles 2 and 2 are equal, the angles 3 and 3 must also be equal. In the same way, the angle 5 is equal to angle 3. For $b\ c = b'\ c'$, and angle 4 = angle 4. Thus the angles 3, 3, and 5 are equal, and a'' b'' c'' cannot lie in a straight line, for it is the property of a circle only that angles erected on the same chord, and reaching the periphery have at the periphery equal angles. (Müller's *Physiology*, vol. ii. p. 1195.) A line joining a'', b'', and c'' is therefore the simple horopter, and its form is illustrated by fig. 27. It is a circle, of which the chord is formed by the distance between the points of decussation of the rays of light in the eye (K A C K in fig. 27). Its size is determined by the position of the two eyes, and the point toward which their axes converge. This is illustrated by fig. 28. Thus if *a* *b* be the distance of the eyes from each other, the circle *c* is the horopter for the object marked 1, the circle *d* for 2, and the circle *e* for 3.

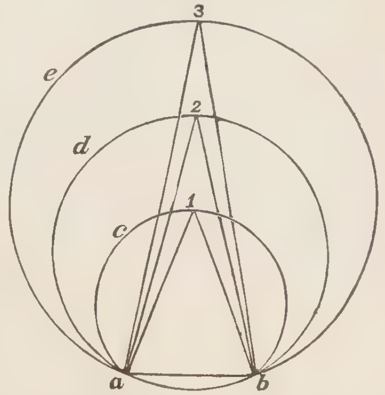

Fig. 28.—Diagram illustrating the simple horopter of objects at different distances from the eyes.

An object which is not found in the horopter, or, in other words, does not form an image on corresponding points of the retinæ, is seen double. When the eyeballs are so acted upon by their muscles as to secure images on non-corresponding points, and consequently double vision, the condition is termed *strabismus*, or squinting, of which there are several varieties treated of in works on ophthalmic surgery. It is important to observe that not only the correctness of the theory of corresponding points of the retina, but also that there are corresponding points in the brain, at the central ends of the optic fibres. Such fusion of images may occur without consciousness,—at all events, it is possible to imagine that the cerebral effect (except as regards consciousness) would be the same when a single object was placed before the two eyes, in the proper position, whether the individual were conscious or not. On the other hand, as we are habitually conscious of a single image, there is a psychical tendency to fuse double images when they are not too dissimilar.

(3.) *Binocular Perception of Color.*—This may be studied as follows. Take two No. 3 eye-pieces of a Hartnack's microscope, or two eye-pieces of the same optical value from any microscope, place one in front of each eye, direct them to a clear window in daylight, keep them parallel, and two luminous fields will be seen, one corresponding to each eye. Then converge the two eye-pieces, until the two luminous circles cross, and the central part, like a bi-couvex lens, will appear clear and bright, while the outer segments will be much less intense, and may appear even of a dim gray color. Here, evidently, the sensation is due to a fusion of impressions in the brain. With a similar arrangement, blue light may be admitted by the one eye-piece and red by the other, and on the convergence of the two, a resultant color, purple, will be observed. This may be termed the binocular vision of colors. It is remarkable that by a mental effort this sensation of a compound color may be decomposed into its constituents, so that one eye will again see blue and the other red.

6. THE PSYCHICAL RELATIONS OF VISUAL PERCEPTIONS.

(1.) *General Characters of Visual Perceptions.*—All visual perceptions, if they last for a sufficient length of time, appear to be external to ourselves, erect, localized in a position in space, and more or less continuous.

(*a*) *Visual Sensations are referred to the Exterior.*—This appears to be due, to a large extent, to habit. Those who have been born blind, on obtaining eyesight by an operation, have imagined objects to be in close proximity to the eye, and have not had the distinct sense of exteriority which most individuals possess. Slowly, and by a process of education, in which the sense of touch played an important part, they gained the knowledge of the external relations of objects. Again, phosgenes, when first produced, appear to be in the eye, but when conscious of them, by an effort of imagination, we may transport them into space, although they never appear very far off.

(*b*) *Visual Sensations are referred to Erect Objects.*—Although the images of objects are *inverted* on the retina we see them erect. The explanation of the effect is that we are conscious, not of the image on the retina, but of the luminous object from which the rays proceed, and we refer the sensation in the *direction* of these rays. Again, in running the eye over the object, say a tall pole, from base to apex, we are not conscious of the different images on the retina, but of the muscular movements necessary to bring the parts successively on the yellow spot.

(*c*) *Visual Sensations are referred to a Position in Space.*—The localization of a luminous point in space can only be determined by observing its relations to other luminous points with a given position of the head and of the eye. For example, in a perfectly dark room, if we look at a single luminous point, we cannot fix its exact position in space, but we may get some information of a vague character by moving the head or the eye. If, however, a second luminous point appears in the darkness, we can tell whether it is nearer or farther distant, above or below the first. So with regard to other luminous points we observe their reciprocal relations, and thus we localize a number of visual impressions. There are three principal directions in space—(1) the *transverse* (breadth), the *vertical* (height), and the *sagittal* (depth). Luminous points may be localized either in the transverse or vertical directions. Here we have to do simply with localization on a surface. A number of points may be observed simultaneously (as when the eye is fixed) or successively (as when the eye moves). If the movement of the eye be made rapidly, the series of impressions from different points may be fused together, and we are conscious of a *line*, the direction of which is indicated chiefly by the muscular sensations felt in following it. The case is different as regards points in the sagittal direction. We see only a single point of this line at a time; it may be a transverse series of retinal elements A, B, and each of these formed by a number of smaller elements 1, 2, 3, 4 situated in the axis of each principal element; it may be, on the other hand, the transverse line *a b* situated in space and formed by a series of points in juxtaposition. Each of these points will impress a retinal element, and the result will be the perception of a transverse line; but this will not be the same for the points *c, d, e. f, g,* situated in space in a linear series, in the sagittal direction; only one of those points *c* will impress the corresponding retinal element, and we can see only *one* point at a time in the line *c g*. By accommodating successively, however, for the various points at different and considerable distances along the line *c g*, we may excite retinal elements in rapid succession. Thus, partly by the fusion of the successive impressions on the retina, and partly from the muscular sensations caused by repeated accommodations and possibly of ocular movements, we obtain a notion of *depth* in space, even with the use of only one eye. It is, however, one of the chief effects of binocular vision to give precision to the notion of space in the sagittal direction.

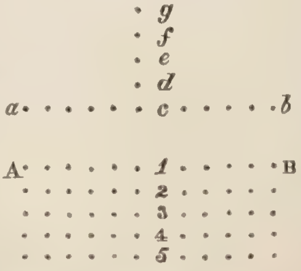

FIG. 29.—Diagram illustrating the localization of visual perceptions.

FIG. 30.—Diagram to illustrate illusions of size and distance.

(*d*) *Visual Sensations are continuous.*—Suppose the image of a luminous line falls on the retina, it will appear as a line although it is placed on perhaps 200 cones or rods, each of which may be separately excited, so as to cause a *distinct* sensation. Again, on the same principle, the impression of a superficial surface may be regarded as a kind of *mosaic*, made up of individual portions corresponding to the rods or cones on which the image of the surface falls. But in both cases, the sensation is continuous, so that we see a line or a surface. The individual images are fused together.

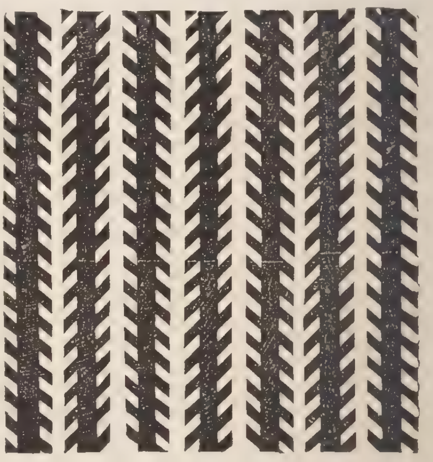

FIG. 31.—Zoellner's figure showing an illusion of direction.

(2.) *Notions derived from Visual Perceptions.*—When we look at any object, we judge of its size, the direction of its surfaces (unless it be a point), its distance from the eye, its apparent movement or fixedness, and its appearance of solidity.

(*a*) *Apparent Size.*—This, so far as regards a comparatively small object, depends on the size of the retinal image, as determined by the visual angle. With a very large object, there is an appreciation of size from the muscular sensations derived from the movements of the eyeball, as we "range" the eye over it. It is difficult to appreciate the distance separating two points between which there are other points, as contrasted with an apparently similar distance without intermediate points. For example, the distance A to B appears to be greater than from B to C, in fig. 30.

(*b*) *Direction.*—As the retina is a curved surface, a long straight line, especially when seen from a distance, appears curved. In fig. 31 a curious illusion of direction, first shown by Zoellner, is depicted. If these lines be looked at somewhat obliquely, say from one corner, they will appear to converge or diverge, and the oblique lines, on each side of the vertical lines, will appear not to be exactly opposite each other. But the vertical lines are parallel, and the oblique lines are continuous across them. The effect is evidently due to an error of judgment, as it may be controlled by an intense effort, when the lines will be seen as they really are.

(*c*) *Apparent Distance.*—We judge of distance, as regards large objects at a great distance from the eye—(1) from their apparent size, which depends on the dimensions of the visual angle, and (2) from the interposition of other objects between the eye and the distant object. Thus, at sea, we cannot form, without great experience, an accurate estimate of how many miles we are off the coast, and all know how difficult it is to estimate accurately the width of a river. But if objects be interposed between the eye and the distant object, say a few vessels at different distances at sea, or a boat in the river, then we have certain materials on which to form a judgment, the accuracy of which, however, even with these aids, will depend on experience. When we look at a near object, we judge of its distance chiefly by the sense of effort put forth in bringing the two lines of regard to converge upon it.

(*d*) *The Movement of a Body.*—If the eye be fixed, we judge of movement by successive portions of the retina being affected, and possibly also, by a feeling of an *absence* of muscular contractions necessary to move the eyeballs. When the eye moves, so as to "follow" the object, there is a sense of muscular effort, which is increased when, in addition, we require to move the head.

(*e*) *The Apparent Solidity of an Object.*—If we look at an object, say a cube, first with the right eye and then with the left, it will be found that the two images of the object are somewhat different, as in fig. 32. If, then, by means of a stereoscope, or by holding a card between the two eyes, and causing a slight convergence of the eyes, the two images are brought upon corresponding points of the two retinæ, the image will at once be seen in relief.

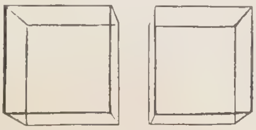

FIG. 32.—Illustrating stereoscopic vision.

Consult regarding the physiology of the eye, as the most complete treatise on the subject, Helmholtz's *Optique Physiologique*, 1867; one of the best of the older treatises is Mackenzie, *On the Eye and Vision*, 1841; in the first-mentioned treatise, a full list is given at the end of each section of all the more important works and monographs bearing on the physiology and optical arrangements of the eye, up to 1867. A very valuable bibliographical account is one recently published by J. Plateau, entitled *Bibliographie analytique des principaux phénomènes subjective de la Vision depuis les temps anciens jusqu'à la fin du XVIII^e siècle, suivie d'une bibliographie simple pour la partie écoulée du siècle actuel: extrait du tome xlii. des Mémoires de l'Académie royale des sciences, des lettres, et des beaux-arts de Belgique*, 1877. (J. G. M.)

EZEKIEL (יְחֶזְקֵאל *i.e*, יְחַזֵּק אֵל, God will strengthen, or יְחֱזַק אֵל, God will prevail; Ἰεζεκιήλ; *Ezechiel*) was the son of Buzi a priest, probably of the line of Zadok, who appears to have lived in Jerusalem, and to have held a position of some prominence there. According to an ancient and not impossible interpretation of his own words (chap. i. 1), Ezekiel was born in 624 B.C. This interpretation is at least preferable to that which reckons "the thirtieth year" from a hypothetical era of Nabopolassar; but it is not free from all objection, and if it fail us we have no data for precisely determining the prophet's age. Notwithstanding the expression made use of by Josephus (παῖς ὤν, *Ant.*, x. 7, 3) we may reasonably assume, however, that he had at least attained to early manhood, and already had read and observed much, when, along with King Jehoiachin and many other prisoners of the better class (2 Kings xxiv. 12–16; Jer. xxix. 1), he was carried into exile by Nebuchadnezzar in 599 B.C. With others of his compatriots he was settled at a place called Tel-Abib ("Cornhill"), on the banks of the river Chebar, by which most probably the Nahr-Malcha or "Grand" Canal of Nebuchadnezzar is meant, though some still think of the Chaboras (modern Khabur), an affluent of the Euphrates more to the north.[1] We are left almost wholly to precarious inference and conjecture for all further details of his history. We learn incidentally, indeed, from his writings that he was a married man living in a house of his own, and that his wife died in the ninth year of his exile. But of the nature of his ordinary employments, if he had any, we are not informed. His life, as a priest whose heart was thoroughly absorbed in priestly work, could hardly fail to be tinged with sadness, condemned as it was to be spent in an "unclean land" far away from "the inheritance of the Lord." He seems to have been of a brooding temperament, and to have passed much of his time in silence and solitude. A recent writer (in the *Studien u. Kritiken* for 1877) has ingeniously suggested and endeavored to show that he was an invalid, suffering much from some chronic nervous malady. In the fifth year of his exile (594 B.C.) he had a remarkable vision, of which he has given a very full description in the opening chapters of his book. On this occasion he was divinely called to the prophetic office. Thenceforward, for a period of at least 22 years, both orally and in writing, he continued to discharge prophetic functions at frequent if somewhat irregular interval; and whatever may have been the force and bitterness of the opposition he originally had to face, he ultimately, as a "watchman" and acknowledged leader of public opinion, came to exercise an incalculably powerful influence in keeping alive the Jewish national feeling, and also in quickening and purifying the religious hopes and aspirations of his time. The last date mentioned in his writings is the 27th year of his exile (572 B.C.). It is not probable that he lived long after that time. Nothing authentic, however, has been handed down to us as to the time, place, or manner of his death. Several unimportant traditions may be found in the work of the Pseudo-Epiphanius, *De vit. et mort. proph.*, in the *Itinerary* of Benjamin of Tudela, and elsewhere.

In the present Massoretic canon the book of Ezekiel stands third in order among those of the so-called Nebî'îm Aharônîm (latter prophets), being preceded by those of Isaiah and Jeremiah, and followed by that of the twelve minor prophets. In the list of canonical books given in the Talmud (*Baba bathra*, 14, 2) it is the second of the four, being followed by "Isaiah" and "the twelve." Its arrangement is unusually simple, the chronological corresponding for the most part with the natural order. Its three divisions date respectively from before, during, and after the siege of Jerusalem.

1. The first 24 chapters carry the reader from the time of the prophet's consecration down to the beginning of the siege of Jerusalem, *i.e.*, from 594 to 590 B.C. They are made up of some 29 distinct oracles, all of which, with the trifling exception of xxi. 33–37 [28–32], have direct reference to the religious and political condition of Ezekiel's compatriots in Babylonia and in Palestine. First in order stands the famous "chariot" (comp. 1 Ch. xxviii. 18) vision, which has been so variously estimated, both from the æsthetic and from the theological point of view by different critics. Rightly interpreted, as a mere description, it cannot justly be called vague or obscure, and it is hard to account for the strange stories told of the difficulties felt by the Jews in expounding it. The prophet sees in a storm-cloud coming out of the north a group of four living creatures (cherubs), each with four wings and four different faces. Together they are borne upon four wheels which are full of eyes. Resting upon their heads is a firmament, supporting a sapphire throne, whereon is seated a man-like figure, which is almost hidden in a blaze of light. Hereupon Ezekiel receives and eats the bitter-sweet roll in which are written "lamentations and mourning and woe;" he is now ready to go forth to his fellow-countrymen fearlessly declaring the truth as it is revealed to him, however unwelcome it may be. The recorded oracles that follow belong to the fifth, sixth, seventh, and ninth years of his exile. They can be understood only when viewed in connection with the general history of that period. Soon after his accession to the throne, Zedekiah, the uncle and successor of Jehoiachin, had begun to intrigue against his suzerain the king of Babylon, and had entered into secret relations with the king of Egypt. Ezekiel, like his older contemporary Jeremiah, had insight and sagacity enough to see the unwisdom of such a policy. By various symbolical actions (iv. 1–8; iv. 9–17; v. 1–4; vi. 11; xii. 1–16; xxi. 11 [6]), and also by unequivocal words, he repeatedly declared the certainty of the doom that was impending over Jerusalem, Judah, and all the mountains of Israel; he insisted on the uselessness of any struggle against Babylon, and distinctly predicted Zedekiah's captivity, blindness, and death. In language of the severest invective he rebuked the sins and idolatries, worse than those of Sodom, which had brought this inevitable ruin upon the land and

---

[1] Bleek (*Einl.* § 221, note) is probably wrong in identifying both כְּבָר and Chaboras with the חָבוֹר of 2 Kings xvii. 6, which is most probably the Khabur, a tributary of the Tigris (Delitzsch, *Jesaja*, p. 16, note).

people of the Lord; at the same time he held forth the hope of ultimate restoration and final happiness for both Judah and Ephraim at the end of "forty years," under the guidance of the coming prince "whose right it is" (chaps. xi. 14–21; xvii. 22–24; xx. 40–44; xxi. 32 [27]).

2. The eight chapters which follow (xxv.–xxxii.) belong to the period which elapsed between the beginning of the siege and the announcement of the capture of Jerusalem; xxix. 17–21 is an exception, belonging to the 27th year of the prophet's exile, and perhaps also chap. xxv., which has no date. During this period the prophet had no word to speak concerning Judah and Israel.[1] In these chapters the divine woe is pronounced against the seven neighboring nations which had shown most hostility to Judah and Israel, namely, Ammon, Moab, Edom, Philistia, Tyre, Sidon, and Egypt. The oracles relating to Tyre and Egypt are of great length. The others are comparatively brief. With regard to Tyre its capture and ruin by Nebuchadnezzar are foretold; and it is predicted that within a very short time Egypt shall be desolate forty years. The addition (xxix. 17–21) made seventeen years afterwards is apparently due to the fact that the earlier prediction regarding Tyre (xxvi. 7–14) had not been literally fulfilled. This section contains several passages that are specially interesting from a literary point of view. The description of the great merchant city in chap. xxvii. is noticeable for the richness of its details, and also for the vigor with which the comparison to a ship is carried out in ver. 5–9, 26–36. Striking also is the dirge (chap. xxviii. 12–19) upon the king: "Thou deftly-made signet-ring, full of wisdom, and perfect in beauty—thou hast been in Eden, the garden of God; every precious stone was thy covering, the sardius, the topaz, and the diamond. . . . Beside the overshadowing cherub did I place thee; thou wast upon the holy mountain of God; thou walkedst up and down in the midst of stones of fire. Thou wast perfect in thy ways from the day that thou wast created, till iniquity was found in thee. By the multitude of thy merchandise they have filled the midst of thee with violence, and thou hast sinned; therefore I will cast thee as profane out of the mountain of God, and the overshadowing cherub shall destroy thee from the midst of the stones of fire." As Tyre had been likened to a ship, so is Egypt with great minuteness of detail likened to a cedar in chap. xxxi. In chap. xxxii. follows a corresponding dirge, in which the assembled nations are represented as mourning women singing their lament over Egypt's grave.

3. The remainder of the book (xxxiii.–xlviii.) dates from after the fall of Jerusalem. In chap. xxxiii. we read how the prophet's dumbness was taken away in the twelfth (more propably the eleventh[2]) year of his exile, on the day when tidings were brought of the ruin of the city. Thereupon chap. xxxiv. opens with a brief retrospect, in which the former avarice, idleness, and cruelty of Israel's shepherds which have led to such disaster are exposed and rebuked. But the future—the immediate and the distant—chiefly occupies the prophet's mind. He tells of a coming shepherd, "David," under whose rule great and uninterrupted prosperity is to be secured. Edom is to be finally destroyed, but the twelve tribes are to be resuscitated and gathered together in their own land once more. A final battle has yet to be fought with Gog from the land of Magog, who shall come up against the chosen people with a great army, but only to be utterly destroyed, that Israel may thenceforward dwell in safety, wholly secure from any possible repetition of former calamities. Then follow in detail the final arrangements of the reorganized theocracy. The new temple, its dimensions, construction, furniture, are described; new laws as to sacrifice and festival are given for the priests, prince, and people of the new commonwealth. Directions are given for the equitable partition of the Holy Land among the twelve tribes, and for the building of the new city, which is to be called by the new name Jahveh Shammah, "the Lord is there." In all these regulations a general formal resemblance to the Pentateuchal legislation is abundantly manifest; but the differences of detail are no less striking. The following may be mentioned among others. Ezekiel's temple is larger, but simpler than that of Solomon. The distinction between the Holy and the Most Holy Place is much less marked. Both ark and high-priest are passed over in silence. The priesthood is specifically Zadokite. The "prince" has priestly functions assigned him. The morning burnt-offering is brought into special prominence; of the great festivals, the passover and the feast of tabernacles alone are noticed. The feast of pentecost is omitted, nor is any mention made of the great day of atonement, but an observance unknown in the Pentateuch, on the 1st and 7th of the first month, is proposed instead.

The genuineness of the book of Ezekiel has seldom been questioned. Some perplexity has been caused by the statement in the Talmud (*Baba bathra*, 15, 1) that the men of the great synagogue "wrote" Ezekiel. This obscure expression, by which most probably mere editing was meant, has been deprived of some of its importance by Kuenen's demonstration of the unhistorical character of the entire tradition regarding the great synagogue. Towards the close of last century some doubts were expressed by Oeder, Vogel, and an anonymous English writer in the *Monthly Magazine* (1798), with regard to the genuineness of the last nine chapters, which were supposed rather to be of a Samaritan origin, and by Corodi with respect also to chaps. xxxviii. and xxxix.; but these doubts were unanimously set aside by the not too conservative critics of that period. Zunz (*Gottesdienstliche Vorträge*, 1832; also *Gesammelte Schriften*, i. 217 *f.*, 1875) was the first to impugn the genuineness of the entire work, his thesis, in its most recent form, being that no such prophet as Ezekiel ever existed, and that the present work bearing that fictitious name was written somewhere between the years 440 and 400 B.C. His arguments are partly of the *a priori* kind, such as that the special predictions contained in it (xvii. 16, xxiv. 2, 16, etc.) are inconsistent with the genuineness of the book, and that it is inconceivable that in 570 B.C. any prophet could ever have thought of suggesting a new division of the Holy Land, or of drafting a new law-book, or of sketching the plans of a new temple and city. He argues further from the silence of other scriptures, particularly of Jeremiah and of the book of Ezra, with regard to Ezekiel; from certain allusions in the book itself, such as those to Daniel, to the wine of Halybon, etc.; also from its grammatical and linguistic peculiarities. There is still practical unanimity, nevertheless, among critics of all schools in the opinion that the stamp of Ezekiel's individuality is unmistakably and even obtrusively visible in every page of the book that bears his name. Keil and Kuenen agree in holding him to have been its author, and its editor as well. He is believed indeed not to have reduced it to its present form till near the close of his life; and many have embraced the opinion of Ewald, that the earlier dates have in some cases been incorrectly given by him. The text, it ought to be remembered, however, has reached us in a somewhat impure state.

The question principally discussed in recent years, and likely to be discussed for some time to come, in connection with Ezekiel's name is not whether he wrote less than tradition has assigned to him, but rather whether he may not possibly have written more. In connection with his theory of the late origin of the priestly legislation in the Pentateuch, Graf, in 1866, arguing from admitted similarities of style, gave it out as his belief that Ezekiel was the author of certain chapters of Leviticus (xviii.–xxiii., xxv., xxvi.). This view, which in substance has subsequently been adopted by Colenso and a few others, is manifestly one which does not admit of anything like demonstration. On the other hand, the larger and more interesting inquiry as to the relative priority of the Levitical and Deuteronomic legislations does not fall to be discussed in this place (see PENTATEUCH).

It remains that something should be said of Ezekiel's place as an author and as a religious teacher. His work may be judged from the purely literary point of view more fairly perhaps than that of any of the earlier prophets,—for unlike them, he was a writer much more than he was a preacher. His oracles were sometimes written before they were spoken; sometimes he wrote what he had no intention of speaking at all. He may be called one of the first sopherîm or scribes, if we use that word in its higher sense as denoting "bookmen," and not mere readers or copyists. As a leader of public opinion, he handled a variety of subjects in a corresponding variety of styles, but always with a manner entirely his own. His prose is invariably simple and unaffected; if there be any obscurity at all, it is really caused by his excessive desire to make it impossible for his reader to misunderstand him. His poetry has suffered much at the hands of translators, and the student who is wholly dependent on our Authorized Version will be often at a loss to understand the comparisons to Æschylus, Dante, or Milton which have occasionally been suggested. More than that of any other prophet, it has been subjected to the extremes of exaggerated praise and undue depreciation by its critics. The sympathetic modern reader, however, will be able to find in it a sublimity, a tenderness, a beauty, a melody, wholly peculiar to itself. Chapter xix., which even Schrader pronounces "masterly," may be specially referred to; also chapters xxviii. and xxxii.

---

[1] The language of xxiv. 27, taken along with that of xxxiii. 22, has led many to the conclusion that Ezekiel was literally dumb during this period, and that the oracles belonging to it must necessarily have been written, not spoken. But xxix. 21, dating from a much later period, requires to be also considered in this connection. He may possibly have been speechless on certain subjects only.

[2] So the Peshito and a few of the MSS. See Ewald, Hitzig, Bleek.

As a religious teacher, it is natural to compare Ezekiel with Jeremiah, his older contemporary, on the one hand, and with his immediate successor, the author of Isa. xl.–lxvi., on the other. It has frequently been said (most strongly perhaps by Duhm) that the contrast is very great, and very much to the disadvantage of Ezekiel. The three men, nevertheless, have much that is common to them all. If Ezekiel sometimes (and especially in his closing chapters) shows a preponderating externalism, a tendency to delight in the fulness and minuteness of his ceremonial details, it must not be forgotten that Jeremiah too looked forward to a restored sanctuary and a reorganized priesthood as essential elements in the perfected theocracy of the future. And if the "Great Unnamed" be justly regarded as one of the loftiest and purest exponents of the spiritual religion of coming days, we must at the same time remember that Ezekiel too had bidden men seek above all things that city, open only to the pure in heart, of which the glory is that "the Lord is there."

Ezekiel is nowhere mentioned by name in the New Testament, and the direct traces of his writings there, apart from those in the Apocalypse, are comparatively few. Matt. vii. 24–27 compared with Ezek. xiii. 10–13, and John x. 16 compared with Ezek. xxxiv. 22, 23, may be referred to. Both directly, however, and also through the writer of the Apocalypse, his influence upon Christian thought, and especially upon Christian eschatology, has been considerable.

Literature.—For the ancient, mediæval, and earlier modern commentaries, see Carpzow and other works of introduction. The most important works of recent date are those of Ewald, *Die Propheten des alten Bundes*, vol. ii. 2d ed., 1868, Engl. tr. 1877; Hävernick, *Commentar ü. d. Proph. Ezechiel*, 1843; Hitzig, *D. Proph. Ezechiel*, 1847; Fairbairn, *Exposition of the Book of Ezekiel*, 1851; Kliefoth, *D. Buch Ezechiels*, 1865; Hengstenberg, *D. Weissagungen d. Pr. Ezechiels*, 1867; Keil, *D. Prof. Ezechiel*, 1868; *The Speaker's Commentary*, vol. vi., 1876. See also Ewald's *Geschichte d. V. Isr.*, iv. 18 ff.; Kuenen, *Godsdienst van Israel*, vol. ii., and *Profeten en Profetie*, 1875, Eng. tr. 1877; Schrader's article "Ezekiel" in Schenkel's *Bibel-Lexicon;* Duhm, *Die Theologie der Propheten*, 1875. On the critical questions see Zunz, *Gottesdienstliche Vorträge*, pp. 157–299, and *Gesammelte Schriften*, 1875; Graf, *D. geschichtliche Bücher des A. B. 1866*; Keunen, in *Theol. Tijdschrift* for Sept., 1870; Colenso, *The Pentateuch aud Book of Joshua critically examined*, part vi., 1872; Klostermann on "Ezekiel" in the *Studien u. Kritiken* for 1877. The English reader may be referred to *The Holy Bible with various renderings and readings*, London, 1876. Bunsen's *Bibelwerk* will also be found useful by the ordinary reader of German. (J. S. BL.)

EZRA (עֶזְרָא, *i.e.*, help; Ἔσδρας; *Esdras*), the famous scribe, was a priest of the line of Zadok. According to the genealogy given in Ezra vii. 1–5, his father's name was Seraiah. If we identify this Seraiah with the person mentioned in Ezra ii. 2, Neh. xii. 1, then the Ezra who is the subject of the present article may well be identified, as has been done by Michaelis and others, with the Ezra named in the last-quoted texts; and in this case he must have been a very old man even at the beginning of that public work with which his name is chiefly associated. But a careful comparison of the genealogy in 1 Ch. vi. 4–15 with that in Ezra vii. leads rather to the conclusion that the latter has most probably been abridged, so far as the more immediate and less eminent ancestors of our Ezra are concerned. They are omitted probably because, though closely connected with Joshua, the son of Josadak, they did not avail themselves of the permission, granted by Cyrus, to return to Jerusalem in 536. They do not seem on that account, however, to have lost much, if any, of the social influence to which their high rank in the priesthood entitled them. Josephus tells us, somewhat mysteriously, that Ezra himself was high-priest of the Jews who were left in Babylon. Be this as it may, we know that when he first appears in history, in the seventh year of Artaxerxes Longimanus (458 B.C), he is already a man of great learning, zeal, and authority, enjoying the confidence, not only of his own compatriots, but also of the Persian king. It is to be regretted that we should so imperfectly know what was the true condition of the Jews in Babylon during the years that immediately followed the close of the "exile." We have various indications, however, that many of them devoted themselves to the study of the written law, kept up friendly intercourse with their compatriots in Jerusalem, regularly sent free-will offerings to the temple there (Philo, *Ad Caium*. 1013), and made occasional pilgrimages thither (Zech. vi. 9). In Judea, on the other hand, the fifty-eight years between 516 and 458, which are passed over in silence in the history, do not seem to have been more prosperous than the twenty preceding years of which the record has been preserved. Whether influenced by unfavorable reports of the condition of affairs at Jerusalem, or proceeding upon knowledge personally obtained in some previous visit, Ezra, who had "been directing his heart to seek the law of the Lord, and to do it, and to teach in Israel statutes and judgments," asked and received in the above-mentioned year the royal authority to make an official visit to Judea. From the terms of his commission, which are given in Ezra vii. 12–26, we learn that very considerable powers and privileges were at that time conferred upon him. On the first day of the first month of the Jewish year he set out on his westward journey, carrying with him many valuable offerings, and accompanied by some 1500 of his fellow-countrymen. The first considerable halt was made at "the river of Ahava," a locality which has not been identified as yet (it is called Theras in 1 Esdras viii. 41),[1] and here it was found that no Levites had joined the expedition. A message was accordingly sent to a place (now unknown) called Casiphia, where a large colony of them had settled, inviting their assistance. A considerable number of Levites were thus induced to join the party. A fast was thereafter appointed, the sacred treasures were solemnly entrusted to the keeping of twelve priests and twelve Levites (see Bertheau on Ezra viii. 24), and, deliberately dispensing with the usual military escort, the caravan set out on the twelfth day of the first month, arriving in Jerusalem on the first of the fifth. Here, in the course of the investigation which he had been commissioned to make, Ezra very soon found a field for his reforming activities. He learned that the population generally, priests, Levites, and rulers not excepted, had been intermarrying with the surrounding peoples to an extent which seemed to threaten the subversion of the true religion and the obliteration of the Jewish nationality. The unexpected discovery filled him with amazement and shame. Soon a large number of the inhabitants came to him, and, with Shechaniah for spokesman, assured him that the people at large were willing to dismiss their foreign wives with their children, if only he would take in hand the direction of the matter. With all convenient speed a solemn assembly of all Judah and Jerusalem was then convened, at which, after Ezra had pointed out to the people their transgressions, it was agreed, with only a few dissentient voices (Ezra x. 15, where for "were employed in" read "stood up against"), to appoint a committee to inquire into and decide on all the cases of mixed marriage. This committee had finished its work by the beginning of the following year, when a complete list was drawn up of those who had "taken strange wives" and now pledged themselves to put them away. Thus far the Scripture narrative has carried us; but at this point, after detailing the events of precisely one year of Ezra's public life, it abruptly breaks off; nor do we read of him again for the next thirteen years. Modern writers are by no means at one in the conjectures they make as to what occurred during the interval. Ewald thinks that he remained in Jerusalem during all the intervening time; others (such as Kuenen) are of the opinion that he very soon left the city, and that during his absence occurred those relapses and disasters which were the occasion of his subsequent activities, and also of those of Nehemiah. Hitzig thinks that he never reappeared at all, and corrects Nehemiah accordingly. According to the existing text, in the twentieth (twenty-first?) year of Artaxerxes, on the first day of the seventh month, we find him "in the open space that was before the watergate," solemnly reading, by public request, in the hearing of all the people, the "book of the law of Moses." One of the immediate effects of this fresh publication of the Mosaic law was that straightway the feast of tabernacles was observed as it had not been "since the days of Joshua the son of Nun;" and very soon afterwards a solemn fast was proclaimed, during which a written covenant was drawn up and confirmed by all the people, with Nehemiah at their head, by which they became bound "to walk in God's law which was given by Moses the servant of God," special prominence being given to the following points,—separation from the people of the land, strict observance of the sabbath day and the sabbatic year, punctual payment of the third part of a shekel for the service of the temple, of the first fruits for the priests, and of the tithes for the Levites. And now, once more, after a second period of public activity, which in this case seems to have lasted for little more than a month, the name of Ezra abruptly disappears from the Scripture narrative. We have no authentic information from any source as to the events of his subsequent life, or as to the time, place, and manner of his death. According to Josephus, "he died an old man, and was buried in a magnificent manner at Jerusalem;" but several palpable blunders with reference to Ezra in other parts of this historian's narrative warn us to be cautious in receiving this statement. Other traditions relate that he died in Babylon, or at Zamzumu on the Tigris, while on a journey from Jerusalem to Susa. According to the best texts of the Apocryphal work known to English readers as 2 Esdras, he did not die at all, but was translated (xiv. 49).

---

[1] Hit, anciently called Ihi or Ihi-da-Kira, "the well-known spot where caravans make their plunge into the desert," has been suggested. Stanley, *Lectures on Jewish Church*, iii. 116. See p. 587 of the present volume (art. EUPHRATES).

Tradition is somewhat inconsistent with itself also in the account it gives of Ezra's relation to the Pentateuch. At one time it speaks of him as a mere copyist or transcriber; at another time it speaks of him as a voluminous author, a prophet, an independent legislator. Modern criticism in like manner has not as yet reached an unanimous finding on the position occupied by him with reference to previous oral and written enactments. While Ewald, on the one hand, maintains that the last editor of the Pentateuch lived when the kingdom of Judah was still standing, Graf and Kuenen, on the other hand, assign to Ezra a very large share in the production of that law-book as we now have it. Between the two extremes there is room for an intermediate view, akin to that of ecclesiastical tradition, which, without determining the extent of Ezra's work, admits that, having before him an earlier work, he added and perhaps also altered some things in an editorial capacity.

It cannot be doubted that Ezra was successful in at least giving to the law as written a prominence and an influence which it had never before possessed. Under him it became the exclusive rule of public and private life in a way that had never before been known. The rise of the order of "scribes," that is, of those whose business it was to know the law, to interpret it, and "make a hedge" round it, can be traced directly to him. If he thus was in a sense the founder of that pharisaism which in later ages degenerated into the well-known forms which were so abhorrent to Christ, and to the spirit of Christianity, it ought to be remembered, on the other hand, that the synagogue services,—those assemblies throughout the towns and villages of the land in which the written word was weekly read and expounded with praise and prayer,—are most probably to be traced to his influence. The synagogue worship passed directly over from Judaism into the Christian church; and in this way Ezra, so far as he originated it, has exercised an incalculable influence on the religious culture of the race.

For much valuable information on the life and times of Ezra, and also for references to the older authorities, the histories of Israel by Ewald, Hitzig, Jost, Herzfeld, Graetz, and Kuenen may be consulted. See also Stanley's *Lectures on the History of the Jewish Church*, vol. iii. (J. S. BL.)

EZRA AND NEHEMIAH, BOOKS OF. The two canonical books entitled Ezra and Nehemiah in our English Bibles correspond to the 1 and 2 Esdras of the Vulgate, to the 2 Esdras and Nehemiah of the LXX., and to the Ezra and Nehemiah of the Massoretic text. Though for many centuries they have thus been treated as separate compositions, we have abundant evidence that they were anciently regarded as forming but one book. Thus, Origen (Euseb., *H. E.*, vi. 25), expressly enumerating the twenty-two books of the old covenant as acknowledged by the Jews and accepted by the Christian church, gives as one of them *Ἔσδρας πρῶτος καὶ δεύτερος ἐν ἑνὶ Ἐζρᾶ*. Melito of Sardis (Euseb., *H. E.*, iv. 26) in like manner mentions the book of Esdras only. So also the Talmud (in *Baba bathra*, 14, 2), nor can it be supposed that Josephus in his enumeration (*C. Ap.* i. 8) reckoned Nehemiah as apart from Ezra. Some of the oldest copies of the LXX. make no division between 2 Esdras and Nehemiah; and that the Massoretes themselves recognized no real separation is shown by their epicrisis on Nehemiah.

If the external evidence for the unity of the book of Ezra-Nehemiah is strong, the internal evidence is decisive. As the result of long-continued careful examination, modern criticism, with practical unanimity (Hävernick and Keil are hardly exceptions), has reached the conclusion that Ezra and Nehemiah, so far from being separate compositions, together constitute but a section of a larger historical work, the origin, authorship, and plan of which have already been discussed in the article CHRONICLES, to which the reader is referred. Comparatively little remains to be said here on the special questions that arise in connection with the Ezra-Nehemiah portion of the work.

Contents.—Resuming the abruptly broken off narrative of Chronicles, the first six chapters of Ezra relate how, in the first year of Cyrus king of Persia (537–6), Zerubbabel (called Sheshbazzar in chap. i.), along with Joshua and some 50,000 others who are enumerated according to their families, returned to Jerusalem, set up the altar of burnt-offering there, and in face of many difficulties and discouragements succeeded in rebuilding the temple, which was finally dedicated in the sixth year of Darius Hystaspis (516). An interval of fifty-eight years is then passed over in silence. The next chapters (Ezra vii.–x.) tell of Ezra's mission to Jerusalem in 458, and the dissolution of the heathen marriages there, the one result of a period of eight months' activity. Another blank of thirteen years occurs in the history. Then we read (Neh. i. 1–vii. 73*a*) of Nehemiah's expedition to Jerusalem, of the difficulties he encountered on his arrival there (445–4), and how, notwithstanding all the opposition of the Samaritans, the building of the walls was successfully completed in fifty-two days. The list of those who had returned under Zerubbabel is given as in Ezra, chap. ii. The narrative then goes on to relate (Neh. vii. 73*b*–x. 39) how in the same year the law of Moses was anew promulgated by Ezra, being solemnly read by him in the presence of a national assembly; how the feast of the tabernacles was then observed with a strictness that had been unknown since the days of Joshua the son of Nun; and how a written covenant was drawn up and signed by which the people pledged themselves to observe the whole law. After some genealogies and other lists have been given (Neh. xi.–xii. 26), we next have an account of the ceremonial which took place at the dedication of the walls (440); also further particulars of arrangements for due support of the temple-worship, and of steps taken for the exclusion of aliens from the congregation of Israel. Finally, after an interval of not less than twelve years, we read of a second visit of Nehemiah to Jerusalem (probably in 432). This visit was the occasion of renewed efforts towards religious and social reformation. Special mention is made of a collision with Eliashib the high-priest, and also with Joiada his son, which resulted in the expulsion of the latter.

Authorship.—The abstract given above shows very clearly that Ezra-Nehemiah cannot claim to be a continuous chronicle of all the important events of the 110 years of Jewish history over which it extends. Indeed, of the 110 years only some twenty are referred to at all. This want of continuity cannot be attributed to lack of materials; but rather to the specific purpose by which the author was guided in the selection of his facts. That purpose manifestly was to give an account of the progress of the restored theocracy in Judah and Jerusalem, particularly in what related to the temple, and to the share of the priests and Levites in the temple-worship. The striking literary peculiarities which are here displayed in all that is not merely copied from earlier documents, and even in the manner in which these documents themselves are handled, all indicate one and the same author for Chronicles and for Ezra-Nehemiah.

Sources.—It lies open to the most superficial observation that the work of the Chronicler is a compilation derived from many sources. The authorities for this portion of it may be classified as follows: (1) Statistics derived from official records. The list contained in Ezra ii., and repeated with some variations in Neh. vii., may be taken as a specimen. It was already old in Nehemiah's day (Neh. vii. 5). The author mentions also a book of chronicles (*dibrê hajjâmîm*, Neh. xii. 23), from which the information in Neh. xii. 1–26 was derived. Neh. xi. 3–36 and 1 Ch. ix. 3–33 are also probably drawn from a common source of an official character. (2) A history of the building of the temple and of the obstacles that had to be overcome, written in Chaldee. This history seems to have furnished the section Ezra v. 1–vi. 18, and also to have been the source of the document given in Ezra iv. 8–23. (3) Ezra's personal memoirs. These have been directly transcribed in Ezra vii. 27–ix. 15; and they have been drawn upon for Ezra vii. 1–11, for chap. x., and also for Neh. vii. 73*b*–x. (4) Nehemiah's personal memoirs. These have been extracted from in Neh. i. 1–vii. 5, xi. 1, 2, xii. 31–42, xiii. 4–30, and they have been combined with those of Ezra in Neh. vii. 73*b*–x.

Date.—In the article CHRONICLES it has been shown that the genealogies there given (1 Ch. iii. 19 *sq.*), when fairly interpreted, must be taken as reckoning the descendants of Zerubbabel to six generations, thus bringing the history down to near the close of the Persian monarchy. In Ezra-Nehemiah all the indications of date which are given go to support the same conclusion. Neh. xii. 11, 22 brings the list of high-priests down to Jaddua, the contemporary of Alexander the Great. In verse 22 there is a reference, moreover, to Darius Codomannus, the opponent of Alexander. The kings of Persia are throughout alluded to in a manner which is fitted to suggest that the Persian empire had already passed away. Ezra and Nehemiah themselves are occasionally spoken of, not as contemporaries, but as vanished heroes of the venerable past (see, for example, Neh. xii. 26, 47). But the same data which forbid us to fix a data for Ezra-Nehemiah earlier than 350 B.C., manifestly also forbid the conclusion of Spinoza (*Tract. Theol. Polit.*, x. 28) who placed the work later than the Maccabees.

Credibility.—The doubts raised by Graf and others with reference to the historical value of the earlier portion of the work of the Chronicler do not extend to the Ezra-Nehemiah section. There is general concurrence in the conviction that the sources he had access to fully guarantee the trustworthiness of his narrative. A question has, indeed, been raised as to the measure of sagacity he has shown in his employment of some of the materials he had at his disposal, Bertheau and others believing (in opposition to Ewald) that he has inappropriately introduced into the narrative of Ezra iv. certain documents which really refer to the later period of Nehemiah.

The text of Ezra-Nehemiah has reached us in a somewhat impure state. Great caution requires to be exercised, especially as regards the numerals and proper names. Some help may be got from the LXX. translator, who has been faithfully literal "almost to unintelligibility."

Literature.—In addition to the works referred to under CHRONICLES, the following may be consulted:—Zunz, *Gottesdienstliche Vorträge* (1832), p. 18 *sq.*; Bertheau's admirable commentary in the *Exegetisches Handbuch* (1862); his article "Chronik" in Schenkel's *Bibel-Lexicon*; Dillman on "Chronik" in Herzog's *Real-Encyclopädie*; Nägelsbach on "Ezra" in the same work; Keil, *Commentar* (Engl. tr. 1873); Schultz, in Lange's *Bibelwerk* (1876; Eng. tr. 1877); Rawlinson in the *Speaker's Commentary*, vol. iii. (J. S. BL.)

F.

F WAS the sixth letter of the primitive Greek alphabet. It represented the sound of our W, *i.e.*, a soft labial. But that sound was unpleasant to the Greek ear, and it began to fall out of use at an early time in all parts of Hellas; it disappeared most completely in the Ionic and in the cognate Attic dialect; it survived longer in the Æolic and the Doric, and it is not improbable that the symbol F may have been written in these dialects after the sound it represented had perished. The grammarians in dealing with this extinct letter gave it the name "digamma" from the shape of the symbol, *i.e.*, a gamma (Γ) with a second horizontal stroke, and they added the name "Æolic" from a mistaken impression that it lingered longer in that dialect than in the Doric. It was from the Doric of Cumæ, as has been already said (see ALPHABET), that the Latins derived the symbols of their alphabet, and F with the others. But though the Latin language contained the sound *w*, it did not seem necessary to have a special symbol to distinguish it from the vowel *u*; and F was used to express quite a different sound, one which the Greek did not possess. This was probably the same sound which the letter still denotes with us—the hard labio-dental (to which V is the corresponding soft sound) produced by pressing the upper teeth on the lower lip, and then letting the breath escape laterally or through the interstices of the teeth—very much, as Quintilian says in his amusing description of the Latin sound (xii. 10, 29), which "pæne non humana voce, vel omnino non voce, potius inter discrimina dentium efflanda est." It was quite distinct from *ph*—a distinction which we have sacrificed; *ph* was a *p* followed by a slight breath, not quite so strong as in "upheave," but very similar; and it expressed in Latin the sound of the Greek ϕ. The Greeks found the Latin *f* a difficult sound—much as the Germans find the English *th*—and we find Cicero laughing at a Greek witness because he could not pronounce the first letter of "Fundanius," which he doubtless called "P-hundanius." The emperor Claudius has the credit of endeavoring to improve the Roman system of spelling by filling up some of the defects of the alphabet. Thus, he proposed to use an inverted F (Ⅎ) to denote the corresponding soft consonant (V) which, as we have said above, had no special symbol in the Roman alphabet. Thus in inscriptions of his reign we find ℲOℲIMUS, IOℲI, etc. But this improvement did not long survive its author.

FABER, BASIL (1520–1576), a German schoolmaster and theologian, was born at Sorau in Lower Lusatia in 1520. After studying at the university of Wittenberg, which at that time was under the direction of Melanchthon, he chose the profession of a schoolmaster, and became rector of the school at Nordhausen, whence he went successively to Tennstädt, Magdeburg, and Quedlinburg. His religious opinions led to his being removed from his office in the last-named place in 1570, but a short time afterwards he received and accepted an invitation to become master of the Raths-gymnasium at Erfurt, where he continued till his death in 1576. Faber was a strong Lutheran, and translated the first 25 chapters of Luther's commentary on Genesis, and in various other ways zealously endeavored to promote the spread of Lutheran opinions. He was a contributor to the first four of the *Magdeburg Centuries.* He is, however, best known by his *Thesaurus Eruditionis Scholasticæ*, a work which for many years retained a high place in Germany as a scholastic manual. It was originally published in 1571, and the last edition, edited and improved by Leich, appeared in 1749.

FABER, CECILIA BÖHL VON (1797–1877), the great woman-novelist of Spain, better known by her masculine pseudonym of Fernan Caballero, was born at Morges, Canton de Vaud, in 1797, her parents being then on a tour through Switzerland. Her father, Johann Nikolas Böhl von Faber, the son of a Hamburg merchant, had removed early in life to Cadiz, prospered in business, professed the Catholic faith, and married Doña Francisca de Larrea, a member of the Spanish aristocracy. Cecilia received a considerable part of her education in Germany at Görslow near Schwerin, where her father had an estate; and here, besides other accomplishments, including a complete mastery of German and Spanish, she acquired a competent knowledge of Latin, English, French, and Italian. In 1813 she returned to Cadiz, and in the following year became the wife of Captain Planells, whom she accompanied to America, where she seems to have spent some years of married life. Not long after the death of her first husband, she was married to the Marques de Arco Hermoso, and in virtue of her exalted station frequently attended the court of Madrid, where she was much admired for her beauty, vivacity, and wit. In 1837, having, by the death of the marquis (1835), been again left a widow, she gave her hand to Señor de Arrom, a member of the bar. This union appears to have been productive of little happiness, and when her husband accepted an appointment as Spanish consul abroad, she decided to remain alone in Seville. It is to the trials and disappointments that came upon her in the later years of her life that the world is indebted for the fascinating works of this distinguished writer, who seems to have been driven to authorship less by any imperious literary instinct than by the necessity she felt for some anodyne against sorrow. Rarely does it happen that literary genius such as she possessed lies dormant for so long a time, unguessed by the world, hardly suspected even by its owner. As early as 1828, indeed, if not earlier, she had committed to writing, in the form of a novel, a tale of peasant life, which she had heard prosaically told under the olive trees at the village of Dos Hermanas, in the neighborhood of Seville, but singularly enough, she had preferred to make use of the German language, and does not appear to have contemplated publication. Although Washington Irving, in the course of one of his visits to Spain, had seen and praised the manuscript. and had encouraged the writer to cultivate literature, and especially Spanish literature, as a serious pursuit, it was not till many years afterwards that this first effort, *La Familia de Alvareda*, was presented to the public; nor was it till after her fiftieth year had been passed that she appeared as an author at all, and even then only under an assumed name. Her first, and in some respects her best, publication, *La Gaviota* (The Sea-Gull), was originally printed in short daily instalments in the pages of a Madrid newspaper in 1849. It met with high appreciation in the capital, and was accordingly followed at brief intervals by *Elia*, *Clemencia*, *La Familia de Alvareda*, *Una en Otra*, *Simon Verde*, and other *Cuadros de costumbres populares* (pictures of popular life). Slowly but surely the works of the new writer found their way all over the Peninsula, and gradually were translated into French and German, until within ten years she had achieved a European reputation. A collected edition of her works in 13 volumes was issued from the royal printing press at Madrid in 1859, and about the same time she received an appointment as governess to the royal children. From 1863 to 1868 she occupied rooms in the palace of the Alcazar,—the Hampton Court of Seville. At the revolution of 1868 she removed to private apartments in the Calle de Burgos; and though with advancing years her pen became less busy, she continued with unimpaired faculties to take a keen and kindly, if somewhat needlessly anxious, interest in the important events that were revolutionizing the institutions of her country. Among the numerous schemes of beneficence that busied her, especially in later life, was the promotion of a society for the prevention of cruelty to animals. She was engaged in correcting for the press the last sheets of a compilation of stories, nursery-rhymes, etc., for the use of children (*Cuentos, Oraciones, Adivinas, y Refranes populares è infantiles*) when she died in her eightieth year, on April 7, 1877.

Her works, though numbering about fifty in all, are none of them very large, and she cannot be called a voluminous writer. They all belong to one comparatively brief period of her long and chequered life; and, if classified at all, can be so only by the application of some comparatively artificial criterion. Some deal principally with the features of Andalusian life as it exists among the laborers and peasants; some delineate the higher phases of society; and in others "the interest lies, not in the characters of the persons and the description of scenery and manners, but in the selection of incidents which are intended to point a moral or adorn a proverb." While all are marked by deep and tender sympathy with nature, by subtle and unerring delineation of character, by a quaint humor that is never far removed from pathos, and by an exquisite power of expression, it may safely be said that, as "George Sand" is most delightful when she lovingly depicts the quiet scenes of Berri, the home of her youth, so Fernan Caballero excels in her descriptions of the peasant life of Andalucia. Foreign critics complain not unnaturally of the bitter ultramontane prejudice and the exaggerated *Españolismo* which are so needlessly paraded in almost all her works; yet even this peculiarity, as imparting to these productions of undoubted genius a unique *couleur locale*, may fairly enough be held to enhance rather than diminish their value in the eyes of the dispassionate student of the infinitely varied phases of human thought and feeling.

Besides those already noted, the following stories may be mentioned:—*Cuentos y Poesias populares Andaluces*, *Un Verano en Bornos*, *Cosa cumplida solo en la otra vida*, *La Estrella de Vandalia*, *Pobre Dolores*, etc. Her principal works may be found in the *Coleccion de Autores Españoles*, published by Brockhaus, Leipsic. Most of them have been translated into French. *La Gaviota* and *Elia* have been translated into English—the former by the Honorable Augusta Bethell (1867); *La Familia de Alvareda*, under the title of *The Castle and the Cottage in Spain*, by Lady Wallace, appeared in 1861, and a second translation, by the Viscount Pollington, was published in 1872. An appreciative and able estimate of Fernan Caballero, with a full analysis of several of her best known works, appeared in the *Edinburgh Review*, July, 1861.

FABER, FREDERICK WILLIAM (1814–1863), a famous hymn-writer and theologian, the son of Thomas Henry Faber, secretary to Dr. Barrington, bishop of Durham, was born on the 28th of June, 1814, at Calverley, Yorkshire, of which place his grandfather, Thomas Faber, was vicar. He attended the grammar-school of Bishop Auckland for a short time, but a large portion of his boyhood was spent in Westmoreland; and the lake scenery left an indelible impression on his imagination. He afterwards went to Harrow, where he remained until he became a student of Balliol College, Oxford, in 1833. About the beginning of 1835 he began to reside at University College, in consequence of obtaining a scholarship there; and in 1836 he gained the Newdigate prize for a poem on "The Knights of St. John," which elicited special praise from Keble. Among his college friends were Dean Stanley and Sir Roundell Palmer. In January, 1837, he was elected fellow of University College. Meanwhile he had given up the Calvinistic views of his youth, and had become an enthusiastic admirer and follower of John Henry Newman. In 1841 a travelling tutorship took him to the Continent; and, on his return, a book appeared called *Sights and Thoughts in Foreign Churches and among Foreign Peoples*, which he dedicated to his dear friend the poet Wordsworth. The journal of his travels is beautifully written, and reveals an intense love of nature, and an almost southern susceptibility to her charms. There is none of the interjectional piety which so often disfigures books of travel written by religious men. He accepted the rectory of Elton in Huntingdonshire, but soon after proceeded again to the Continent, with the intention of studying the methods followed by the Roman Catholic Church. Returning to Elton, he devoted himself, with great earnestness, to the work of his parish, although the two years he spent there were marked by severe mental struggles, which issued in his conversion to the Roman faith in November, 1845. On leaving Elton his parishioners sobbed out—"God bless you, Mr. Faber, wherever you go!" (*Life*, p. 238). He founded a religious community at Birmingham, called Wilfridians, after the name Wilfred, which Faber assumed. The community was ultimately merged in the oratory of St. Philip Neri, of which Father Newman was the head; and in 1849 a branch of the oratory—subsequently considered independent—was established in London, first in King William Street, and afterwards at Brompton, over which Father Faber presided till his death on the 26th of September, 1863. In spite of his weak health, an almost incredible amount of work was crowded into those years. He published a number of theological works, and edited the *Oratorian Lives of the Saints*. He was an eloquent preacher, a brilliant talker, and had an unsurpassed power of gaining the love of all with whom he came in contact. It is mainly as a hymn-writer, however, that he will be known in the future. There is a sweet saintliness, and at the same time a grandeur of thought and a simplicity of poetical expression, in Faber's hymns, which we fail to find in much of the Protestant hymnology. Among the finest are—"The Greatness of God," "The Will of God," "The Eternal Father," "The

God of my Childhood," "Jesus is God," "The Pilgrims of the Night," "The Land beyond the Sea," "Sweet Saviour! bless us ere we go," "I was wandering and weary," and "The Shadow of the Rock." The hymns are largely used in Protestant collections.

The only complete edition of Faber's *Hymns* is the one published by Richardson & Son in 1861, of which a second issue appeared in 1871. In addition to hymns, pamphlets, letters, and translations, he published the following works:—*Sights and Thoughts in Foreign Churches and among Foreign Peoples, All for Jesus, The Precious Blood, Bethlehem, The Blessed Sacrament, The Creator and the Creature, Growth in Holiness, Spiritual Conferences, The Foot of the Cross, Ethel's Book, Sir Lancelot, Poems, An Essay on Canonization and Beatification, Characteristics of the Lives of the Saints,* and *Catholic Home Missions. Notes on Doctrinal and Spiritual Subjects* were edited by Father Bowden, and issued after Faber's death See his *Life and Letters*, by Father Bowden, and *A Brief Sketch of the Early Life of the late F. W. Faber, D.D.*, by his only surviving brother.

FABER, George Stanley (1773–1854), an English clergyman, son of Thomas Faber, vicar of Calverley, Yorkshire, was born October 25, 1773. He entered University College, Oxford, in 1789, graduated B.A. in 1792, and in 1794 was elected fellow and tutor of Lincoln College. He received his M.A. degree in 1796, and his B.D. degree in 1803. In 1801 he was appointed to the office of proctor, and the same year he delivered the Bampton lecture, which he afterwards published under the title of *Horæ Mosaicæ*. He was at this time one of the foremost preachers of the university, and his earnestness and eloquence secured for his discourses an interested and eager audience. In his preaching he gave considerable prominence to the doctrines usually known as evangelical, but he endeavored to avoid as much as possible the technicalities of a system, and to give all that he spoke a directly practical bearing. Marrying in 1803, he lost his fellowship, and for two years he acted as curate to his father. In 1805 he became vicar of Stockton-on-Tees, and three years later of Redmarshall, both in the county of Durham. In 1811 he obtained the rectory of Long Newton, in 1831 was made a prebendary of Salisbury Cathedral, and the following year received the mastership of Sherborn Hospital, where he died in the master's residence on 27th January, 1854. Faber wrote over forty volumes treating more or less directly of theological subjects, and chiefly of those which are of a polemical nature. They manifest great and varied erudition, and considerable acuteness within a certain limited sphere; but his abilities are frequently misapplied in vain endeavors to establish baseless theories, and in minute discussions regarding subjects of no general or lasting importance.

Among his principal works are *Mysteries of the Cabiri, or the Great Gods of Phœnicia*, 2 vols., 1803; *Origin of Pagan Idolatry*, 3 vols., 1816; *Difficulties of Romanism*, 1826; *Apostolicity of Trinitarianism*, 2 vols., 1832; *Election*, 1842; *Papal Infallibility*, 1851; and the *Sacred Calendar of Prophecy*, 3 vols., 1828. The last is his most popular work, and has passed through several editions.

FABER, or Lefèvre, Jacobus (*c.* 1450–1536), surnamed Stapulensis, an eminent pioneer of the Protestant movement in France, was born of humble parentage at Étaples in Picardy about 1450, and received his higher education at the university of Paris. After having graduated, and for some time made use of the privilege of teaching which the degree of magister at that time actually conferred, he went to Italy for the prosecution of his favorite classical studies. On his return to Paris he became professor in the college of Cardinal Lemoine, and at the same time he began the publication, with introductions, commentaries, or translations, of various famous works, including the *Physics, Metaphysics,* and *Ethics* of Aristotle. In 1507 he commenced residence within the Benedictine Abbey of St. Germain des Près near Paris, of which his friend Briçonnet had become superior; and here he began to give himself to biblical studies. The first fruit of his labors was the *Quintuplex Psalterium; Gallicum, Romanum, Hebraicum, Vetus, Conciliatum* (Parisiis, Hen. Stephani, 1509). This was followed in 1512 by *S. Pauli Epistolæ XIV. ex vulgata Editione, adjecta intelligentia ex Græco cum commentariis*, a work characterized by great intelligence and independence of judgment. His *De Maria Magdalena et triduo Christi disceptatio*, published in 1517, provoked a violent controversy, and was ultimately condemned by the Sorbonne in 1521. In 1523 he removed to Meaux as vicar to his friend Briçonnet, who had recently been advanced to that bishopric; and in the same year he published his new French translation of the New Testament, also *Les Épistres et Évangiles pour les LII. dimanches de l'an à l'usage du diocèse de Meaux*. In his prefaces and notes to both these works he had expressly declared his conviction that the Bible is the only rule by which doctrines are to be tried, and also that justification is by faith alone. These utterances excited much hostility, but the powerful protection of the king (Francis I.) and of the Princess Margaret shielded him from any serious consequences. After the battle of Pavia (25th February, 1525), Francis being at the time in captivity, Faber was formally condemned, and his works were vigorously suppressed by a commission of the parliament; these proceedings, however, were at once quashed on the return of the king some months afterwards. In 1526 Faber became librarian in the royal palace at Blois; and two years afterwards his translation of the Pentateuch appeared. In 1530 he completed his translation of the Bible, which at once took a high place, has often been reprinted, and has indeed been the basis of all subsequent French versions, both Roman Catholic and Protestant. In 1531 he was induced by Margaret (who had become queen of Navarre) to take refuge at Nérac from the storm of persecution which had broken out with fresh violence; and here he spent the closing years of his life in comparative quietude. His death took place in 1536.

See Graf in *Zeitschr. f. histor. Theol.*, 1852, and in Herzog's *Real-Encyclopädie.* A full list of Faber's very numerous writings is given in the *Biographie Générale* (*s. v.* Lefèvre d'Étaples).

FABER, or Lefèvre, Johann (1478–1541), surnamed from the title of one of his works Malleus Hæreticorum, was the son of a smith named Heigerlin, and was born at Leutkirch in Swabia in 1478. At an early age he joined the Dominicans, and he afterwards studied theology at Freiburg in Breisgau, where he received the degrees of M.A. and doctor of canon law. His reputation for ability and learning soon led to his being appointed vicar of Lindau and Leutkirch, and shortly afterwards canon in the cathedral church of Basel. In 1518 the bishop of Constance named him one of his vicar generals, and Pope Leo X. appointed him to be papal protonotary. At this time Faber was on a friendly footing with the principal German Reformers, and sympathized generally with their opinions. Of the many evil customs with which the church had become infected, he was well aware, and he was so energetic in opposing the practice of indulgences in his diocese that he was looked upon with suspicion at Rome. He also defended Luther against the attacks of his opponent Eck, although he admitted that many of Luther's views were too far in advance of the times. In 1521, however, Faber made a journey to Rome, which seems to have wrought almost an immediate and complete change in his manner of regarding the efforts of the Reformers, for as soon as he returned he began strenuously to oppose them both by speech and writing. In 1523 he appeared as an opponent of Zwingli in a disputation at Zurich, and the same year he published his tractate against Luther entitled *Malleus Hæreticorum*. From this time his chief efforts were devoted either to win back the Reformers to the church of Rome, or to get that church to adopt such measures as would best tend to nullify their influence with the people. Among other means employed by him was the establishment of a boarding-house for poor theologians, in order to train a class of preachers fitted by their peculiar qualifications to rival the Reformed preachers in popular esteem. In 1526 Faber became court preacher to the emperor Ferdinand, and in 1527 and 1528 was sent by him as ambassador to Spain and England. He was chosen bishop of Vienna in 1531, and died there 12th June, 1541. Most of his works were directed against the doctrines of Protestantism. They were collected and published in 3 vols., Cologne, 1537, 1539, and 1541.

FABIAN GENS, The, was said by the genealogists to have been descended from Hercules and a daughter of the Arcadian Evander. Niebuhr's supposition of the Sabine origin of the clan has been held to be inconsistent with the tradition regarding the pre-Sabine institution of the *Lupercalia*, the yearly festival inaugurated at the sacrifice which

Romulus and Remus offered in the Lupercal after the death of Amulius, and at which, according to the legend, they agreed to distinguish their respective adherents by the names Quinctilii and Fabii. The two colleges of the Luperci retained these designations long after the members of the two clans ceased to exercise exclusive control over the *sacra*. The chief family names of the Fabian gens or clan, during the commonwealth, were Vibulanus, Ambustus, Maximus, Buteo, Pictor, Dorso, Labeo; and Verrucosus, Rullianus, Gurges, Eburnus, Æmilianus, Allobrogicus, may be enumerated among their *agnomina*. Vibulanus and the two following names belonged, however, to the same family at different epochs, Q. Fabius Vibulanus, who was consul in 412 B.C., having been the first to assume the cognomen of Ambustus; while Rullianus, according to some accounts, changed the latter into Maximus, in 312 B.C.—his full name thus being Q. Fabius Maximus Rullianus. Of the Vibulani, first noticed about the year 486 B.C., the most distinguished were the three brothers, Quintus, Kæso, and Marcus, one or other of whom filled one of the two consulships from that date to 479. In that year the Fabii—to the number, it is said, of 306 patricians, exclusive of their nnmerous dependents—emigrated from Rome under the leadership of Kæso, who had just been consul for the third time, and settled on the banks of the Cremera, a few miles above Rome. Some accounts have attributed that secession to the opposition which the Fabian support of the plebs had aroused among the old patrician families. For two years the exiles or seceders continued to be the city's chief defence against the Veientes, until at last they were surprised by the latter, and cut off to a man. The only survivor of the gens was the son of Marcus, who had been left behind at Rome, and who thus became the ancestor of the succeeding Fabii. He was consul in 467 B.C., and a member of the second decemvirate in 450. When the Gauls captured Rome in 390 the pontifex maximus was a Fabius Ambustus. The most famous of this line—*i.e.*, supposing Rullianus to have been the first Maximus—was the father of Rullianus. He was thrice consul, and was dictator in 351 B.C. His son, Rullianus, called by Arnold the "Talbot of the 5th century of Rome," was master of the horse in 365 B.C. to Papirius Cursor, by whom he was degraded for having fought and beaten the Samnites contrary to orders. In 296, when consul for the sixth time, he defeated, at the great battle of Sentinum, the combined forces of the Etrurians, Umbrians, Samnites, and Gauls. But the greatest Roman who bore the name of Fabius—one of the most illustrious Romans of the republic—was Q. Fabius Maximus Verrucosus (see below). Of the later Fabii, Q. Fabius Maximus Æmilianus and Q. Fabius Maximus Allobrogicus were among the most distinguished. The former, a Fabius only by adoption, served in the last Macedonian war, 168 B.C., and was consul in Spain 145 B.C., when he conquered Viriathus. He was the pupil and the patron of the historian Polybius. The Fabius named Allobrogicus (after his victory over the Allobroges and their ally Bituitus, king of the Arverni) was consul in 121 B.C. The Fabian name is occasionally met with as late as the 2d century A.D.

Perhaps the most complete work on this family is the *Disputatio de Gente Fabia*, by G. N. Du Rieu, Leyden, 1856, where may also be found a list of previous writers on the same subject.

FABIUS MAXIMUS VERRUCOSUS, Quintus, also named *Cunctator* and *Ovicula*, was one of the most distinguished Romans of the republic,—the incarnation of all that a Roman meant by patriotism. It appears that he served his first consulship in Liguria, 233 B.C., that he was censor in 230, and consul for the second time in 228. In 218 he was sent to Carthage to inquire whether that state approved of Hannibal's conduct in attacking Saguntum. The answer proved unsatisfactory; and Fabius, assuming the haughty dignity of a Roman senator, and folding up his cloak so as to form a cavity, thus addressed the nobles of Carthage: "Hic vobis bellum et pacem portamus; utrum placet sumite." Being answered that he might give which he pleased, he indignantly exclaimed, "Then I give you war;" and the deputies returned to Rome to state the result of their mission. The disastrous campaign on the Trebia, and the defeat on the banks of the Thrasymene Lake, warned the Romans that their successful resistance to Hannibal, and even their existence, depended on the wisdom of the general to whom they entrusted their troops. So Fabius was named dictator in 217, and began his tactics of "masterly inactivity." Manœuvring among the hills, where Hannibal's horse were useless, he cut off his supplies, harassed him incessantly, did everything except fight. His steady adherence to this plan, in spite of all the misconceptions which his caution had aroused at Rome, evinced the moral strength of the man. He was suspected of an ambition for the prolongation of his command. Hannibal was one of the few men in Italy who understood him. Even Minucius, the master of the horse, ridiculed the proceedings of Fabius; and he seized the opportunity of the latter's absence at Rome to attack the enemy, and win a victory. This tended only more strongly to confirm the opponents of Fabius in their opinion, and the command was divided between Minucius and Fabius. The result was exactly such as might have been anticipated. Minucius engaged in battle with Hannibal, and his army was on the verge of ruin when the opportune arrival of Fabius changed the aspect of affairs. Minucius seems to have had the moral courage to confess his folly, and cheerfully to submit to the orders of Fabius. Fabius having retired at the end of the legal time of six months, the conduct of the war was entrusted to Æmilius, who followed the ex-dictator's plan, and Varro, who did not. "You must beware of Varro, as well as of Hannibal," said Fabius; and the warning was followed by the disaster of Cannæ. Fabius might have accused him; but it is narrated that the magnanimous Roman thanked his rival "because he had not despaired of the republic." After the defeat at Cannæ (216 B.C.) he was appointed to the command of the armies with Marcellus, "the sword," as Fabius himself was "the shield," of the republic. He laid siege to the important city of Capua; and when Hannibal marched towards Rome, threatening the city itself, Fabius remained firmly at his post. In 214 B.C. when consul for the fourth time, he captured Casilinum in Samnium. In his fifth consulship, 209, he took the city of Tarentum; and when it was proposed, towards the conclusion of the war, that Scipio should pass into Africa, Fabius was decidedly opposed to the scheme. He did not live to witness the final success of Scipio, having died at an advanced age, 203 B.C. In the previously named year he became *princeps senatus*, a dignity almost hereditary in the family of the Fabii Maximi.

FABIUS PICTOR, Quintus, the father of Roman history, was the grandson of the Fabius who, surnamed Pictor for his artistic skill, bequeathed that name to a family of the Fabian gens. In the interval between the first and second Punic wars we find him taking an active part in the subjugation of the Gauls in the north of Italy (225 B.C.); and after the battle of Cannæ (216), he was employed by the Romans to proceed to Delphi in order to consult the oracle of Apollo. The rude muse of Nævius had already celebrated in verse the glory acquired by the Roman arms in the first Punic war, and Ennius had clothed the annals of his adopted country in the language of poetry. But till the time of Fabius Pictor, no one had appeared to chronicle in simple prose the *res gestæ* of Rome and the Romans. The historian's materials consisted of the *Annales Maximi. Commentarii Consulares*, and similar records (see Fasti) of names, feasts, battles, prodigies, and the like, together with such chronicles as every great Roman family preserved of its own deeds; as also—what furnished the most valuable part of his work—his own experiences in the second Punic war. His *Annals*, as they were called, existed in the time of Pliny the Elder, but are now known only from a few fragments and allusions. According to Dionysius, they contained a description of the battle of Thrasymene, and Niebuhr even conjectures that Dion Cassius derived his knowledge of Roman constitutional history from Pictor's work. It seems certain, however, that Fabius wrote his *Annals* in Greek. Polybius expressly asserts this to be the fact; and Cicero's allusion to the Latin prose writer who lived between the time of Cato and that of Piso probably refers to Sergius Fabius Pictor.

See C. T. Crutwell's *History of Roman Literature*, London, 1877, Du Rieu's *Disputatio*, and especially Wagner's *History of Roman Literature*, 1873, translated from Teuffel's *Geschichte*, 1870.

FABLE. With certain restrictions, the necessity of which will be shown in the course of the article, we may accept the definition which Dr. Johnson proposes in his life of

Gay :—" A *fable* or *apologue* seems to be, in its genuine state, a narrative in which beings irrational, and sometimes inanimate (*abores locuuntur, non tantum feræ*), are, for the purpose of moral instruction, feigned to act and speak with human interests and passions." Before tracing the history of the fable we may compare it with its nearest congeners in literature, the myth, the allegory, and the parable. The myth, whether, as is most commonly the case, it has its origin in some physical phenomenon, or can be traced to mistaken metaphor or distorted history, or is merely a play of the imagination, is always the unconscious product of the race, never like the fable invented expressly for a moral or didactic purpose. A closer analogy to the fable is to be found in the literary myth, the artificial product of a later age, such, for instance, as the *Λιταί* of the *Iliad*, the Hesiodic legend of Pandora, or the story of Er in the *Republic* of Plato. Yet these allegorical myths are clearly distinguished from the fable, inasmuch as the story and the moral are intermingled throughout. Between the parable and the fable there is no clear line of distinction. Archbishop Trench insists on two essential differences,—first, that the parable teaches spiritual truths, whereas the fable never lifts itself above the earth, and secondly, that the parable never transgresses the actual order of nature. But, though the parables of the New Testament may well be set in a class by themselves, a comparative study of religious writings will show that the parable is one of the commonest forms of religious teaching, and that no hard or fast line can be drawn between moral and spiritual truths. The second difference we should regard as accidental, and it is not altogether borne out by facts.

Most writers on the history of the fable are content to trace its origin to Æsop or the *Panca Tantra* of the mythical Vishnu Sarman, and these are doubtless the oldest collections which have been preserved in writing; but though we possess no earlier record, we may, from its wide diffusion, regard it as a natural growth of the imagination, and one of the most primitive forms of literature. It springs from the universal need of men to express their thoughts by concrete images and emblems, and thus is strictly parallel to the use of metaphor in language. Even now fables are made every day, and a quick-witted race like the Arabs will invent fables at every turn as the readiest form of argument. To take a familiar illustration, the wise saws and modern instances of Sam Weller would only need a slight expansion to form a very respectable book of fables. Our most familiar proverbs are often fables in miniature.

With the fable, as we know it, the moral is indispensable. As La Fontaine puts it, an apologue is composed of two parts, one of which may be called the body, the other the soul. The body is the fable, the soul the morality. But if we revert to the earliest type we shall find that is no longer the case. In the primitive beast-fable, which is the direct progenitor of the Æsopian fable, the story is told simply for its own sake, and is as innocent of any moral as our fairy tales of Little Red Ridinghood and Jack and the Beanstalk. Thus, in a legend of the Flathead Indians, the Little Wolf found in cloudland his grandsires the Spiders with their grizzled hair and long crooked nails, and they spun balls of thread to let him down to earth; when he came down and found his wife the Speckled Duck, whom the Old Wolf had taken from him, she fled in confusion, and this is why she lives and dives alone to this very day. Such animal myths are as common in the New World as in the Old, and abound from Finland and Kamtchatka to the Hottentots and Australasians. From the story invented, as the one above quoted, to account for some peculiarity of the animal world, or told as a pure exercise of the imagination, just as a sailor spins a yarn about the sea-serpent, to the moral apologue the transition is easy; and that it has been effected by savages unaided by the example of higher races seems sufficiently proved by the tales quoted by E. B. Tylor (*Primitive Culture*, vol. i., p. 411). From the beast-fables of savages we come next to the Oriental apologues which are still extant in their original form. The East, the land of myth and legend, is the natural home of the fable, and Hindustan was the birth-place, if not of the original, of these tales, at least of the oldest shape in which they still exist. The *Panca Tantra*, or fables of the Brahma Vishnu Sarman, have been translated into almost every language and adapted by most modern fabulists. The *Kalila wa Damna* (names of two jackals), or fables of Bidpai, is an Arab version made about 760 A.D. From the Hebrew version of Rabbi Joel, John of Capua produced a Latin translation about the end of the 15th century, whence all later imitations are derived. (See Monier Williams, *Indian Wisdom*, p. 508.) The *Hitopadesa*, or "friendly instruction," is a modernized form of the same work, and of it there are three translations into English—by Dr. Charles Wilkins, Sir William Jones, and Professor F. Johnson. The *Hitopadesa* is a complete chaplet of fables loosely strung together, but connected so as to form something of a continuous story, with moral reflections freely interspersed purporting to be written for the instruction of some dissolute young princes. Thus, in the first fable a flock of pigeons see the grains of rice which a fowler has scattered, and are about to descend on them, when the king of the pigeons warns them by telling the fable of a traveller who being greedy of a bracelet was devoured by a tiger. They neglect his warning and are caught in the net, but are afterwards delivered by the king of the mice, who tells the story of the Deer, the Jackal, and the Crow, to show that no real friendship can exist between the strong and the weak, the beast of prey and his quarry, and so on to the end of the volume. Another book of Eastern fables is well worthy of notice, *Buddhaghosha's Parables*, a commentary on the *Dhammapada, or Buddha's Paths of Virtue*. The original is in Pali, but an English translation of the Burmese version has been made by Captain T. Rogers, R. E. As the work is little known we may venture to extract a single gem. A young mother, disconsolate for the death of her first-born son, carries the dead body of her child from house to house seeking medicine to restore it. At last she is sent to Para Takem, the lord and master of the Buddhists, who promises to help her, but she must herself fetch the medicine, which is some mustard seed taken from a house where no son, husband, parent, or slave has died. Gladly the girl speeds on her errand, carrying the dead body of her son on her hip. By degrees she is taught that she is not the only mourner. In the whole of the Savetthi country everywhere children are dying, parents are dying. She leaves her dead son and returns to Para Takem, having learnt the first and last commandment of the Buddhist creed.

From Hindustan the Sanskrit fables passed to China, Thibet, and Persia; and they must have reached Greece at an early age, for many of the fables which passed under the name of Æsop are identical with those of the East. Æsop to us is little more than a name, though, if we may trust a passing notice in Hĕrodotus (ii. 134), he must have lived in the 6th century B.C. Probably his fables were never written down, though several are ascribed to him by Xenophon, Aristotle, Plutarch, and other Greek writers, and Plato represents Socrates as beguiling his last days by versifying such as he remembered. Aristophanes alludes to them as merry tales, and Plato, while excluding the poets from his ideal republic, admits Æsop as a moral teacher. Of the various versions of *Æsop's Fables*, by far the most trustworthy is that of Babrius or Babrias, a Greek of the 1st century A.D., who rendered them in choliambic verse. These, which were long known in fragments only, were recovered in a MS. found by M. Minas in a monastery on Mount Athos in 1842, and have been edited by Sir G. C. Lewis.[1] An inferior version of the same in Latin iambics was made by Phædrus, a slave of Thracian origin, brought to Rome in the time of Augustus, and manumitted by him, who tells us that he published in senarian verse the rude materials produced by Æsop; but the numerous allusions to contemporary events, as, for example, that to Sejanus in the Frogs and the Sun, which brought upon the author disgrace and imprisonment, show that many of them are original or free adaptations. For some time scholars doubted as to the genuineness of Phædrus's fables, but their doubts have been lately dispelled by a closer examination of the MSS. and by the discovery of two verses of a fable on a tomb at Apulum in Dacia. Phædrus's style is simple, clear, and brief, but dry and unpoetical; and, as Lessing has pointed out, he often falls into absurdities when he deserts his original. For instance, in Æsop the dog with the meat in his mouth sees his reflection in the water as he passes over a bridge; Phædrus makes him see it as he swims across the river.

To sum up the characteristics of the Æsopian fable, it is artless, simple, and transparent. It affects no graces of style, and we hardly need the moral with which each concludes, ὁ μῦθος δηλοῖ ὅτι, κ. τ. λ. The moral inculcated is that of worldly wisdom and reasonable self-interest. Æsop is no maker of phrases, but an orator who wishes to gain some point or induce some course of action. It is the Æsopian type that Aristotle has in view when he treats of the fable as a branch of rhetoric, not of poetry.

---

[1] M. Minas professed to have discovered under the same circumstances another collection of ninety-four fables by Babrius. This second part was accepted by Sir G. C. Lewis, but J. Conington has conclusively proved that it is spurious, and probably a forgery. See article BABRIUS.

If we consider their striking gift of narrative and their love of moralizing, it is strange that the Romans should have produced no body of national fables. But, with the doubtful exception of Phædrus, we possess nothing but solitary fables, such as the famous apologue of Menenius Agrippa to the Plebs, and the exquisite Town Mouse and Country Mouse of Horace's *Satires*.

The fables of the rhetorician Aphthonius in Greek prose, and those in Latin elegiac verse attributed to Avianus or Avienus, make, in the history of the apologue, a sort of link between the classical and the dark ages. In that overflowing chaos which constitutes the literature of the Middle Ages, the fable reappears in several aspects. In a Latin dress, sometimes in prose, sometimes in regular verse, and sometimes in rhymed stanzas, it contributed, with other kinds of narratives, to make up the huge mass of stories which has been bequeathed to us by the monastic libraries. These served more uses than one. They were always easier reading, and were often held to be safer and more instructive reading also, than the difficult and slippery classics, for those monks who cared for reading at all, and were not learned enough for any pursuit deserving the name of study. For those who were a little more active-minded, they aided the *Gesta Romanorum* and other collections of fabliaux or short novels, in suggesting illustrations available for popular preaching. Among those mediæval fables in Latin, very little of originality is to be detected. The writers contented themselves with working up the old fables into new shapes, with rendering from prose into verse, or from verse into prose,—a species of attempts which had its merits in such hands as those of Babrius or Phædrus, but from which no fruit could be expected to be gathered in the convents. The few monks who could have performed such a task well aimed wisely at something higher. It might be enough to name, among the monkish fabulists, Vincent of Beauvais, a Dominican of the 12th century, in whose *Speculum Doctrinale* are a good many prose fables, more than half of them from Phædrus. About the end of the same century, too, a considerable number of fables, some of which have been printed, were compiled by an English Cistercian monk, Odo de Cerinton. Nor was this the only collection that arose in England.

As the modern languages became by degrees applicable to literary use, fables began to appear in them. A good many still exist in Norman French, of which may be noted the fables called those of Ysopet, and those composed by Marie de France, the authoress of the well-known fabliaux. Later, also, they were not wanting, though not numerous, in our own tongue. Chaucer has given us one, in his Nonne Preste's Tale, which is an expansion of the fable "Don Coc et don Werpil" of Marie of France; another is Lidgate's tale of the Churl and the Bird. But the course of the short and isolated fables through the Middle Ages is not here worth prosecuting.

Several of Odo's tales, like Chaucer's story, can be ultimately traced to a work, or series of works, for the sake of which chiefly the mediæval history of the apologue is interesting—the History of Reynard the Fox. This great beast-epic has been referred by Grimm as far back as the 10th century, and is known to us in three forms, each having independent episodes, but all woven upon a common basis. The Latin form is probably the earliest, and the poem *Reinardus et Ysengrinus* dates from the 10th or 11th century. Next come the German versions. The most ancient, that of a minnesinger Heinrich der Glichesaere (probably a Swabian), was analyzed and edited by Grimm in 1840. In 1498 appeared *Reynke de Voss*, almost a literal version in Low Saxon of the Flemish poem of the 12th century, *Reinaert de Vos*. Hence the well-known version of Goethe into modern German hexameters was taken. It was written in 1793, during the siege of Mainz, and the philosophic poet sought, in the study of animal nature and passions, to divert his thoughts from the bloody scenes of the Reign of Terror. The poem has been well named "an unholy world bible." In it the Æsopian fable received a development which was in several respects quite original. We have here no short and unconnected stories. Materials, partly borrowed from older apologues, but in a much greater proportion new, are worked up into one long and systematic tale, so as to form what has been quaintly called an animal-romance. The moral, so prominent in the fable proper, shrinks so far into the back-ground that the work might be considered as a mere allegory. Indeed, while the suspicion of its having contained personal satires has been convincingly set aside, some writers deny even the design to represent human conduct at all; and we can scarcely get nearer to its signification than by regarding it as being, in a general way, what Carlyle has called "a parody of human life." It represents a contest maintained successfully, by selfish craft and audacity, against enemies of all sorts, in a half-barbarous and ill-organized society. With his weakest foes, like Chaunteclere the Cock, Reynard uses brute-force; over the weak who are protected, like Kiward the Hare and Belin the Ram, he is victorious by uniting violence with cunning; Bruin, the dull, strong, formidable Bear, is humbled by having greater power than his own enlisted against him; and the most dangerous of all the fox's enemies, Isengrim, the obstinate, greedy, and implacable Wolf, after being baffled by repeated strokes of malicious ingenuity, forces Reynard to a single combat, but even thus is not a match for his dexterous adversary. The knavish fox has allies worthy of him in Grimbart the watchful badger, and in his own aunt Dame Rukenawe, the learned She-ape; and he plays at his pleasure on the simple credulity of the Lion-King, the image of an impotent feudal sovereign. The characters of these and other brutes are kept up with a rude kind of consistency, which gives them great liveliness; many of the incidents are devised with much force of humor; and the sly hits at the weak points of mediæval polity and manners and religion are incessant and palpable.

It is needless, as has already been said, to attempt tracing the appearance which fables, or incidents borrowed from them, make so frequently as incidental ornaments in the older literature of our own country and others. Nor is there here fit occasion for dwelling minutely on the cultivation of the apologue in modern times, as a special form of poetical composition. It has appeared in every modern nation of Europe, but has nowhere become very important, and has hardly ever exhibited much originality either of spirit or of manner. In our own language, Prior indicated the possession of much aptitude for it; but neither the fables of Moore, nor even the much more lively ones of Gay, possess any distinguished merit. To Dryden's spirited remodellings of old poems, romances, and fabliaux, the name of fables, which he was pleased to give them, is quite inapplicable. In German, Hagedorn and Gellert are quite forgotten; and even Lessing's fables are read by few but schoolboys. In Spanish, Yriarte's fables on literary subjects are sprightly and graceful. A spirited version of the best appeared in *Blackwood's Magazine*, 1839. Among Italians Pignotti is famous for versatility and command of rhythm, as amongst Russians is Kriloff for his keen satire on Russian society. He has been translated into English by Mr. Ralston.

France alone in modern times has attained any pre-eminence in the fable, and this distinction is almost entirely owing to one author. Marie de France in the 13th century, Gilles Corrozet, Guillaume Haudent, and Guillaume Gueroult in the 16th, are now studied only as the precursors of La Fontaine, and from whom he may have borrowed a stray hint or the outline of a story. The unique character of his work has given a new word to the French language: other writers of fables are called *fabulistes*, La Fontaine is named *le fablier*. Referring for fuller details to the article La Fontaine, we must content ourselves here with briefly indicating his chief characteristics. He is a true poet; his verse is exquisitely modulated; his love of nature often reminds us of Virgil, as does his tenderness and pathos (see, for instance, The Two Pigeons and Death and the Woodcutter). He is full of sly fun and delicate humor; like Horace he satirizes without wounding, and "plays around the heart." Lastly, he is a keen observer of men. The whole society of the 17th century, its greatness and its foibles, its luxury and its squalor, from *Le grand monarque* to the poor *manant*, from his majesty the lion to the courtier of an ape, is painted to the life. To borrow his own phrase, La Fontaine's fables are "une ample comédie à cent actes divers."

The fables of Lessing represent the reaction against the French school of fabulists. "With La Fontaine himself," says Lessing, "I have no quarrel, but against the imitators of La Fontaine I enter my protest." His attention was first called to the fable by Gellert's popular work published in 1746. Gellert's fables were closely modelled after La Fontaine's, and were a vehicle for lively railings against the fair sex, and hits at contemporary follies. Lessing's early essays were in the same style, but his subsequent study of the history and theory of the fable led him to discard his former model as a perversion of later times, and the "Fabeln," published in 1759, are the outcome of his riper views. Lessing's fables, like all that he wrote, display his vigorous common sense. He has, it is true, little of La Fontaine's *curiosa felicitas*, his sly humor and lightness of touch; and Frenchmen would say that his criticism of La Fontaine is an illustration of the fable of the sour grapes. On the other hand he has the rare power of looking at both sides of a moral problem; he holds a brief for the stupid and the feeble, the ass and the lamb; and in spite of his formal protest against poetical ornament, there is in not a few of his fables a vein of true poetry, as in the Sheep (ii. 13) and Jupiter and the Sheep (ii. 18). But the value of the work is infinitely enhanced by the monograph on the essence of the fable which appeared at the same time, and as an illustration of which the fables were written. Much of the essay is taken up with the refutation of the theories of contemporary fabulists, De la Motte, Richer, Breitinger, Batteux, who only survive in Lessing's pages like the fly in amber. Passing over this negative criticism we may briefly state the results of Lessing's investigation. According to Lessing the ideal fable is that of Æsop. All the elaborations and refinements of later authors, from Phædrus to La Fontaine, are perversions of this original. The fable is essentially a moral precept illustrated by a single example, and it is the lesson thus enforced which gives to the fable its unity and makes it a work of art. The illustration must be either an actual occurrence or represented as such, because a fictitious case invented *ad hoc* can appeal but feebly to the reader's judgment. Lastly, the fable requires a story or connected chain of events. A single fact will not make a fable, but is only an emblem. We thus arrive at the following definition:—"A fable is a relation of a series of changes which together form a whole. The unity of the fable consists herein, that all the parts lead up to an end, the end for which the fable was invented being the moral precept."

We may notice in passing a problem in connection with the fable which had long been debated, but never satisfactorily resolved till Lessing took it in hand,—Why should animals have been almost universally chosen as the chief *dramatis personæ?* The reason, according to Lessing, is that animals have distinct characters which are known and recognized by all. The fabulist who writes of Britannicus and Nero appeals to the few who know Roman history. The Wolf and the Lamb comes home to every one whether learned or simple. But, besides this, human sympathies obscure the moral judgment; hence it follows that the fable, unlike the drama and the epos, should abstain from all that is likely to arouse our prejudices or our passions. In this respect the Wolf and the Lamb of Æsop is a more perfect fable than the Rich Man and the Poor Man's Ewe Lamb of Nathan.

Lessing's analysis and definition of the fable, though he seems himself unconscious of the scope of his argument, is in truth its death-warrant. The beast-fable arose in a primitive age when men firmly believed that beasts could talk and reason, that any wolf they met might be a werewolf, that a peacock might be a Pythagoras in disguise, and an ox or even a cat a being worthy of their worship. To this succeeded the second age of the fable, which belongs to the same stage of culture as the Hebrew proverbs and the gnomic poets of Greece. That honesty is the best policy, that death is common to all, seemed to the men of that day profound truths worthy to be embalmed in verse or set off by the aid of story or anecdote. Last comes an age of high literary culture which tolerates the trite morals and hackneyed tales for the sake of the exquisite setting, and is amused at the wit which introduces topics and characters of the day under the transparent veil of animal life. Such an artificial product can be nothing more than the fashion of a day, and must, like pastoral poetry, die a natural death. A serious moralist would hardly choose that form to inculcate, like Mandeville in his *Fable of the Bees*, a new doctrine in morals, for the moral of the fable must be such that he who runs may read. A true poet will not care to masquerade as a moral teacher, or show his wit by refurbishing some old-world maxim. (F. S.)

FABRE D'ÉGLANTINE, PHILIPPE FRANÇOIS NAZAIRE (1755–1794), a French dramatist and revolutionist, was born at Carcassonne, December 28, 1755. His real name was simple Fabre, the "d'Églantine" being an addition which he adopted in commemoration of his receiving the golden eglantine of Clemence Isaure from the Academy of the floral games at Toulouse. After travelling through the provinces as an actor, he came to Paris when about thirty years of age with the intention of continuing the same career, but being ignored by the critics he ventured to take his revenge by a comedy entitled *Les gens des Lettres ou le Provincial à Paris*, and in spite of its failure continued to bring piece after piece on the boards. Shortly after the outbreak of the revolutionary movement he entered the political arena, was chosen by Danton as his private secretary, and obtained from the electors of Paris a place in the National Convention. He distinguished himself by the extravagance of his speeches and measures, voting for the king's death, supporting the *maximum* and the law of the suspected, and giving distorted evidence against the Girondins. On the abolition of the Gregorian calendar he was one of the most active members of the committee entrusted with the formation of the republican substitute, and to him was due a large part of the new nomenclature, with its poetic *Prairial* and *Floreal*, its prosaic *Primidi* and *Duodi*, and its absurd substitution of the names of trees and beasts and implements for those of saints and heroes. The report which he made on the subject on 24th October, is not without scientific value. On January 12, 1794, he was arrested by order of the committee of public safety on a charge of malversation and forgery in connection with the affairs of the Compagnie des Indes. During his trial he displayed the greatest apparent nonchalance, sitting in an arm chair, looking out dreamily at the rain, and singing his own well-known song of *Il pleut, il pleut, bergère, rentre tes blancs moutons*. On his way to the scaffold he distributed his manuscript poems to the people.

Fabre d'Églantine left behind him seventeen plays and a number of miscellaneous productions. One only of the plays, *Le Philinthe de Molière*, still preserves its reputation as a good specimen of the second class. It professes to be a continuation of Molière's *Le Misanthrope*, but the hero of the piece is of a different character from the nominal prototype—an impersonation, indeed, of pure and simple egotism. On its publication the play was introduced by a preface, in which the author mercilessly satirizes the *Optimiste* of his rival Collin d'Harleville, whose *Châteaux en Espagne* had gained the applause which D'Églantine's *Présomptueux* had failed to win. A posthumous play, *Les Précepteurs*, steeped with the doctrines of Rousseau's *Émile*, was performed on 17th September, 1794, and met with an enthusiastic reception. The author's *Œuvres mêlées et posthumes* were published at Paris 1802, 2 vols.

See Albert Maurin, *Galerie hist. de la Révolution française*, tome ii.; Jules Janin, *Hist. de la Litt. dram.*; Chénier, *Tableau de la Litt. française*.

FABRETTI, RAPHAEL, (1618–1700), a celebrated Italian antiquary, was born in 1618, at Urbino in Umbria. A younger son, and destined to the pursuit of the law, he studied first at Cagli, and afterwards in his native city, where he took the degree of doctor at the age of eighteen years. While in Rome, preparing for practice at the bar, he early attracted the notice of Cardinal Lorenzo Imperiali, who employed him on important and difficult political affairs in Spain. He was named successively treasurer and auditor of the papal legation in that country, where he remained thirteen years. During all this time, however, his favorite classical and antiquarian studies were not neglected; and returning to Rome with the legate, Bonelli, who had been made cardinal, he was able on the journey to make important observations of the relics and monuments of Spain, France, and Italy, and to converse with the many eminent scholars of those countries who afterwards corresponded with him. At Rome he was appointed judge of appellation of the Capitol, which post he left to be, under the legate, Cardinal Cerri, auditor of the legation at his native city, Urbino. After three years he returned to

Rome, on the invitation of Cardinal Carpegna, vicar of Innocent XI., a great lover of antiquities and learning, and now found that fulness of leisure which enabled him to carry on those studies and produce those works which have made him famous. He examined with minute care the monuments and inscriptions of the Campagna. In his solitary expeditions he always rode a horse which his friends nicknamed Marco Polo, after the celebrated Venetian traveller, saying that it could discover half-hidden monuments by smelling only, and thus frequently led its master to notice what he would otherwise have passed by. Fabretti was delighted with the name, and used it himself in a letter on the study of antiquity, still in manuscript. By Innocent XII. Fabretti was made keeper of the archives of the castle of St. Angelo, a charge of great responsibility and trust, which he retained till his death.

His work *De Aquis et Aquæ-ductibus veteris Romæ*, 1680, three dissertations which cleared up a number of obscurities as to the topography of ancient Latium, is inserted in Grævius's *Thesaurus*, iv. 1677. His interpretation in this work of certain passages in Livy and other classical authors involved him in a dispute with Gronovius, which bore a strong resemblance to that between Milton and Salmasius, Gronovius addressing Fabretti as *Faber Rusticus*, and the latter, in reply, speaking of *Grunnovius* and his *titivilitia*. In this controversy Fabretti used the pseudonym Iasitheus, which he afterwards took as his pastoral name in the Academy of the Arcadians. His other works, *De Columna Trajani Syntagma*, Rome, 1683, and *Inscriptionum Antiquarum Explicatio*, Rome, 1699, throw much light on Roman antiquity, especially with the aid of the principle which he himself employed of making one monument interpret another. In the former of these works is also to be found his explication of a bas-relief, with inscriptions, now in the Capitol at Rome, representing the war and taking of Troy, known as the Iliac table. Letters and other shorter works of Fabretti are to be found in some miscellaneous publications of the time, as the *Journal des Savants*. He died at Rome, January, 1700. His collection of inscriptions and monuments was purchased from his relatives by Cardinal Stoppani, and placed in the ducal palace at Urbino, where they may still be seen.

Crescimbeni, *Le Vite degli Arcadi illustri;* Fabroni, *Vitæ Italorum*, vi. 174; Niceron, iv. 372.

FABRIANO, a town of central Italy, province of Ancona, is situated at the foot of the Apennines, and on the railway from Ancona to Rome, 35 miles S.W. of Ancona. It has paper and parchment works, tanneries, and powder mills. Among its principal buildings are the cathedral, several churches with pictures by the Fabriano school of artists, the town hall, which contains ancient inscriptions, and the museum of the Count of Rossenti, where may be seen a very fine collection of objects in ivory. Fabriano is the birth-place of the painter Gentile da Fabriano. The population of the town proper in 1870 was 6071, or including the outskirts, 7612.

FABRIANO, Gentile da, an Italian painter, was born at Fabriano about 1370. He is said to have been a pupil of Allegretto di Nuzio, but there is every probability that he received most of his early instruction from Fra Giovanni, surnamed Angelico, to whose manner his bears in some respects a close similarity. About 1411 he went to Venice, where by order of the doge and senate he was engaged to adorn the great hall of the ducal palace with frescoes from the life of Barbarossa. He executed this work so entirely to the satisfaction of his employers that they granted him a pension for life, and accorded him the privilege of wearing the habit of a Venetian noble. About 1422 he went to Florence, where in 1423 he painted an Adoration of the Kings for the church of Santa Trinita, which is preserved in the Florence gallery of paintings, and is considered his best work now extant. To the same period belongs a Madonna and Child which is now in the Berlin Museum. Fabriano had by this time attained a wide reputation, and was engaged to paint pictures for various churches, more particularly Siena, Perugia, Gubbio, and Fabriano. About 1426 he was called to Rome by Martin V. to adorn the church of St. John Lateran with frescoes from the life of John the Baptist. He also executed a portrait of the pope attended by ten cardinals, and in the church of St. Francesco Romano a painting of the Virgin and Child attended by St. Benedict and St. Joseph, which was much esteemed by Michelangelo, but is no longer in existence. Fabriano died about 1450. Michelangelo said of him that his works resembled his surname Gentile, noble or refined. They are full of a quiet and serene joyousness, and he has a naïve and innocent delight in splendor and in gold ornaments, with which, however, his pictures are not overloaded.

FABRICIUS, Caius Luscinus, a Roman general and consul, was perhaps the first member of the Fabricia gens who settled in Rome. He makes his earliest appearance in history as one of the ambassadors sent to the Tarentines to dissuade them from making war on the Romans. Elected consul in 282 B.C., he in the same year defeated the Boii and the Etruscans. When in the following year the Romans were defeated by Pyrrhus, Fabricius was sent to treat for the ransom and exchange of the prisoners, and Pyrrhus endeavored unsuccessfully to bribe him with large offers to enter his service. In 278 Fabricius was elected consul for the second time, and was successful in negotiating terms of peace with Pyrrhus, who sailed away to Italy. Fabricius afterwards gained a series of victories over the Samnites, the Lucanians, and the Bruttii, and on his return to Rome received the honor of a triumph. Notwithstanding the offices he had filled he died poor, and provision had to be made for his daughter out of the funds of the state. In honor of his military achievements and his incorruptible integrity, the senate also decreed that he and his descendants should have a burial place inside the city.

FABRICIUS, George (1516–1571), poet, historian, and archæologist, was born at Chemnitz in Upper Saxony, on the 24th April, 1516. He completed his studies at Freiberg and Leipsic. Travelling into Italy with one of his pupils, he made an exhaustive study of the antiquities of Rome. The result was the second work named below, in which the correspondence between every discoverable relic of the old city and the references and descriptions which lay scattered throughout ancient literature was traced with the minutest detail. Even learned Germans suspected that the work was in reality an ancient performance. Having returned to Germany in 1553, he was appointed director of the college of Meissen, where he died on the 13th July, 1571. In his sacred poems, which obtained for him considerable distinction, he affected to avoid every word with the slightest savor of paganism; and he blamed the poets for their allusions to pagan divinities.

The following list includes the principal works which he published, either as author or as editor:—(1) *Terentii Afri Comœdiæ sex cum castigatione duplici Joannis Rivii et G. Fabricii*, Strasburg, 1548, 8vo; (2) *Roma, cive Liber utilissimus de veteris Romæ situ, regionibus, viis, templis, aliisque ædificiis*, Basel, 1550, 8vo; (3) *Virgilii Opera cum commentariis Servii et T. C. Donati*, Basel, 1551, fol.; (4) *Virgilii Opera a Fabricio castigata*, Leipsic, 1551, 1591, 8vo; (5) *Poëmatum sacrorum libri quindecim*, Basel, 1560, 16mo; (6) *Poëmatum veterum ecclesiasticorum opera Christiana et operum reliquiæ ac fragmenta*, 1562, 4to; (7) *De Re Poëtica libri septem*, 1566, 8vo; (8) *Rerum Misnicarum libri septem*, 1569, 4to; (9) *Originum illustrissimæ stirpis Saxonicæ libri septem*, 1597, fol.; (10) *Rerum Germaniæ magnæ et Saxonicæ universæ memorabilium volumina duo*, Leipsic, 1609, fol. A life of George Fabricius was published in 1839, at Leipsic, by Professor C. G. Baumgarten Crusius. In 1845 the same biographer issued an edition of Fabricius's *Epistolæ ad Wolf. Meuerum et alios æquales*, prefixed to which there is also a short sketch *De Vita Ge. Fabricii et de gente Fabriciorum.*

FABRICIUS, Hieronymus (1537–1619), a celebrated Italian anatomist and surgeon, was surnamed Acquapendente from the episcopal city of that name, where he was born in 1537. At Padua, after a course of philosophy, he studied medicine under Fallopius, whose successor as teacher of anatomy and surgery he became in 1562. From the senators of Venice he received numerous honors, and an anatomical theatre was built by them for his accommodation. He died May 21, 1619.

The collective works of Fabricius were printed by Bohn under the title of *Opera omnia Anatomica et Physiologica*, Leipsic, 1687. The Leyden edition, published by Albinus in 1738, folio, is preferred to that of Bohn, as containing a life of the author and the prefaces of his treatises. See Anatomy, vol. i., p. 710, and Surgery.

FABRICIUS, Joannes Albertus (1668–1736), one of the most learned, laborious, and useful of bibliographers, was born at Leipsic, November 11, 1668. His father, Werner Fabricius, director of music in the church of St.

Paul at Leipsic, was the author of several works, particularly *Deliciæ Harmonicæ*, published in 1657. Joannes Albertus himself commenced his studies under his father, who on his death-bed recommended him to the care of Valentine Alberti. He studied under Wenceslas Buhl and J. S. Herrichen, and afterwards at Quedlinburg under Samuel Schmidt. It was in Schmidt's library, as he afterwards said, that he found the two works, Barthuiss's *Adversaria* and Morhoff's *Polyhistor*, which suggested to him the idea of his *Bibliothecæ*, the kind of work for which he stands pre-eminent among scholars. Having returned to Leipsic in 1686, he was the same year admitted bachelor in philosophy; and in the beginning of 1688 he took the degree of master in the same faculty, shortly after which he published his first work, *Scriptorum recentium decas*, an attack on ten writers of the day, Thomasius among them. His *Decas Decadum, sive plagiarorum et pseudonymorum centuria*, published in the following year, is the only one of his works to which he signs the name Faber. He then applied himself to the study of medicine, which, however, he relinquished for that of theology; and having gone to Hamburg in 1693, he proposed to travel abroad, when the unexpected tidings that the expense of his education had absorbed his whole patrimony, and even left him in debt to his trustee, forced him to abandon his project. He therefore remained at Hamburg, where J. F. Mayer employed him in the capacity of librarian. In 1696 he accompanied his patron to Sweden; and, on his return to Hamburg, not long afterwards, he competed for the chair of logic and philosophy. The suffrages being equally divided between Fabricius and Sebastian Edzardi, one of his opponents, the appointment was decided by lot in favor of Edzardi; but in 1699 Fabricius succeeded Vincent Placcius in the chair of rhetoric and ethics, after which he took the degree of doctor in theology at Kiel. In 1701 J. F. Mayer, who had established himself at Greifswald, caused the chair of theology in that city to be offered to Fabricius; but he refused it on account of his health. But in 1708 he accepted the professorship of theology, logic, and metaphysics, and was preparing to enter on his new office, when the senate of Hamburg induced him to remain, by adding to his professorship the office of rector of the school of St. John, then held by his father-in-law Schultz. Schultz died in 1709, but Fabricius retained the rectorship two years longer. In 1719 the landgrave of Hesse-Cassel made him so advantageous an offer that he was on the point of accepting it; but this time also the magistrates, by a seasonable increase of salary, prevailed on him to remain with them. An attempt was subsequently made to draw him to Wittenberg; but he refused to listen to the proposals made to him, and remained at Hamburg, where he died April 30, 1736.

Niceron and Reimar give a list of 128 books by Fabricius, but very many of them were only works which he had edited. One of the most famed and laborious of his works is the *Bibliotheca Latina, sive notitia auctorum veterum Latinorum quorumcunque scripta ad nos pervenerunt*, Hamburg, 1697, 8vo, a work which was republished in an improved and amended form by J. A. Ernesti, Leipsic, 1773, in three vols. 8vo. The divisions of the compilation are—the writers to the age of Tiberius; thence to that of the Antonines; and thirdly, to the decay of the language; while a fourth gives fragments from old authors, and chapters on early Christian literature. His *chef d'œuvre* is the *Bibliotheca Græca sive notitia scriptorum veterum Græcorum quorumcunque monumenta integra aut fragmenta edita extant, tum pleorumque e manuscript. ac. deperditis*, Hamburg, 1705–1728, in 14 vols. 4to, a work which has justly been denominated *maximus antiquæ eruditionis thesaurus*. It was re-arranged by Harles, at Hamburg, in 1790. Its divisions are marked off by Homer, Plato, Christ, Constantine, and the capture of Constantinople in 1453, while a sixth section is devoted to canon law, jurisprudence, and medicine. Of his remaining works we may mention—*Bibliotheca Antiquaria sive introductio in notitiam scriptorum qui antiquitates Hebraicas, Græcas, Romanas, et Christianas scriptis illustrarunt*, 1713 and 1726, 4to; *Centifolium Lutheranum, sive notitia literaria scriptorum omnis generis de B. D. Luthero*, 1728 and 1730, 8vo; as also *Salutaris lux evangelii toti orbi per divinam gratiam exoriens, sive notitia historico-chronologica, litteraria, ac geographica propagatorum per orbem totum Christianorum sacrorum*, 1731, 4to; and *Hydro-theology*, in German, 1734, 4to. Among the principal works edited by Fabricius may be named *Joannis Mabillonii iter Germanicum et Joannis Launoii de Scholis celebribus a Carolo Magno et post Carolum Magnum in occidente instauratis liber*, 1717, 8vo.

The details of the life of Fabricius are to be found in *De Vita et Scriptis J. A. Fabricii Commentarius*, by his son-in-law, H. S. Reimar, published at Hamburg, 1757. This is the work whence Niceron, Chauffepié, and other writers on the subject have borrowed their materials. Niceron's work is entitled *Mémoires pour servir à l'histoire des hommes illustres dans la république des lettres, avec un catalogue raisonné de leurs ouvrages*, Paris, 1729–1745.

FABRICIUS, Johann Christian (1745–1808), one of the chief founders of scientific entomology, was born at Tondern in Schleswig, January 7, 1745. His father was a physician of enlightened views, who encouraged his son's inclination to study the natural sciences, and, after educating him at Altona and Copenhagen, sent him to Upsala, where, attending the lectures of the great Linnæus, his future destiny, as he himself says, appears to have been laid. Of his career, apart from entomology, it may be briefly recorded that he devoted his attention professionally to political economy, and, after lecturing on that subject in 1769, was appointed a few years later professor of natural history, economy, and finance at Kiel, in which capacity he wrote various works, chiefly referring to Denmark, and of no special interest. He also published a few other works on general and natural history, botany, and travel (of which the *Reise nach Norwegen*, 1779, deserves separate mention),—for, although his professional stipend was small, he extended his personal researches into every town in northern and central Europe where a natural-history museum was to be found. In 1771 he married the daughter of Counsellor Ambrosius of Flensborg, by whom he had two sons and one daughter; and he died on 3d March, 1808.

It is, however, purely as an entomologist that the memory of Fabricius survives, aided perhaps in this country by the fact that he visited Great Britain many times after 1767, exhibiting a marked partiality for English naturalists, amongst whom were Solander, Sir Joseph Banks, Drury, Hunter, Francillon, Pennant, and Greville. Sir Joseph Banks's specimens, indeed, formerly in the collection of the Linnæan Society, and now separately treasured in the British Museum, still retain the labels written by Fabricius, and are often consulted by entomologists as evidence of his views. For many years his great scientific reputation rested upon the system of classification, which (it can scarcely be said in opposition to that of his revered master Linnæus) he founded upon the structure of the mouth-organs, instead of the wings. No scheme, however, based upon solitary characters suffices any longer for the comprehension of the vast number of forms now known to science; and, although the value of the cibarian organs is still fully recognized, the system exclusively founded on them has long since passed into disuse. But the name of Fabricius is indelibly stamped upon the science, as he had a keen eye for specific differences, and possessed the art of describing in a marvellously terse and accurate manner; and, from his being recognized as a master, added to the opportunities afforded during his many journeys to European capitals, great numbers of insects passed through his hands for description and arrangement according to his system, at a time when almost everything was new, owing to paucity of workers.

A complete list of his entomological publications (31) will be found in Hagen's *Bibliotheca Entomologiæ;* the following are the chief:—*Systema Entomologiæ*, 1775; *Genera Insectorum*, 1776; *Philosophia Entomologica*, 1778; *Species insectorum*, 1781; *Mantissa Insectorum*, 1787; *Entomologia Systematica*, 1792–1794, *with a supplement*, 1798; *Systema Eleutheratorum* (1801), *Rhyngotorum* (1803), *Piezatorum* (1804), and *Antliatorum* (1805). Full particulars of his life will be found, with a portrait, in the *Transactions of the Entomological Society of London*, vol. iv. (1845), pp. i.–xvi., where his autobiography is translated from the Danish by the Rev. F. W. Hope, then president of the society. There is also a good account by Professor Westwood, in the article "Insecta," *British Cyclopædia*, p. 881. Baron Walckenaer's verbose life in the *Biographie Universelle*, like Latreille's "Notice Biographique" in the *Annales du Muséum d'Histoire Naturelle*, ii. 393 (1808), contains important errors.

FABRONI, Angelo (1732–1803), a celebrated Italian biographer, was born at Morradi, Tuscany, 25th September, 1732. After studying at Faenza under the grammarian Girolamo Ferri, he entered the Roman college founded for the education of young Tuscans. On the conclusion of his three years' curriculum, he resolved, being determined to attain to literary distinction, to continue his stay in Rome, and having been introduced to the celebrated Jansenist Bottari, received from him the canonry of S. Teresa in Trastevere. Some time after this he was chosen to preach a discourse in the pontifical chapel before Benedict XIV., and made such a favorable impression that the pontiff settled on him an annuity left by the Countess Rospigliosi to young men who had taken a degree in law. With the possession of this annuity Fabroni was able to devote his whole time to study. Besides his other literary labors, he commenced at Pisa in 1771 a literary journal, which he continued till 1796. About 1772 he made a journey to Paris, where he formed the acquaintance of Condorcet, Diderot, D'Alembert, Rousseau, and most of the other eminent Frenchmen of that age. He also spent four months in London. He died at Pisa 22d September, 1803.

The following are his principal works:—*Vitæ Italorum doctrina excellentium qui sæculis XVII. et XVIII. floruerunt*, Pisa, 1778–1799, 1804–1805, 20 vols. 8vo (the last two vols. were published posthumously, and contain a life of the author); *Laurentii Medicei Magnifici Vita*, Pisa, 1784, 2 vols. 8vo; *Leonis X. pontificis maximi Vita*, Pisa, 1797; and *Elogi di Dante Alighieri, di Angelo Poliziano, di Lodovico Ariosto, e di Torq. Tasso*, Parma, 1800.

FABROT, Charles Annibal (1580–1659), a French jurisconsult, was born at Aix in Provence, 15th September, 1580. At an early age he made great progress in the ancient languages and in the civil and the canon law; and in 1602 he received the degree of doctor of law, and was made avocat to the parlement of Aix. In 1609 he obtained a professorship in the university of his native town. He is best known by his translation of the *Basilica*, which may be said to have formed the code of the Eastern empire till its destruction. This work was published at Paris in 1647 in 7 vols. fol., and obtained for its author a considerable pension from the chancellor Seguier, to whom it was dedicated. Fabrot likewise rendered great service to the science of jurisprudence by his edition of Cujas, which comprised several treatises of that great jurist previously unpublished. He also edited the works of several Byzantine historians, and is besides the author of various antiquarian and legal treatises. He died at Paris 16th January, 1659.

FABYAN, Robert, an English chronicler, sprung from an Essex family, is said by Bishop Tanner to have been born in London about the middle of the 15th century. Even the date of his death, 1512, is an inference from that upon which his will was proved, namely, 12th July, 1513. The records of the Drapers' Company, of which he was a member, might have settled these and other chronological doubts; but in consequence of the destruction of the company's hall by fire, there are no memoranda of a date earlier than 1602. All the ascertained details of his life are given in the biographical preface to Sir Henry Ellis's admirable edition of Fabyan's *Chronicles*. From this source we learn that Fabyan was alderman for the ward of Farringdon-Without, and that in 1493 he was appointed to the office of sheriff. In 1502, though he is believed on good grounds to have been very rich, he resigned the former office on the plea of poverty, not wishing probably to be elected to the expensive position of Lord Mayor, as he had a very numerous family. Fabyan's *Chronicle* extends from the time when "Brute entryd firste the Ile of Albion" to the year 1485. In subsequent editions it was continued by unknown authors to the year 1559. There have been five editions of the work,—the first printed in 1516 by Pynson, the second by Rastell in 1533, the third by Reynes in 1542, the fourth by Kyngeston in 1159. The fifth, in the preparation of which all the previous editions were compared, was published by Sir Henry Ellis in 1811. For its exposure of ecclesiastical abuses, Wolsey, it is said, ordered many copies of the first edition to be burnt,—hence its scarcity. The second edition was not published until after the cardinal's death. A great merit of the work consists in its details of city government and ceremonial. Wharton, indeed, observes that, in the eyes of the chronicler, a lord mayor of London seemed to be as august a personage as a king of England, and a city company's dinner as important an event as an English victory in France or a constitutional struggle at home. Ellis, it may be added, suggests that the part of the history which may have excited the hostility of Wolsey was an abstract of the Commons Bill, 11th year of Henry IV., for the resumption of ecclesiastical property. But the story of the suppression of the first edition appears to rest on the uncorroborated assertion of Bayle. In col. 256, vol. i. of Anthony à Wood's *Athenæ Oxonienses* (Bliss's edition, 4 vols., 1813–1820) there is an entry to the effect that Fabyan was "born in London, bred in grammaticals and something in logicalls in this university." In this account it is stated that Fabyan died in February, 1511.

FACCIOLATI, Jacopo (1682–1769), was born at Toriggia, in the province of Padua, in 1682. He owed his admission to the seminary of Padua to Cardinal Barberigo, who had formed a high opinion of the boy's talents. As professor of logic, and regent of the schools, Facciolati was the ornament of the Paduan university during a period of forty-five years. He published improved editions of several philological works, such as the *Thesaurus Ciceronianus* of Nizolius, and the polyglot vocabulary known under the name of Calepino. The latter work, in which he was assisted by his pupil Forcellini, he completed in four years—1715 to 1719. It was written in seven languages, and suggested to the editor the idea of his *opus magnum*, the *Totius Latinitatis Lexicon*, 4 vols. fol., Padua, 1771. In the compilation of this work the chief burden seems to have been borne by Facciolati's pupil Forcellini, to whom, however, the lexicographer allows a very scanty measure of justice, though the work occupied thirty years of his life. Perhaps the best testimony to the learning and industry of the compiler is the well-known observation that the whole body of Latinity, if it were to perish, might be restored from this lexicon. Facciolati's mastery of Latin style, as displayed in his epistles, has been very much admired for its purity and grace. In or about 1739 Facciolati undertook the continuation of Papadopoli's history of the university of Padua, carrying it on to his own day. Facciolati was known over all Europe as one of the most enlightened and zealous teachers of the time; and among the many flattering invitations which he received, but always declined, was one from the king of Portugal, to accept the directorship of a college at Lisbon for the young nobility. He died in 1769. His history of the university was published in 1757, under the name *Fasti Gymnasii Patavini*. In 1808 a volume containing nine of his *Epistles*, never before published, was issued at Padua.

FACTORS, in mercantile law, are agents entrusted with goods for the purpose of sale. The general rule as to sales at common law is that no person but the true owner can give a title to a purchaser. If, therefore, a factor or any similar kind of agent, being in possession of goods belonging to his principal, dealt with them in any unauthorized way, the persons dealing with him acquired no right as against the real owner. The inconvenience and injustice of this rule are apparent. A merchant *bonâ fide* buying goods from a person who was in possession of them, and had what among mercantile men are called the documents of title, was liable to have his rights defeated by the appearance of the real owner, who repudiated the transaction and recovered the goods. Or an agent might pledge the goods entrusted to him for advances made to him in good faith on that security, and the unfortunate lender might find that the goods belonged to a principal, and that he had no security for his loan. It thus became necessary in such cases to inquire into the real ownership of the goods and the nature of the agent's authority,—an intolerable necessity in trade. Accordingly the Factors Acts were passed for the protection of such transactions.

The 4 Geo. IV. c. 83 was an Act for the "better protection of the property of merchants and others who may hereafter enter into contracts or agreements in relation to goods, wares, and merchandise entrusted to factors or agents." It was followed by the 6 Geo. IV. c. 94, the principal Factors Act, the second section of which enacts that "persons entrusted with, and in possession of, any bill of lading, Indian warrant, dock warrant, warehouse-keeper's certificate, warrant or order for the delivery of goods, shall be deemed and taken to be the true owner of the goods, so far as to give validity to sales made by them to buyers," without notice of the fact that they are not the real owners. When a factor pledges goods deposited with him as security for an antecedent debt, the pledger shall acquire no further interest in the goods than was possessed by the factor himself. By section 4, contracts made with agents for the purchase of goods consigned to them shall be held binding upon the owners notwithstanding that the purchaser had notice that the vendors were only agents: *provided* such contracts be made in the usual course of business, and that the purchaser had not notice that the agent had no authority to sell.

By the Amendment Act, 5 and 6 Vict. c. 39 (which recites that much litigation had arisen on the construction of the former statute, and that it is necessary to explain and extend the provisions thereof), it is enacted "that any agent who shall thereafter be entrusted with the possession of goods, or of the documents of title to goods, shall be deemed and taken to be owner of such goods and documents, so far as to give validity to any contract or agreement by way of pledge, lien, or security *bonâ fide* made to any person with such agent, as well for any original loan, advance, or payment, made on the security of such goods or documents, as also for any further or continuing advance." And such contracts shall be binding on the owner notwithstanding notice of the agency. *Bonâ fide* deposits in exchange are protected, *i.e.*, where an agent pledges goods consigned to him in exchange for other goods on which the person delivering them up had at the time a valid lien. In all cases the transaction must be *bonâ fide*, and without notice that the agent is acting beyond his authority or in bad faith as regards his principal.

"These Acts," says Mr. Benjamin in his treatise on *The Sale of Personal Property*, "apply solely to persons entrusted as factors or commission merchants, not to persons to whose employment a power of sale is not ordinarily added, as a wharfinger, who receives goods usually without a power to sell. The statute is limited in its scope to mercantile transactions, to dealings in goods and merchandise, and does not embrace sales of furniture or goods in possession of a tenant or bailee for him." And the courts of law have unfortunately felt themselves constrained to put a very narrow interpretation on the scope of the Acts. The most remarkable case was that of Fuentes *v.* Montes (*Law Reports*, 3 Common Pleas, 268). Here the plaintiffs, wine merchants in Spain, had consigned some casks of sherry to a London factor for sale, but afterwards revoked his authority. He, while in possession of the wine, but after the revocation, pledged it as security for advances made by the defendant, who acted in good faith, and in entire ignorance of the revocation. The court held that the words "entrusted with and in possession of" referred to the time of the pledge only, and that the factor was not so entrusted at the time of the pledge. This decision, which unsettled the confidence of merchants in dealing with apparent owners of goods, and a general uncertainty as to the true construction of the enactments, led to the passing of the last Factors Act (40 and 41 Vict. c. 39). The second section overrules the decision in Fuentes *v.* Montes, by providing that a revocation of authority shall not affect the right of persons purchasing from factors without notice of such revocation. Then the Act goes on to provide for other cases of apparent ownership in which the same hardships had arisen which the Factors Acts were intended to meet. Thus, where goods have been sold, and the vendor has been permitted to retain possession of the documents of title, any sale by him or his agent will be as valid and effectual as if he or his agent were a person entrusted with, or in possession of, the goods under the Factors Acts. A case recently decided (Johnson *v.* the Credit Lyonnais Company) will illustrate the purpose of this enactment. A, a tobacco broker, had 50 hogsheads of tobacco lying in dock for which warrants were issued to him. He sold it to B, who paid for it, but left the warrants in A's hands, and took no steps to have any change made in the books of the dock company as to the ownership. In the mean time A obtained advances on the tobacco from C and D, handing over to them the dock warrants. It was held that these transactions were not protected as against B; under the new Act such transactions are protected. The fourth section deals with cases in which goods have been sold, and the vendee has got possession of the documents of title, although some lien or other right remains to the vendor. Dealings with the vendee in respect of the goods, and in ignorance of the vendor's right, are protected. The fifth section protects *bonâ fide* transfers of documents of title for a previous vendor's lien or right of stoppage *in transitu*. (E. R.)

FACTORY ACTS. The long series of Factory Acts, culminating in the home secretary's bill of the present session (1878), constitutes one of the most important chapters in the history of modern English legislation. The Acts assert the right of the state to control the industrial organizations which depend upon the labor of women and children. As yet the freedom of the adult male laborer has been held sacred from the interference of the legislature, but it is necessarily involved, to some extent, in the protection exercised over persons whose co-operation is necessary to his work. The gradual rise of the important principle that, in the interests of the moral and physical well-being of the community, the labor of women and children should be restricted by law within reasonable limits may be seen by a glance at the Factory Bills introduced in parliament since the beginning of the century.

In 1802 an Act was passed "for the Preservation of the Health and Morals of Apprentices and others employed in Cotton and other Mills, and Cotton and other Factories." The immediate cause of passing this bill was the fearful spread throughout the factory district of Manchester of epidemic disease, which made dreadful havoc among the youthful laboring population on account of their scanty mode of living and peculiar way of working.[1] Pauper children from the agricultural districts of the south were sent to the northern counties to work in the factories which sprang up there in consequence of their superior supply of water-power. Their long hours of labor, the wretched accommodation provided for them, and the over-crowding of workmen in mills and factories, caused the alarming epidemic fevers of those times and districts. The Act of 1802 subjected all mills employing three or more apprentices, or twenty other persons, to the rules and regulations of the Act. The walls were to be washed with quicklime and water, a sufficient number of windows was to be provided; the apprentices were always to have two suits of clothing, one to be new every year. The most important regulation, however, was that which fixed the hours of work at twelve per day, and prohibited work altogether from 9 o'clock at night to 6 in the morning. This Act, being intended to meet the evils of the apprentice system, did not extend to factories where children residing in the neighborhood were employed. The use of steam-power had meanwhile caused the growth of factories in populous town districts. In 1819 an Act was passed for the regulation of cotton mills: children were not to be admitted before the age of nine, and between that age and sixteen were restricted to twelve hours a day, exclusive of an hour and a half for meal-time. In 1825 Sir John Cam Hobhouse's Bill was passed, which established a partial holiday on Saturday, and provided penalties for offences against the Act. An amending Act was passed (10 Geo. IV. c. 51), and in 1831 (by the 1 and 2 Will. IV. c. 39) night work in the cotton factories was prohibited for persons between nine and twenty-one years of age; the working day for persons under eighteen was to be twelve hours, and on Saturdays nine. This was the time of the great political movement which brought about the Reform Act of 1832, and the factory question entered into and to some extent complicated the purely political issues. In the wool districts the unions of the working men clamored for a restriction of non-adult labor in factories to ten hours a day, and their demand was supported by the Conservative and country party, out of opposition to the manufacturers, who were for the most part keen supporters of the Reform Bill. The wool factories had not been touched by the recent legislation, and the sufferings of the overworked children appealed powerfully to the imagination of the public. After much discussion in committees and commissions, the Act of 1833 (3 and 4 Will. IV. c. 103) was passed. Night work (between 8.30 P.M. and 5.30 A.M.) was prohibited to persons under eighteen in cotton, wool, worsted, hemp, flax, tow, and linen spinneries and weaving mills; children from nine to thirteen were not allowed to work more than 48 hours a week; and young persons from thirteen to eighteen were restricted to 68 hours a week. In silk factories children might be admitted under nine, and children under thirteen were to be allowed ten hours a day. Provision was also made for school attendance and for the appointment of factory inspectors to watch over the working of the law. The manufacturers, dreading the economical results of the loss of children's labor, subsequently induced the Government to propose that children over eleven should be allowed to work the full time of 69 hours a week, but in the face of the agitation for greater restrictions this amendment was not persisted in.[2]

---

[1] Von Plener, *English Factory Legislation*, p. 1.

[2] One of the consequences of the restrictions imposed on the employment of children was the increased use of machinery as a sub-

The extension of the Factory Acts to unprotected industries now engaged the attention of philanthropists. A Mining Act (5 and 6 Vict. c. 99) was passed, which prohibited under-ground work to children under ten and women. In 1844 the Factory Act, 7 Vict. c. 15, was passed. Children from eight to thirteen might be employed in textile industries for not more than six hours and a half per day, but in factories where "young persons" restricted to ten hours a day were employed, children might also be employed for ten hours a day on alternate days. Children so employed had to attend school during the "half time." Adult women were brought under the same rules as "young persons." Lord Ashley's[1] Printworks Act followed in 1845. A Ten Hours Bill was at last carried in 1847 (10 Vict. c. 29). Women and young persons were restricted to ten hours a day, and the legal working day was fixed from 5.30 A.M. to 8.30 P.M. By employing protected persons in relays, manufacturers were enabled to keep their works going during the whole of the legal day; and to meet this evasion, as it was deemed to be, of the factory legislation a uniform working day was fixed, 13 and 14 Vict. c. 54. Young persons and women were allowed to work only between 6 A.M. and 6 P.M.—an hour and a half being allowed for meal-time. No protected person was to work on Saturday after 2 P.M. By the 16 and 17 Vict. c. 104, children were limited to a legal day beginning at 6 A.M. and ending at 6 P.M. Bleaching and dyeing works were subjected to similar restrictions by Acts passed in 1860 and 1862, calendering and finishing works in 1863 and 1864. Lace factories were placed under the regulations of the Factories Acts by 24 and 25 Vict. c. 117. Night work in bakehouses was prohibited to young persons under eighteen, by 26 and 27 Vict. c. 40. After the report of a commission, a new Factory Acts Extension Act was passed (27 and 28 Vict. c. 48), which brought manufactories of earthenware, percussion caps, lucifer matches, and cartridges, paper-staining, and fustian-cutting within the scope of the factory legislation. In 1867 a distinction was drawn in legislation between factories and workshops. The Factory Acts Extension Act of that year applied to all furnaces, iron and copper works, machine manufactories, metal and gutta-percha factories, paper-mills, glass-works, printing offices, and bookbinders' shops, and to all establishments in which over 50 persons are employed for a period of a hundred days. Special modifications, however, were introduced to suit the requirements of the different trades. In the same year the Workshop Regulation Act was passed, for small trades and handicrafts, fixing the working day for children at 6 A.M. to 8 P.M., and for young persons and women from 5 A.M. to 9 P.M. Printing, bleaching, and dyeing works were brought under the general law by the Factory and Workshop Act, 1870. In 1871 another Act with the same title was passed, which, *inter alia*, subjected Government factories to the general law. The Factory Act of 1874, the last of the series, raised the minimum of age in children to ten.

By these various enactments the state has emphatically taken under its protection the whole class of children and young persons employed in manufacturing industries. It has done this in the name of the moral and physical health of the community. The slow but steady advance of the principle of interference may be traced in the titles of the successive statutes. It is needless here to discuss the wisdom of the policy, which has now received *en bloc* the stamp of legislative approval. The substantive law of the Factories Acts has been re-enacted in a measure laid before parliament in the present session, which has already (May, 1878) passed both Houses. In the debates in the Commons the only question of principle seriously raised was whether the freedom of adult women ought to be curtailed by legislative interference. Mr. Fawcett's motion in the negative was rejected by a large majority.

The following outline will give some idea of the scope of the law relating to factories and workshops consolidated by the new measure:

Part I. contains the general law relating to factories and workshops, under the following heads—(1) Sanitary Provisions; (2) Safety; (3) Employment and meal hours; (4) Holidays; (5) Education; (6) Certificates of fitness for employment; (7) Accidents.

(1.) Under the first head, the buildings must be kept in a clean state, and free from effluvia arising from any drain, privy, or other nuisance.

(2.) The second contains provisions for the fencing of dangerous machinery, and restrictions on the employment of children and young persons in cleaning, etc., machinery in motion.

(3.) A child, young person, or woman shall not be employed except during the period of employment fixed as follows:—

(*a.*) In textile factories.—*For young persons and women*, the period shall be from 6 A.M. to 6 P.M. or 7 A.M. to 7 P.M.; on Saturday, from 6 A.M. till 1 P.M. for manufacturing processes, and 1.30 for all employment, if one hour is allowed for meals; otherwise at 12.30 and 1. Or if the work begins at 7 A.M., it shall end on Saturdays at 1.30 and 2 P.M. respectively. For meal times two hours at least on week days, and on Saturdays half an hour, must be allowed. Continuous employment without a meal time of at least half an hour not to exceed four hours and a half.

For children. Employment to be for half time only (in morning or afternoon sets, or alternate days). The work-day is the same as above. A child must not be employed for two successive periods of seven days in the same set, whether morning or afternoon, nor on two successive Saturdays, nor on Saturday in any week if he has already on one day been employed more than five hours and a half. Nor shall a child be employed on two successive days, nor on the same day in two successive weeks.

(*b.*) In non-textile factories.—*For young persons and women.* Period of employment same as before, ending at 2 P.M. on Saturdays; meal times not less than an hour and a half, on Saturday half an hour; continuous employment without a meal not to exceed 5 hours; these regulations also apply to *young persons in workshops.*

For children. Half-time arrangements generally the same as before, continuous employment without a meal not to exceed 5 hours.

Women in workshops are subject to the same regulations as young persons, if young persons or children are employed; if not, the period of employment for a woman in a workshop shall be from 6 A.M. to 9 P.M. (on Saturday 4 P.M.). Absent time for meals, etc., must be allowed to the extent of four hours and a half (Saturdays two hours and a half).

The employment of young persons or children at home, when the work is the same as in a factory or workshop, but no machine power is used, is also regulated,—the day being fixed at 6 A.M. to 9 P.M.; for children, 6 A.M. to 1 P.M., or 1 P.M. to 8. Meal times in factories or workshops must be simultaneous, and employment during such meal times is forbidden. The occupier of a factory or workshop must issue a notice of the times of employment, etc. No children under 10 shall be employed.

(4.) The following holidays shall be allowed to all protected persons:—Christmas day, Good Friday (or the next public holiday), and eight half-holidays, two of which may be commuted for one entire holiday.

(5.) Occupiers must obtain a weekly certificate of school attendance for every child in their employment.

(6.) Medical certificates of fitness for employment are required in the case of children and young persons under 16. When a child becomes a young person a fresh certificate is necessary.

(7.) Notice of accidents, causing loss of life or bodily injury, must be sent to the inspector and certifying surgeon of the district.

Part II. contains special provisions for particular classes of factories and workshops, such as bake-houses, print-works, bleaching and dyeing works. The third schedule to the Act contains a list of special exceptions too numerous to be given in detail.

Part III. provides for the administration of the law. Two classes of officers are to be appointed by the secretary of state, viz., (1) inspectors, charged with the duty of inspecting and examining factories and workshops at all reasonable times, and of exercising such other powers as may be necessary to the carrying out of the Act; and (2) certifying surgeons to grant certificates of fitness under the Act. Numerous other sections relate to penalties and legal proceedings.

Part IV. defines the principal terms used in the Act. Child means a person under fourteen years of age; a "young person" is between fourteen and eighteen; "a woman" means a woman over eighteen. Other sections apply the Act to Scotland and Ireland, with a temporary saving for the employment of children under ten and children over thirteen (lawfully employed at the time of the passing of the Act). Previous enactments are repealed. (E. R.)

FACULTY, in law, is a dispensation or license to do that which is not permitted by the common law. The word in this sense is used only in ecclesiastical law. Thus, any alteration or enlargement of a church requires a license

---

stitute. In 1835 (before the Factory Act), there were 56,455 children employed in 3164 factories; in 1838 (under the Factory Act), 29,283 children were employed in 4217 factories.—*Von Plener's English Factory Legislation*, p. 22.

[1] Afterwards earl of Shaftesbury, whose name, more than any other, is entitled to be associated for ever with the English factory legislation.

or faculty from the ordinary. The faculty court belonging to the archbishopric of Canterbury is presided over by the Master of the Faculties, who has power "to grant dispensations, as to marry, to eat flesh on days prohibited, to hold two or more benefices incompatible," etc. (Burn's *Ecclesiastical Law*).

In universities and other learned bodies faculty means the association of professors or practitioners of some special branch of learning or skill. Thus, in the Scotch universities we have the usual faculties of arts, medicine, divinity, and law. Again, the society of advocates of the court of session, and local bodies of legal practitioners, are described as faculties. The word, in this sense, has fallen into disuse in England.

FAENZA, a city of Italy, at the head of a circondario in the province of Ravenna, situated in a fertile plain about 20 miles S.W. of Ravenna, at the junction of the Zanelli canal with the Lamone (the ancient Anemo), and on the railway between Bologna and Ancona. It is regularly built, surrounded by walls, and defended by a citadel. Around the market-place (a spacious square in the centre of the town with a fine marble fountain) are arranged the cathedral (St. Constantius), the town-hall, the theatre, and many handsome residences. The town-hall or *palazzo communale* was formerly the palace of the Manfredi family, and is famous as the scene of the assassination of Galeotto Manfredi by his wife, which has been dramatized by Monti. Several of the churches in the town possess valuable paintings, among which are a few by Girolamo da Treviso. A college, a school of painting, a hospital, and two orphan asylums are among the public buildings of importance The majolica ware, which takes its French name of "fayence" from the town, still continues to be manufactured, though not to such an extent as formerly; and there are also paper-mills and factories for spinning and weaving silk. A considerable trade is carried on by the canal which was opened in 1782 by Signor Zanelli, to unite the Lamone with the Po di Primaro at Sant' Alberto. About 2½ miles from the town there are thermal and saline springs, from the latter of which salt is extensively manufactured. The same product is also obtained from the cinericious tufa on the banks of the Lamone, and between the Lamone and Sentria runs an abundant vein of sulphur. The population of the town in 1871 was 36,299.

Faenza is identified with the Faventia which is noted in history as the place where Carbo and Norbanus were defeated with great loss by Metellus, the general of Sulla, in 82 B.C. In the time of Pliny it was celebrated for the whiteness of its linen. It was greatly favored by the emperor Constantine, and during the Middle Ages it continued to be a place of some importance. Dante mentions it as the seat of the powerful family of the Pagani. In 1241 it was captured by Frederick II. after a protracted siege, and not long after the Bolognese obtained temporary possession. A period of independence followed, till the Manfreds, who settled in the city about 1286, established their supremacy. In 1376 the town was pillaged by the notorious Sir John Hawkwood of Essex (the Giovanni Acuto of the Italian chronicles), who served under Gregory XI. The Manfredi power came to an end in 1500, and in 1509 Pope Julius II. secured Faenza against the Venetians by the battle of Ghiara d'Adda. It continued subject to the church till the unification of Italy. At a little distance is the scene of the first battle between the pontifical forces and the French in 1797. The town claims the honor of being the birthplace of Torricelli, and has erected a statue to his memory.

FÆSULÆ. See FIESOLE.

FAHLCRANTZ, CHRISTIAN ERIK (1790–1866), a Swedish author, was born at Stora Tuna in Sweden on the 30th of August, 1790. The family to which he belonged was a gifted one, and of his brothers, two, Carl Johan the landscape-painter, and Axel Magnus the sculptor, became hardly less distinguished than himself. In 1804 he entered on his career as a student; in 1821 he became tutor in Arabic, and in 1825 professor of the Oriental languages at the university of Upsala. In 1828 he entered the church, but earlier than this, in 1825, he published his polemical and satirical poem of *Noah's Ark*, which enjoyed an immense success. In 1826 appeared a second part of *Noah's Ark*, together with various pieces, original and translated. In 1835 Fahlcrantz brought out his epic of *Ansgarius*, which grew as time went on, and finally consisted, in 1846, of 14 books. In 1842 he was made a member of the Swedish Academy, and in 1843 entered into a furious controversy with the famous novelist, Almqvist, against whose writings he published a thick volume in 1845–46. In 1849 he was made bishop of Vesterås, and his next literary work was an archæological study on the beautiful ancient cathedral of his diocese. In the course of the years 1858–61 appeared the six volumes of his *Rome as it was and is*, a theological polemic, mainly directed against the Jesuits. In 1863 he began to collect and issue his complete works, a task which was still unfinished when he died on the 6th of August, 1866, a few hours after conducting service in Vesterås Cathedral.

Of the writings of no Swedish author so much as of those of Fahlcrantz can it be said *facit indignatio versus*. He writes ill, except at a white heat of scorn or anger. His early humoristic poem, *Noah's Ark*, was once extremely popular; it was a satire upon the literary life of 1820, under the form of a parody of the world before the flood. It is still readable, which is more than can be said of *Ansgarius*, a very tedious production. Fahlcrantz will live, if he live at all, by the point and venom of his wit.

FAHRENHEIT, GABRIEL DANIEL (1686–1736), well known for the improvements made by him in the construction of the thermometer and barometer, was born at Dantzic, May 14, 1686. He early relinquished trade for the study of natural philosophy; and, after having travelled in Germany and England, he settled in Holland, where Gravesande and other men of science were his teachers and friends. In 1714 he conceived the idea of substituting mercury for spirits of wine in the construction of thermometers. He took as the zero of his thermometric scale the lowest temperature observed by him at Dantzic during the winter of 1709, which he found was that produced by mixing equal quantities of snow and sal-ammoniac. The space between this point and that to which the mercury rose at the temperature of boiling water he divided into 212 parts. At the time of his death, which took place on September 16, 1736, Fahrenheit was engaged in the contrivance of a machine for draining inundated land. See THERMOMETER and METEOROLOGY.

FAIR. A fair is defined as a "greater species of market recurring at more distant intervals;" both have been distinguished by Lord Coke from "mart," which he considers as a greater species of fair; and all three may comprehensively be described as customary or legalized public places for the sale of commodities (including labor). Thus, in England, no fair can be held without a grant from the sovereign, or prescription which presupposes such grant. In France, the establishment and abolition of fairs—with the exception of cattle markets and the markets of the metropolis—are generally left to the discretion of the departmental prefects. The most commonly accepted derivation of the word fair is from *feriæ*, a name which the church borrowed from Roman custom and applied to her own festivals. A fair was generally held during the period of a saint's feast, and in the precincts of his church or abbey—the time and the place of the chief popular assemblages; but in England this desecration of church and churchyard was first forbidden by the statutes of Henry III. and Edward II. Most of the famous fairs of mediæval England and Europe, with their tolls or other revenues, and, within certain limits of time and place, their monopoly of trade, were grants from the sovereign to abbots, bishops, and other ecclesiastical dignitaries. Their "holy day" associations are preserved in the German word for fairs, *messen;* as also in the *kirmiss*, "church mass," of the people of Brittany. So very intimate was the connection between the fair and the feast of the saint that the former has very commonly been regarded as an off-shoot or development of the latter. Nevertheless, there are grounds for the supposition that fairs were already existing national institutions, long before the church turned or was privileged to turn them to her own profit. The first charter of the great fair of Stourbridge, near Cambridge, was granted by King John for the maintenance of a leper hospital; but the origin of the fair itself is ascribed to Carausius, the rebel emperor of Britain, 207 A.D. At all events, it may be seen from the *data* given in Mr. Herbert Spencer's *Descriptive Sociology* that the country had then arrived at the stage of development where fairs might have been recognized as a necessity. The Romans also appear to have elaborated a market-law similar to that in force throughout mediæval Europe—though it must be observed that the Roman *nundinæ*, which some have regarded as fairs, were weekly markets. It has also been supposed that the ancient fairs of Lyons were a special privilege granted by the Roman conquerors; and Sidonius Apollinaris, 427 A.D., alludes to the fairs of the district afterwards known as the county of Champagne, as if they were then familiarly known institutions. Fairs, in a word, would not only have arisen naturally, wherever the means of communication between individual centres of production and consumption were felt to be inadequate to the demand for an interchange of commodities; but, from their very nature, they might be expected to show some essential resemblances, even in points of legislation, and where no international transmission of custom could have been possible. Thus, the fair courts of pre-Spanish Mexico corresponded very closely to those under whose supervision the Beaucaire fair is conducted in the present day. They resembled our own courts of piepowder. The Spaniards, when first they saw the Mexican fairs, were reminded of the like institutions in Salamanca and Granada. The great fair or market at the city of Mexico is said to have been attended by about 40,000 or 50,000 persons, and is thus described by Prescott:—

> "Officers patrolled the square, whose business it was to keep the peace, to collect the dues imposed on the various kinds of merchandise, to see that no false measures or fraud of any kind were used, and to bring offenders at once to justice. A court of twelve judges sat in one part of the *tianguez* clothed with those ample and summary powers which, in despotic countries, are often delegated even to petty tribunals. The extreme severity with which they exercised those powers, in more than one instance, proves that they were not a dead letter."

But notwithstanding the great antiquity of fairs, their charters are comparatively modern—the oldest known being that of St. Denys, Paris, which Dagobert, king of the Franks, granted (642 A.D.) to the monks of the place "for the glory of God, and the honor of St. Denys at his festival." The first recorded grant in England appears to be that of William the Conqueror to the bishop of Winchester, for leave to hold an annual "free fair" at St. Giles's hill. The monk who had been the king's jester received his charter of Bartholemew fair, Smithfield, in the year 1133. And in 1248 Henry III. granted a like privilege to the abbot of Westminster, in honor of the "translation" of Edward the Confessor. Sometimes fairs were granted to towns as a means for enabling them to recover from the effects of war and other disasters. Thus, Edward III. granted a "free fair" to the town of Burnley in Rutland, just as, in subsequent times, Charles VII. favored Bordeaux, after the English wars, and Louis XIV. gave fair charters to the towns of Dieppe and Toulon. The importance attached to these old fairs may be understood from the inducements which, in the 14th century, Charles IV. held out to traders visiting the great fair of Frankfort-on-the-Maine. The charter declared that both during the continuance of the fair, and for eighteen days before and after it, merchants would be exempt from imperial taxation, from arrest for debt, or civil process of any sort, except such as might arise from the transactions of the market itself and within its precincts. Philip of Valois's regulations for the fairs of Troyes in Champagne might not only be accepted as a fair type of all subsequent fair-legislation of the kingdom, but even of the English and German laws on the subject. The fair had its staff of notaries for the attestation of bargains, its court of justice, its police officers, its sergeants for the execution of the market judges' decrees, and its visitors—of whom we may mention the *prud' hommes,*—whose duty it was to examine the quality of goods exposed for sale, and to confiscate those found unfit for consumption. The confiscation required the consent of five or six representatives of the merchant community at the fair. The effect of these great "free fairs" of England and the Continent on the development of society was indeed great. They helped to familiarize the western and northern countries with the banking and financial systems of the Lombards and Florentines, who resorted to them under the protection of the sovereign's "firm peace" and the ghostly terrors of the pope. They usually became the seat of foreign agencies. In the names of her streets Provins preserved the memory of her 12th century intercourse with the agents and merchants of Germany and the Low Countries, and long before that time the Syrian traders at St. Denys had established their powerful association in Paris. Like the church on the religious side, the free fairs on the commercial side evoked and cherished the international spirit. And during long ages, when commercial "protection" was regarded as indispensable to a nation's wealth, and the merchant was compelled to "fight his way through a wilderness of taxes," they were the sole and, so far as they went, the complete substitute for our modern free trade.

Their privileges, however, were, from their very nature, destined to grow more oppressive and intolerable the more the towns were multiplied and the means of communication increased. The people of London were compelled to close their shops during the days when the abbot of Westminster's fair was open. But a more curious and complete instance of such an ecclesiastical monopoly was that of the St. Giles's fair, at first granted for the customary three days, which were increased by Henry III. to sixteen. The bishop of Winchester was, as we have seen, the lord of this fair. On the eve of St. Giles's feast the magistrates of Winchester surrendered the keys of the city gates to the bishop, who then appointed his own mayor, bailiff, and coroner, to hold office until the close of the fair. During the same period, Winchester and Southampton also—though it was then a thriving trading town—were forbidden to transact their ordinary commercial business, except within the bishop's fair, or with his special permission. The bishop's officers were posted along the highways, with power to forfeit to his lordship all goods bought and sold within seven miles of the fair—in whose centre stood "the pavilion," or bishop's court. It is clear, from the curious record of the *Establishment and Expenses of the Household* of Percy, fifth earl of Northumberland, that fairs were the chief centres of country traffic even as late as the 16th century. They began to decline rapidly after 1759, when good roads had been constructed and canal communication established between Liverpool and the towns of Yorkshire, Cheshire, and Lancashire. In the great towns their extinction was hastened in consequence of their evil effects on public morals. All the London fairs were abolished as public nuisances before 1855,—the last year of the ever-famous fair of St. Bartholomew; and the fairs of Paris were swept away in the storm of the Revolution.

English Fairs and Markets.—For the general reasons apparent from the preceding sketch, fairs in England, as in France and Germany, have very largely given way to markets for specialties. Even the live-stock market of the metropolis is being superseded by the dead-meat market, a change which has been encouraged by recent legislation on cattle disease, the movements of home stock, and the importation of foreign animals. Agricultural markets are also disappearing before the "agencies" and the corn exchanges in the principal towns. Still there are some considerable fairs yet remaining. Of the English fairs for live stock, those of Weyhill in Hampshire (October 10), St. Faith's, near Norwich (October 17), as also several held at Devizes, Wiltshire, are among the largest in the kingdom. The first named stands next to none for its display of sheep; while the second is the principal resort of the Scotch drovers and cattle-dealers, and supplies a large proportion of the fat stock required for the London market. Horncastle, Lincolnshire, is the largest horse fair in the kingdom, and is regularly visited by American and Continental dealers. The other leading horse fairs in England are Howden in Yorkshire (well known for its hunters), and Woolbridge (on Lady Day) for Suffolk horses. Exeter December fair has a large display of cattle, horses, and most kinds of commodities. Large numbers of Scotch cattle are also brought to the fairs of Market Harborough, Carlisle, and Ormskirk. Ipswich has a fair for lambs on 1st of August, and for butter and cheese on 1st of September. Gloucester fair is also famous for the last-named commodity. The guild or jubilee held at Preston, Lancashire, every twentieth year, occurred last in 1862. Falkirk fair, or tryst, for cattle and sheep, is one of the largest in Scotland; and Ballinasloe, Galway, holds a like position among Irish fairs. The Ballinasloe cattle are usually fed for a year in Leinster before they are considered fit for the Dublin or Liverpool markets. In 1790 there were 61,931 sheep and 8632 horned cattle exhibited at the fair, and for 1867 the returns, in the foregoing order, were 73,364 and 23,734.

French Fairs.—The most important is that of Beaucaire, once among the first in Europe. Its position on the Rhone (14 miles east of Nismes), and its connection with the canals, still enable it to maintain a high rank among the Continental markets. It lasts from the 22d to the 28th July, and is visited by about 60,000 persons, from all parts of the

Continent between Spain and the Levant; articles of all descriptions are sold at it. It is a rule that all bills due at this fair must be presented on the 27th and protested, if necessary, on the 28th.

German Fairs.—First, though no longer of world-wide importance, are those of Frankfort-on-the-Maine, Frankfort-on-the-Oder, and Leipsic. Those of Frankfort-on-the-Maine begin on Easter Tuesday and on the nearest Monday to September 8, respectively, and their legal duration is three weeks, though the limit is regularly extended. The fairs of the second-named city are *Reminiscere*, February or March; *St. Margaret*, July; *St. Martin*, November. Ordinarily they last fifteen days, which is double the legal term. The greatest of the German fairs are those of Leipsic, whose display of books is famous all over the world. Its three fairs are dated January 1, Easter, Michaelmas. The Easter one is the book fair, which is attended by all the principal booksellers of Germany, and by many more from the adjoining countries. Most German publishers have agents at Leipsic. As many as 5000 new publications have been entered in a single Leipsic catalogue. As in the other instances given, the Leipsic fairs last for three weeks, or nearly thrice their allotted duration. Here no days of grace are allowed, and the holder of a bill must demand payment when due, and protest, if necessary, on the same day, otherwise he cannot proceed against either drawer or endorser.

Russian Fairs.—These are very numerous, the chief being those of Nijni Novgorod, of Irbit in Perm, Kharkoff (January and August), Poltava (August and February), Koreunais in Koursk, Ourloupinsknia in the Don Cossack country, Krolevetz in Tchernigoff, and a third fair held at Poltava on the feast of the Ascension. It is calculated that in 1851 the aggregate value of goods sold at the above-named fairs amounted to nearly 120,000,000 silver roubles. The chief fair of Novgorod is attended by 100,000 to 130,000 persons from all parts of Asia and of eastern Europe. Thirty years ago the fair of Kiatcha, on the Russo-Chinese frontier, yielded one million sterling in revenue; but in 1867, according to Mr. Lumley, secretary to the English embassy at St. Petersburg, the sum had fallen by one half. This was in consequence of the opening of new communications, and the abolition of the Kiatcha monopoly.

Turkish Fairs.—Of these there are a very considerable number, and the vast bulk of the internal commerce of the country is transacted at them. Among the most noteworthy are the fairs of Usundji, in Roumelia, on a tributary of the Moritza, 40 miles from Adrianople; Janina in Albania; Strouga, on the lake of Orida; Novi-Bazaar in Upper Mœsia; Islioni in Thrace; Nicopoli and Prelip in Macedonia; Eski-djouma in Bulgaria; and Zeitoun and Pharsalia in Thessaly. There is a large show of western manufactures at the Usundji fair.

Indian Fairs.—The largest of these, and perhaps the largest in Asia, is that of Hurdwar, on the upper course of the Ganges. The visitors to this holy fair number from 200,000 to 300,000; but every twelfth year there occurs a special pilgrimage to the sacred river, when the numbers may amount to a million or upwards. Those who go solely for purposes of trade are Nepaulese, Mongolians, Thibetans, Central Asiatics, and Mahometan peddlers from the Punjab, Scinde, and the border states. Persian shawls and carpets, Indian silks, Cashmere shawls, cottons (Indian and English), preserved fruits, spices, drugs, etc., together with immense numbers of cattle, horses, sheep, and camels, are brought to this famous fair.

American Fairs.—The word fair, as now used in the United States, appears to have completely lost its Old World meaning. It seems to be exclusively applied to industrial exhibitions, and to what we in England would call fancy bazaars. Thus, during the civil war, large sums were collected at the "sanitary fairs," for the benefit of the sick and wounded. To the first-named class belong the State and county fairs, as they are called. Among the first and best known of these was the "New York World's Fair," opened in 1853 by a company formed in 1851. Since 1829 the "American Institute" held annual "fairs" for the encouragement of the agricultural and manufacturing arts. The chief centres of these "fairs," or exhibitions, appear to be Cincinnati, Baltimore, Boston, San Francisco, and Buffalo.

Law of Fairs.—As no market or fair can be held in England without a royal charter, or right of prescription, so any person establishing a fair without such sanction is liable to be sued, under a writ of *Quo warranto*, by any one to whose property the said market may be injurious. Nor can a fair or market be legally held beyond the time specified in the grant; and by 5 Edward III. c. 5 a merchant selling goods after the legal expiry of the fair forfeited double their value. To be valid, a sale must take place in "market overt" (open market); "it will not be binding if it carries with it a presumption of fraudulence." These regulations satisfied, the sale "transfers a complete property in the thing sold to the vendee; so that however injurious or illegal the title of the vendor may be, yet the vendee's is good against all men except the king." (In Scotch law, the claims of the real owner would still remain valid.) However, by 21 Henry VIII. c. 2 it was enacted that, "if any felon rob or take away money, goods, or chattels, and be indicted and found guilty, or otherwise attainted upon evidence given by the owner or party robbed, or by any other by their procurement, the owner or party robbed shall be restored to his money, goods, or chattels," but only those goods were restored which were specified in the indictment, nor could the owner recover from a *bonâ fide* purchaser in market-overt, who had sold the goods before conviction. For obvious reasons the rules of market-overt were made particularly stringent in the case of horses. Thus, by 2 Philip and Mary c. 7 and 31 Eliz. c. 12, no sale of a horse was legal which had not satisfied the following conditions:—Public exposure of the animal for at least an hour between sunrise and sunset; identification of the vendor by the market officer, or guarantee for his honesty by "one sufficient and credible person;" entry of these particulars, together with a description of the animal, and a statement of the price paid for it, in the market officer's book. Even if his rights should have been violated in spite of all these precautions, the lawful owner could recover, if he claimed within six months, produced witnesses, and tendered the price paid to the vendor. Tolls were not a "necessary incident" of a fair—*i. e.*, they were illegal unless specially granted in the patent, or recognized by custom. As a rule, they were paid only by the vendee, and to the market clerk, whose record of the payment was an attestation to the genuineness of the purchase. By 2 and 3 Philip and Mary c. 7 every lord of a fair entitled to exact tolls was bound to appoint a clerk to collect and enter them. It was also this functionary's business to test measures and weights. Tolls, again, are sometimes held to include "stallage" and "picage," which mean respectively the price for permission to erect stalls and to dig holes for posts in the market grounds. But toll proper belongs to the lord of the market, whereas the other two are usually regarded as the property of the lord of the soil. The law also provided that stallage might be levied on any house situated in the vicinity of a market, and kept open for business during the legal term of the said market. Among recent statutes, one of the chief is the Markets and Fairs Clauses Act (10 Vict. c. 14), the chief purpose of which is to consolidate previous measures. By the Act no proprietors of a new market are permitted to let stallages, take tolls, or in any way open their grounds for business, until two justices of the peace have certified to the completion of the fair or market. After the opening of the place for public use, no person other than a licensed hawker shall sell anywhere within the borough, his own house or shop excepted, any articles in respect of which tolls are legally exigible in the market. A breach of this provision entails a penalty of forty shillings. Vendors of unwholesome meat are liable to a penalty of £5 for each offence; and the "inspectors of provisions" have full liberty to seize the goods and institute proceedings against the owners. They may also enter "at all times of the day, with or without assistance," the slaughter-house which the undertaker of the market may, by the special Act, have been empowered to construct. For general sanitary reasons, persons are prohibited from killing animals anywhere except in these slaughter-houses. Again, by 36 and 37 Vict. c. 37, times of holding fairs are determined by the secretary of state; while 34 Vict. c. 12 empowers him to abolish any fair on the representation of the magistrate and with the consent of the owner. The preamble of the Act states that many fairs held in England and Wales are both unnecessary and productive of "grievous immorality."

The Fair Courts.—The Piepowder Courts, the lowest but most expeditious courts of justice in the kingdom, as Chitty calls them, were very ancient. The Conqueror's law *De Emporiis* shows their pre-existence in Normandy. Their name was derived from *pied puldreux*, Norman for peddler.[1] The lord of the fair or his representative was the presiding judge, and usually he was assisted by a jury of traders chosen on the spot. Their jurisdiction was limited by the legal time and precincts of the fair, and to disputes about contracts, "slander of wares," attestations, the preservation of order, etc.

Authorities.—See Herbert Spencer's *Descriptive Sociology*, 1873, especially the columns and paragraphs on "Distribution;" Prescott's *History of Mexico*, for descriptions of fairs under the Aztecs; Giles Jacob's *Law Dictionary*, London, 1809; Joseph Chitty's *Treatise on the Law of Commerce and Manufactures* (vol. ii. chap. 9), London, 1824; Holinshed's and Grafton's *Chronicles*, for lists, etc., of English fairs; Meyer's *Das Grosse Conversations Lexicon*, 1852, under "Messen;" article "Foire" in Larousse's *Dictionnaire Universelle du XIX*^{e}*. Siècle*, Paris, 1866–1874, and its references to past authorities; and especially the second volume, commercial series, of the *Encyclopédie Méthodique*, Paris, 1783; M'Culloch's *Dictionary of Commerce*, 1869–1871; Wharton's *History of English Poetry*, pp. 185, 186, of edition of 1870, London, Murray & Son, for a description of the Winchester Fair, etc.; a note by Professor Henry Morley in p. 498, vol. vii. *Notes and Queries*, second series; the same author's unique *History of the Fair of St. Bartholomew*, London, 1859; Wharton's *Law Lexicon*, Will's edition, London, 1876; and also, for some effects of recent legislation, as regards meat and fat stock markets, the debates in the House of Lords, Feb. 12 and Mar. 5, 1878. (J. MA.)

---

[1] Skene has shown the identity in Scotch borough law between "marchand travelland" and "pied puldreux," or "dusty fute."

FAIRBAIRN, Sir William, Baronet (1789–1874), a distinguished mechanical engineer, was born at Kelso, Roxburghshire, February 19, 1789. His father, who occupied the humble position of farm bailiff, possessed a large measure of the untiring energy and practical skill which were so conspicuously manifested in the son, but on account of adverse circumstances the family were often reduced to very hard straits; and as they frequently required to change their place of residence, the education which the children received was somewhat fragmentary. At the age of ten, however, young Fairbairn had "mastered the rules of arithmetic as far as practice and the rule of three," and had acquired a taste for reading by a perusal of the selections from English authors in Scott and Barrow's collections. He afterwards received additional instruction in reading, writing, and accounts, and obtained from his uncle, who was a parish schoolmaster, some knowledge of mensuration; but "the want of a good grammatical course, and a slight knowledge of the classics," was a frequent subject of regret to him in his subsequent life. Other circumstances worthy of notice connected with his earlier years were his fondness for athletic exercises, which often tempted him to the performance of daring feats in climbing, and the early development of his mechanical genius, which first displayed itself in the construction of a wagon to save himself the trouble and fatigue of carrying his infant brother on his back. It is somewhat remarkable that the other efforts of his mechanical genius in boyhood had reference chiefly to ships and mills, with the construction of both of which his name was subsequently so largely associated. In 1803 it was found necessary that Fairbairn should contribute something to the very straitened family income, and he obtained work at three shillings a week as a mason's laborer on the Rennie bridge at Kelso; but a serious accident which happened to him a few days after beginning this employment not only deprived the family of the small help of his earnings, but, by the expense it entailed, contributed to bring them almost to the brink of starvation. His father having, however, shortly after this obtained the situation of steward on a farm connected with Percy Main Colliery near North Shields, William obtained employment as a carter in connection with the colliery. Here, on account of his "Scotch accent and different manner, he became the mark of every species of annoyance," and had to take part in no less than seventeen pugilistic encounters before he was "able to attain a position calculated to ensure respect." In March, 1804, an immense change for the better occurred in his surroundings and prospects, by his being bound an apprentice to a millwright at Percy Mains. He now commenced a systematic course of self-improvement, assigning each day of the week to a particular subject of study, and devoting also a fixed amount of his time to recreation and amusement. Besides obtaining by unaided application a pretty complete knowledge of practical mathematics, he contrived to go through an extensive course of general reading; and an attachment he formed for a young girl, whom he afterwards married, by leading him to begin letter writing, was his first stimulus to the practice of literary composition. It was at Percy Mains also that he made the acquaintance of George Stephenson, who then had charge of an engine at a neighboring colliery, and the friendship thus begun lasted through life.

For some years subsequent to the expiry of his term of apprenticeship, Fairbairn, who, with all his forethought and persevering diligence, had still in his composition a strong love of adventure and a spice of recklessness, lived a somewhat roving life, seldom remaining long in one place and often reduced to very hard straits before he got a job. But soon after his marriage he began seriously to set himself to the attainment of the object he had long contemplated, his emancipation from daily labor; and in November, 1817, he entered into partnership with a shopmate of the name of Lillie, with whose aid he hired an old shed in High Street, Manchester, where he set up a lathe, and began business. His first order was to renew the shaftwork of an extensive cotton mill, which with great diligence he accomplished within the specified time, and not only satisfactorily, but with the substitution of improvements which virtually amounted to a revolution of the whole system of mill construction. Such a successful performance of their first contract immediately secured to the new firm a great reputation, and orders pressed in much faster than they were able with their limited capital to execute them. Their fame soon extended beyond Manchester, and in 1824 Fairbairn was engaged to plan and execute a new arrangement of the water-power of Catrine cotton works, Ayrshire, where, and at Deanston, Perthshire, he introduced a system of water-wheel construction whose hydraulic power has never been surpassed. In the summer of 1824 he also effected similar improvements in a mill at Zurich, Switzerland. In 1832 Fairbairn dissolved partnership with Lillie, retaining the works in Canal Street to which they had previously removed. In 1830 he had been employed by the Forth and Clyde Canal Company to make experiments with the view of determining whether it were possible to construct steamers capable of traversing the canal at a speed which would enable the canal interest to compete successfully with that of the railway; and the results of his investigations were published by him in 1831, under the title *Remarks on Canal Navigation*. His plan of using iron boats proved inadequate to overcome the difficulties of his problem, but it first suggested the construction of iron vessels; and in the development of the use of this material both in the case of merchant vessels and men-of-war the chief merit must be assigned to Fairbairn. In this way also he was led to pursue those experiments in regard to the strength of iron, according to its combination with other substances, and to various methods of preparation and construction, which have given him a place in this branch of mechanical engineering altogether pre-eminent. In 1835 Fairbairn established, in connection with his Manchester business, a ship-building yard at Millwall, London, where he constructed several hundred vessels, including many for the royal navy; but he ultimately found it impossible with his other engagements to superintend the work in such a satisfactory manner as to make it pay, and at the end of 14 years he disposed of the concern at a great loss. In 1837 he was employed by the sultan of Turkey with the view of assisting in the introduction of the mechanical arts into that country, and after his return home his services were rewarded by a decoration. For several years Fairbairn was engaged, in conjunction with Eaton Hodgkinson, in making experiments on the strength and other properties of iron, and in 1845 he was consulted by Robert Stephenson in reference to the best method of constructing the tubular bridge which the latter designed for carrying the railway across the Conway and Menai Straits. Although the share Fairbairn had in the undertaking has been the subject of some dispute, there can be no doubt that he was guided in his experiments chiefly by his own independent judgment, and that he was the inventor of the rectangular self-supporting tube which was the essential feature of the construction. For this invention he, with the concurrence of Stephenson, took out a patent, and he afterwards constructed more than a thousand bridges on the same principle. In reference to his connection with the invention, he published a volume entitled *An Account of the Construction of the Britannia and Conway Tubular Bridges*, etc., 1849. In 1849 he was invited by the king of Prussia to submit designs for the construction of a bridge across the Rhine, but after various negotiations, another design, by a Prussian engineer, which was a modification of Fairbairn's, was adopted. Another matter which engaged much of Fairbairn's attention was steam boilers, in the construction of which he effected many improvements. He is also the inventor of the tubular crane, and took out several patents for the construction and arrangement of steam machines. In 1851 he greatly aided, by his fertility and readiness of invention, in an investigation carried on at his works by Mr. Joule and Sir William Thomson in reference to the properties of the materials of the earth's surface; and from 1861 to 1865 he was employed to guide the experiments of the Government committee appointed to inquire into the "application of iron to defensive purposes." The results of his experiments were published in the proceedings of the committee. Fairbairn was a member of many learned societies both British and foreign. In 1860 he received the degree of LL.D. from the university of Edinburgh, and in 1862 that of D.C.L. from the university of Cambridge. He declined the honor of knighthood in 1861, but accepted a baronetcy in 1869. He died at Moor Park, Surrey, August 18, 1874. Perhaps no one ever made more use than Fairbairn of the time at his disposal, for amid all the cares of business he not only found leisure for varied scientific investigation, but managed to obtain a wide acquaintance with general literature, to conduct an extensive correspondence on a great variety of subjects, and also to participate largely in the delights of social intercourse. In private his unassuming but dignified simplicity, his thorough honor, and his geniality and kindness secured him general esteem. The results he achieved in mechanical science were due chiefly to minute, patient, and sagacious observation and experiment. It was his habit to aid himself in his investigations by committing his ideas to writing, and, when his opinions on any subject were matured, to communicate them to the world either in a published volume, or by a paper read before some learned institution. By his extensive acquaintance with English authors, and his early and patient practice of composition, he acquired the possession of a clear, simple, and nervous style, and his writings are in this respect worthy to be regarded as models in their own species of literature.

Among his principal writings, besides those already mentioned, may be named *On the application of Cast and Wrought Iron to Building Purposes*, 1856; *Iron, its History, Properties, and Processes of Manufacture* (reprinted from the eighth edition of the *Encyclopædia Britannica*), 1861; *Treatises on Mills and Millwork*, part i., 1861, part ii., 1863; *Treatise on Iron Shipbuilding*, 1865; and *An Experimental Enquiry into the Strength, Elasticity, Ductility, and other Properties of Steel*, 1869. These have all passed through several editions. His papers read before learned societies are too numerous to be mentioned. The *Life of Sir William Fairbairn*, partly written by himself, and edited and completed by William Pole, F.R.S., was published in 1877, and a popular edition of this work appeared in 1878.

FAIRFAX, **Edward** (? 1580–1632), the most poetical of all the translators of Tasso, was a native of Yorkshire, second son of Sir Thomas Fairfax of Denton. As Roger Dodsworth, the antiquary—a contemporary of Fairfax—styles him the "natural" son of Sir Thomas, it has been assumed that the poet was illegitimate, but it is certain that in the time of Queen Elizabeth the term "natural" was often used to signify *true* or *legitimate*, *i.e.*, the father's *own* son. We may therefore conclude with Douglas in his *Peerage* that Edward was the lawful son of Sir Thomas Fairfax, by Dorothy his wife, daughter of George Gale of Ascham Grange. The date of his birth has not been ascertained. He is said to have been only about twenty years of age when he published his translation of the *Gerusalemme Liberata*. This is very doubtful, but it would place his birth about the year 1580. He seems early to have preferred a life of study and retirement to the military service in which his brothers were distinguished. Having married, he lived at Fuystone, a place situated between the paternal seat of Denton and the forest of Knaresborough, and there his time was spent in his literary pursuits, and in the education of his children and those of his elder brother, Sir Thomas Fairfax, afterwards baron of Cameron. His famous translation appeared in 1600,—*Godfrey of Bulloigne or the Recoverie of Ierusalem, done into English heroicall verse by Edw. Fairefax, Gent.* Never did any mere translation receive such enthusiastic and continued approbation as this work by Fairfax. In the same year in which it was published extracts from it were printed in *England's Parnassus*. Edward Phillips, the nephew of Milton, in his *Theatrum Poetarum*, a work in which, as Wharton says, may be discovered many traces of Milton's hand, warmly eulogized the translation. Waller said he was indebted to it for the harmony of his numbers. Dryden places the translator almost on a parity with Spenser (whom undoubtedly Fairfax imitated), and Collins has beautifully associated him with his great original, Tasso:—

> "How have I sat, when piped the pensive wind,
> To hear his harp by British Fairfax strung!
> Prevailing poet, whose undoubting mind
> Believed the magic wonders which he sung!"[1]

In more recent times we find Campbell pronouncing Fairfax's work one of the glories of the reign of Elizabeth, to whom it was dedicated. Hallam, more critical, said the translation did not represent the grace of its original, and deviated too much from its sense, yet was by no means deficient in spirit or vigor. The poetical spirit of the work is indeed its life blood and preservation. Hoole and Hunt may give a more literal version, but Fairfax alone seizes upon the poetical and chivalrous character of the poem. As Denham says of Fanshawe's rendering of the *Pastor Fido*:—

> "They but preserve the ashes, he the flame,
> True to its sense, but truer to its fame."

And in this way he carries along with him the interest and admiration of the reader. The sweetness and melody of many passages are scarcely excelled even by Spenser. Fairfax made no other appeal to the public. He wrote, however, a series of eclogues, ten in number, one of which, the fourth, was published by permission of the family, in Mrs. Cooper's *Muses' Library* (1737). He wrote also a *Discourse on Witchcraft, as it was acted in the Family of Mr. Edward Fairfax of Fuystone in the county of York in 1621*, which was edited from the original copy by Mr. Monckton Milnes (now Lord Houghton) in the *Miscellanies of the Philobiblon Society*, 1858–9. Fairfax was a firm believer in witchcraft. He fancied that some of his children had been bewitched, and he had the poor wretches whom he accused brought to trial, but without obtaining a conviction. Such "follies of the wise" are painful to contemplate. Fairfax, however, only shared in the common superstition of the age, and it is at once a memorable and melancholy fact that Sir Matthew Hale, the most upright and able of lawyers, condemned two women to the stake on a charge of witchcraft. Fairfax described himself as "neither a fantastic Puritan nor superstitious Papist; but so settled in conscience as to have the sure ground of God's word to warrant all he believed, and the commendable ordinances of the English Church to approve all he practised." And he adds, "I live a faithful Christian and an obedient subject, and so teach my family." His descendants have not deemed it necessary to publish his writings on theological subjects and the keen controversies of the times. His fame is secure, grafted on the stem of Tasso, and flourishing in perennial beauty and vigor. Fairfax was living in 1631, and is supposed to have died soon afterwards, about 1632. (R. CA.)

FAIRFAX, **Thomas, third Lord**, better known as Sir Thomas Fairfax, the eminent Parliamentary general and commander-in-chief during the civil wars, was the eldest son of Sir Ferdinando (afterwards Lord) Fairfax by Mary, daughter of Lord Sheffield, president of the North, and was born at Denton, on the banks of the Wharfe, near Otley, Yorkshire, on the 17th of January, 1611–12. He studied at St. John's College, Cambridge, about four years (1626–30), and then proceeded to Holland to serve as a volunteer with the English army in the Low Countries under Lord Vere of Tilbury. This connection led to one still closer; in the summer of 1637 Fairfax married Anne, daughter of Lord Vere, a lady of spirit, whom Mr. Carlyle characterizes as "a Vere of the fighting Veres and given to Presbyterianism." The Fairfaxes, though serving at first under Charles I., were opposed to the arbitrary prerogative of the crown, and Sir Thomas (he had been knighted by Charles in 1640) declared that "his judgment was for the parliament as the king and kingdom's great and safest council." When Charles endeavored to raise a guard for his own person at York, intending it, as the event afterwards proved, to form the nucleus of an army, Fairfax was employed to present a petition to his sovereign, entreating him to hearken to the voice of his parliament, and to discontinue the raising of troops. This was at a great meeting of the freeholders and farmers of Yorkshire convened by the king on Heyworth Moor near York. Charles evaded receiving the petition, pressing his horse forward, but Fairfax followed him and placed the petition on the pommel of the king's saddle. The incident is typical of the times and of the actors in the scene. War broke out, Lord Fairfax was appointed general of the Parliamentary forces in the north, and his son Sir Thomas was made general of the horse under him. Both father and son distinguished themselves in the campaigns in Yorkshire. At first the Parliamentary troops were not successful. The Cavalier spirit of honor and high-bred loyalty was too much, as Cromwell said, for poor tapsters and town-apprentice people. There was little hope of success until men of strong religious feelings could be brought into the field against them, and this was effected by Oliver and his Ironsides, his invulnerable troop of disciplined horsemen. In the beginning of 1644 the Scottish army under the command of the earl of Leven joined the Parliamentary forces, and after some minor engagements, commenced the siege of York, then invested by the marquis of Newcastle. York was considered the second town of England, and upon its preservation Charles believed that the safety of his crown mainly depended. There were several assaults and sallies, but news having arrived that Prince Rupert was marching to raise the siege with 20,000 men, the besieging generals, Leven, Fairfax, and Manchester, resolved to draw off their troops, and encamp on the moor seven miles west of York. On the 2d of July, 1644, was fought the important battle of Marston Moor, which virtually decided the fate of the war. The gallantry of the troopers led by the old earl of Leven, Manchester, and Fairfax was conspicuous.[1] Fairfax was severely wounded, and he lost a brother in the action. The victory was so decisive that the marquis of Newcastle fled the kingdom. and the Royalists abandoned all hope of retrieving their affairs. The city of York was taken, and nearly the whole north submitted to the parliament.

---

[1] *Ode on Popular Superstitions.* Sir Walter Scott conceived that the lines applied to Fairfax (*Demonology*, Letter viii.), and Thomas Campbell seems to have entertained the same opinion (*Specimens of the Poets*),—also Charles Knight and others. A careful perusal of the stanza, however, will show that Collins intended the honor for Tasso, not for his translator. Both, indeed, may be said to have "believed the magic wonders which they sung."

In the south and west of England, however, the Royalist cause was still active. The war had lasted two years, and the nation began to complain of the contributions that were exacted and the excesses that were committed by the military. Dissatisfaction was expressed with the military commanders, Essex and Manchester, and as a preliminary step to reform, the self-denying ordinance was passed. This Act took from all members of parliament their commands in the army or their civil employments. The earl of Essex was removed from the supreme command, and Sir Thomas Fairfax appointed his successor. Cromwell, as a member of the House of Commons, was excluded by the ordinance, but he was too important to be dispensed with; he was made lieutenant-general under Fairfax. The army was new modelled, incompetent officers were dismissed, and the regiments completed by more select levies. The hostile armies met on the 14th of June, 1645, at Naseby in Northamptonshire, and a decisive battle took place, which ended in the total discomfiture of the Royalists. The king himself was in the field. "At Naseby," says Carlyle, "Charles fought his last battle—dashed fiercely against the new model army which he had despised till then—and saw himself shivered utterly to ruin"—partly through the fiery rashness of Prince Rupert, but mainly through the able generalship of Fairfax and Cromwell. The king fled to Wales. Fairfax besieged Leicester, and was successful at Taunton, Bridgewater, and Bristol. The whole west was soon reduced to obedience. The king had returned from Wales and established himself at Oxford, where there was a strong garrison, but danger was too apparent; the vacillating monarch withdrew secretly, and proceeded to Newark to throw himself into the arms of the Scots. Oxford capitulated; and by the end of September Charles had neither army nor garrison in England.

Fairfax arrived in London on the 12th of November, 1645. In his progress towards the capital he was accompanied by applauding crowds. Complimentary speeches and thanks were presented to him by both houses of parliament, along with a jewel of great value set with diamonds, and a sum of money. Charles was 'delivered up to the commissioners of parliament by the Scots in January, 1646. He had voluntarily surrendered himself to the Scots army, and they negotiated with the parliamentary leaders in his favor. There was a debt of £600,000, arrears of pay, owing to the Scots, but they agreed to take £400,000, one half of which was to be paid before the army left England. The bargain was concluded some months before there was any stipulation to deliver up the king, but probably, as Hallam remarks, the parliament would never have actually paid the money on any other consideration than the delivering of the king's person.[2] The transaction was naturally seized upon by the Royalists and the Cavalier wits and poets as a subject of obloquy and reproach to the Scots commissioners, and, by implication, to the whole Scottish nation. It is not yet forgotten. Such political libels are not of that class which the poet says are "born to die." They become the Shibboleths of a party, and descend from generation to generation.

Charles was delivered up to the commissioners of parliament on the 30th January, 1646–7. Fairfax, who preceded the king, having met him beyond Nottingham, dismounted from his horse, kissed the royal hand, and having resumed his seat, discoursed with the unfortunate prince during the journey to Holdenby. "The general," said Charles, "is a man of honor, and keeps his word which he had pledged to me." His chivalrous courtesy is of a piece with his whole character.

The agitation in the army now became formidable, and threatened anarchy. The Independents were too powerful for both parliament and Presbyterians. Fairfax resolved to resign his commission as commander-in-chief, but he was persuaded to retain it, and was passive, if not co-operating, in all the proceedings of the army which had for their object to destroy the power of parliament. Lord Ferdinando Fairfax died in the spring of 1647, and Sir Thomas succeeded to his title and to his office as governor of Hull. A second civil war broke out in the summer of 1648; a Scots army of 40,000 was raised to deliver the king from the "sectaries;" there were tumults in England and in Wales. Fairfax displayed the greatest activity in putting down these insurrections, and took Colchester, whither the royalist army had betaken themselves. It was at this time, when the commander-in-chief was besieging Colchester, that Milton addressed to him the sonnet:—

> "Fairfax, whose name in arms through Europe rings,
> Filling each mouth with envy or with praise."

The poet eulogizes the brave soldier for "firm unshaken virtue," but he hesitated to go along with the army and Independents in the trial of the king. He was placed at the head of the judges before whom Charles was arraigned, but he refused to act. In calling over the court, when the crier pronounced the name of Fairfax, a lady in the gallery called out "that the Lord Fairfax was not there in person, that he would never sit among them, and that they did him wrong to name him as a commissioner." This was Lady Fairfax, who could not forbear, as Whitelock says, to exclaim aloud against the proceedings of the High Court of Justice. The decision of the court was a grievous error. "When living, Charles was a baffled tyrant," as Lord John Russell has remarked; "when dead, he became a royal martyr." In June, 1650, after the Scots had declared for Charles II., the council of state resolved to send an army to Scotland in order to prevent an invasion of England. Fairfax declined to act against the Presbyterian Scots, and resigned his commission. Cromwell was appointed his successor, "captain-general and commander-in-chief of all the forces raised or to be raised by authority of parliament within the commonwealth of England." Fairfax received a pension of £5000 a year, and is no more heard of till after the death of the triumphant Protector.

When Monk invited him to assist in the operations about to be undertaken against Lambert's army he promptly obeyed the call, and in December, 1659, appeared at the head of a body of Yorkshire gentlemen; and such was the influence of Fairfax's name and reputation that the Irish brigade, consisting of 1200 horse, quitted Lambert's colors and joined him. This was speedily followed by the breaking up of all Lambert's forces, and that day secured the restoration of the monarchy. A "free" parliament was called; Fairfax was elected member for Yorkshire, and was put at the head of the commission appointed by the House of Commons to wait upon Charles II. at the Hague and urge his speedy return. Of course the "merry monarch, scandalous and poor," was glad to obey the summons, and Fairfax provided the horse on which Charles rode at his coronation. The remaining eleven years of the life of Lord Fairfax were spent in retirement at his seat in Yorkshire. He must, like Milton, have been sorely grieved and shocked by the scenes that followed—the brutal indignities offered to the remains of his companions in arms, Cromwell and Ireton, the sacrifice of Sir Harry Vane, the neglect or desecration of all that was great, noble, or graceful in England, and the flood of immorality which, flowing from Whitehall, sapped the foundations of the national strength and honor. Lord Fairfax died at Nunappleton on the 12th of November, 1671. The integrity of Fairfax has never been doubted. No one has ever attempted to charge meanness or corruption on the Parliamentary general. But he was great only in the field, and had apparently none of the qualities of a statesman. He is placed at great disadvantage, however, by being both in war and in peace overshadowed by his associate Cromwell:

---

[1] Cromwell, in the letter to his brother-in-law, assumes the whole credit of the defeat of the Royalist right, certainly at the expense both of truth and honor. He says: "The left wing which I commanded, being our own horse, saving a few Scots in our rear, beat all the Prince's horse. God made them as stubble to our swords." Now the few Scots consisted of 1920 men out of 4200, and Cromwell's assertion that they were in the rear is contradicted by every other eye-witness who mentions them. Principal Bailie, who received a long account of the battle from his namesake, and had other sources of information now lost, says that David Leslie (Leven) in all places that day was Cromwell's leader.—Markham's *Life of Fairfax*. Mr. Carlyle does not take up this disputed point.

[2] Major-General Skippon carried up the cash, £200,000, to Newcastle successfully in a proper number of wagons; got it all counted there, bags of £100, chests of £1000 (5–19th January, 1646–7), after which the Scots marched peaceably away.—*Carlyle.*

> "And under him
> His genius was rebuked, as, it is said,
> Mark Antony's was by Cæsar."

Lord Fairfax had a taste for literature. He translated some of the Psalms, and wrote poems on solitude, the Christian warfare, the shortness of life, etc., none of which are above mediocrity. During the last year or two of his life he wrote two *Memorials* which have been published—one on the northern actions in which he was engaged in 1642–44, and the other on some points during his command in the army. At York and at Oxford he endeavored to save the libraries from pillage, and he enriched the Bodleian with some valuable MSS. His correspondence was published in 1848–9 in four volumes, and a life of him by Clements R. Markham in 1870. (R. CA.)

FAIRFIELD, a town and port of entry of Fairfield co., Connecticut, is situated near Long Island Sound, and on the New York and New Haven railroad, 22 miles S.W. of New Haven. It consists chiefly of one spacious street of new and handsome buildings. The beautiful scenery and fine sea air of the neighborhood attract to the town a considerable number of summer visitors, but its prosperity depends chiefly on its shipping trade. About one and a half miles south-east from the town is Black Rock, one of the finest harbors of the state. Fairfield was settled in 1659. In 1779 it was burned by the British under Governor Tryon. The population in 1870 numbered 5645, but since then a portion of the town, containing more than a fourth of the inhabitants, has been annexed to Bridgeport.

FAIRHOLT, FREDERICK WILLIAM (1813–1866), a most industrious antiquary, draughtsman, and editor of our older literature, was born in London in the year 1813. His father, who was of a German family (the name was originally Fahrholz), was a tobacco manufacturer, and for some years Fairholt himself was employed in the business. He had, however, other aims. For a time he was a drawing-master, afterwards a scene-painter. Some pen and ink copies made by him of figures from Hogarth's plates led to his being employed by Charles Knight on several of that gentleman's illustrated publications. His first published literary work was a contribution to Hone's *Year-Book* in 1831. His life seems to have been one of almost uninterrupted quiet labor, carried on until within a few days of death. Several works on civic pageantry and some collections of ancient unpublished songs and dialogues were edited by him for the Percy Society in 1842. In 1844 he was elected fellow of the Society of Antiquaries. An edition of the dramatic works of Lilly was published by him in 1853. His principal independent works are *Tobacco, its History and Association*, 1859; *Up the Nile and Home Again*, 1862; many articles and serials contributed to the *Art Journal*, some of which were afterwards separately published, as *Costume in England*, 1846; *Dictionary of Terms in Art*, 1854. These works are illustrated by numerous cuts, drawn on the wood by his own hand. His pencil was also employed in illustrating Evan's *Coins of the Ancient Britons*, Madden's *Jewish Coinage*, Halliwell's folio *Shakespeare*, Roach Smith's *Richborough*, the *Miscellanea Graphica* of Lord Londesborough, and many other works. Mr. Fairholt was entirely a Londoner; born in London, and never out of sight of St. Paul's for the first twenty-two years of his life, he ever loved a paved street better than a green lane. His later years were much troubled by disease, which, though temporarily alleviated by a voyage to Egypt and Nubia with the present Lord Londesborough, terminated in consumption. He died April 3, 1866. His books relating to Shakespeare were bequeathed to the library at Stratford-on-Avon; those on civic pageantry (between 200 and 300 volumes) to the Society of Antiquaries; his old prints and works on costume to the British Museum.

FAIRIES (Fr., *fée, faerie;* Prov., *fada;* Sp., *hada;* Ital., *fata;* Med. Lat., *fatare*, to enchant, from Latin *fatum*, fate, destiny). In early times, when so much of the energy of man was not, as now, applied to practice, it seems to have found a natural outlet in the imagination. Of all the minor creations of mythology, the fairies are the most beautiful, the most numerous, the most memorable in literature. Like all organic growths, whether of nature or of the fancy, they are not the immediate product of one country or of one time; they have a pedigree, and the question of their ancestry and affiliation is one of wide bearing and weighty side-issues. But mixture and connection of races have in this, as in many other cases, so changed the original folk-product that it is difficult to disengage and separate the different strains that have gone to the making or moulding of the result as we have it. Certain points, however, in the course and development of the superstition can be definitely placed.

The character of the religion of the people of Gaul was undoubtedly much changed by the Roman occupation, but, in inscriptions and legends, traces are to be found of what the primitive belief was, which faintly shadow out that primitive belief, and it is here that we first find traces of one of the various classes of beings which have in later times received the general name of fairies. Votive inscriptions to supernatural beings, corresponding to the nymphs and fauns of classic mythology, have been found on Gaulish and German soil repeatedly. A passage in Pomponius Mela (*De Situ Orbis*, bk. iii. c. 6) points distinctly to a belief of the Bretons in certain beings having many characteristics of the fairies.

> "Sena being situate in the British sea against the country of the Osismyes is renowned with the oracle of the god of the Galles, whose vowesses, in number nine, are hallowed to continual virginitie. They call them Gallicens, and are of opinion that, through the singular wisdom wherewith they are indued, they raise the seas and winds with their charms, and transform themselves into what beastes they will, and heale such diseases as to others are incurable, and knowe things to come and prophesy of them, but not unto any other than such as sayle thither for the nonce, and come of set purpose to demaund counsell of them."—Golding's translation, p. 78.

The similarity of these beings to the fays that play so important a part in mediæval romances is remarkable. A passage in the romance of Lancelot du Lac is so directly descriptive that it may be quoted:—

> "En cellui temps estoient appellees fées toutes celles qui sentermet-toient den-chantements et de charmes, et moult en estoit pour lors principallement en la Grande Bretagne, et scavoient la force et la vertue des parolles, des pierres, et des herbes, parquoy elles estoient tenue en jeunesse et en beaulte et en grandes richesses comment elles divisoient. Et ce fut estably au temps de Merlin le prophete."—Ed. 1533, p. v.

These fays preside at the birth and influence the destiny of men, taking individuals under their special protection. They take lovers from among men, and are often described as of delicate, unearthly, ravishing beauty. The enjoyment of their charms is, however, generally qualified by some restriction or compact, the breaking of which is the cause of calamity to the lover and all his race, as in the notable tale of Melusine. This fay by enchantment built the castle of Lusignan for her husband. It was her nature to take, every week, the form of a serpent from the waist below. The hebdomadal transformation being once, contrary to compact, witnessed by her husband, she left him with much wailing, and was said to return and give warning by her appearance and great shrieks whenever one of the race of Lusignan was about to die. At the birth of Ogier le Dannois six fairies attend, five of whom give good gifts, which the sixth overrides with a restriction. Gervaise of Tilbury, writing early in the 13th century, has, in his *Otia Imperialia*, a chapter *De lamiis et nocturnis larvis*, where he gives it out, as proved by individuals beyond all exception, that men have been lovers of beings of this kind whom they call *Fadas*, and who did, in case of infidelity or infringement of secrecy, inflict terrible punishment—the loss of goods and even of life. There seems little in the charactistics of these fairies of romance to distinguish them from human beings, except their supernatural knowledge and power. They are not often represented as diminutive in stature, and seem to be subject to such human passions as love, jealousy, envy, and revenge. To this class belong the fairies of Boiardo, Ariosto, and Spenser.

The etymology traced at the beginning of this article is that generally given, but it is by no means universally accepted. Some fanciful theories that prevailed at the beginning of the century, as, for instance, that adopted by Sir W. Scott in his *Essay on the Fairy Superstition*, which connects the word fairy with the Persian *peri*, are now generally rejected. M. Walckenaer believed the word to be purely Celtic (see his *Lettres sur les Contes des Fées*, Paris, 1836). Apart, however, from the question of the origin and varying intention of the term, the kind of beings first signified by it can be fairly connected with creatures of the Greek and Roman mythology.

The Gauls had no doubt a populous pantheon. The peasants seem to have offered worship to, and peopled the old hills, trees, rocks, streams, and springs with, beings similar to the nymphs and fauns of antiquity. And each little locality seems to have had its protecting deities, female, and generally three in number. The coming of Christianity only changed slightly the way of regarding these creatures—did not by any means overcome the superstition. It is most likely to the similarity in character and function of these local deities to the Parcæ or Fates of antiquity that we owe the name generally given to all the different beings, a great part of whose functions it was to preside at the birth and rule the destiny of man. It seems probable that among the people generation after generation of nurses changed these topical divinities into those fairies, the tales of which Perrault and his successors made so popular. The fairy tales in the *Piacevoli Notte* of Straparola (1550–54) and the *Pentamerone* of Basile (1672) are also, no doubt, the results of genuine tradition. By this time, however, the influence of Eastern stories had been brought by travellers and crusaders to bear upon the traditions of the West, as well as that of the superstition next to be mentioned. To the elves and duergar of the northern mythology we must go for the origin of those little creatures that dance in the woods and meadows. The elves are divided into two classes, the light and the dark. It is related in the prose Edda that the gods reflected how the duergar animated the clay below the earth like maggots in flesh; and certainly, under different names, as brownie, cluricaune, kobbold, nisse, lutin, hobgoblin, beings of this kind, whether of the hill or wood, of the rock or stream, or of the household, have played a great part in the life of the peasantry of many countries. They are represented as of very various characteristics and propensities. Their appearance and power are sometimes propitious, at other times baleful. "He that looks on them shall die," says Falstaff, and hides his face accordingly. Perhaps the leading features of their character with relation to man is a desire for fair human children, which, substituting abortive creatures, they practise many tricks to obtain. They are often represented as animated by a spirit of malicious mockery towards men, which is not, however, altogether malignant. In connection with their fabled abode underground, it is to be noted that Chaucer makes Pluto and Proserpina king and queen of faery.

Besides scattered allusions, we owe to this superstition many fair products of our poetry. Works of Drayton, Ben Jonson, Fletcher, Randolph, and Herrick will at once suggest themselves. Its influence is of course very marked in the youthful works of Milton. Of the *Midsummer Night's Dream*, that perfect rose among all these flowers of fancy, it is unnecessary to speak, even were it possible to do so adequately.

For an elaborate account of fairies in general, see Keightley's *Fairy Mythology*, where the legends of different countries are collected. (W. HE.)

FAITHORNE, William, a painter and engraver was born in London, at what date is uncertain, but most probably either in 1626 or 1627. He was apprenticed to Robert Peake, a painter and printseller, who received the honor of knighthood from Charles I. On the outbreak of the civil war he accompanied his master into the king's service, and being made prisoner at Basinghouse, he was confined for some time to Aldersgate, where, however, he was permitted to follow his profession of engraver, and among other portraits did a small one of the first Villiers, duke of Buckingham. At the earnest solicitation of his friends he very soon regained his liberty, but only on condition of retiring to France. There he was so fortunate as to receive instructions from Robert Nanteuil, by which his style was greatly benefited. He was permitted to return to England about 1650, and took up a shop near Temple Bar, where, besides his work as an engraver, he carried on a large business as a printseller. In 1680 he gave up his shop and retired to a house in Blackfriars, occupying himself chiefly in painting portraits from the life in crayons, although still occasionally engaged in engraving. He died of a lingering consumption, May 13, 1691; and it is said that his life was shortened by the misfortunes, dissipation, and early death of his son William. Faithorne is especially famous as a portrait engraver, and among those on whom he exercised his art were a large number of eminent persons, including Sir Henry Spelman, Oliver Cromwell, Henry Somerset, the marquis of Worcester, John Milton, Queen Catherine, Prince Rupert, Cardinal Richelieu, Sir Thomas Fairfax, Thomas Hobbes, Richard Hooker, Robert second earl of Essex, and Charles I. All his works are remarkable for their combination of freedom and strength with softness and delicacy, and his crayon paintings unite to these the additional quality of clear and brilliant coloring. Faithorne is the author of a work on engraving, which was published in 1722.

FAITHORNE, William (1656–1686), a mezzotinto engraver, son of the former, was born in 1656. He had the advantage of his father's instructions, and devoting his attention chiefly to mezzotinto, at an early age gave promise of attaining great excellence, but became idle and dissipated, and it is said involved his father in money difficulties. Among persons of note whose portraits he engraved are Charles II., Mary princess of Orange, Queen Anne when princess of Denmark, and Charles XII. of Sweden. He died in 1686.

The best account of the Faithornes is that contained in Walpole's *Anecdotes of Painting*. A life of Faithorne the elder is preserved in the British Museum among the papers of Mr. Bayford, librarian to Lord Oxford, and an intimate friend of Faithorne.

FAIZÁBÁD, a division or commissionership of Oudh in British India, now under the jurisdiction of the lieutenant-governor of the North-Western Provinces. It lies in 26°–28° 30′ N. lat. and 81° 5′–83° 15′ E. long., and comprises the three districts of Faizábád, Gondá, and Bharaich. It is bounded on the N. by the independent state of Nepál, on the E. by Gorakhpur district, on the S. by Azimgarh and Sultánpur, and on the W. by Bára Banki, Sitápur, and Kheri. Population, according to the census of 1868—Hindus, 3,028,502; Mahometans and others, 350,760; total, 3,379,262, of whom 1,747,411 were males and 1,631,851 females. Number of villages or townships, 8452. Area, 7671 square miles.

Faizábád, a district of British India in Oudh, under the lieutenant-governor of the North-Western provinces, in 26°–27° N. lat. and 81°–82° E. long., is bounded on the N. and E. by the Gogra river, on the S. by Azimgarh district, and on the W. by the Gumti river. The area, according to the latest estimate in 1877, is 1649 square miles, and the population 1,024,092 souls. Faizábád forms a very historical district, lying between the two great rivers of Oudh, and is interesting alike for its calamities and its ruins. Ajodhyá, the capital of the ancient kingdom of Oudh, which plays so conspicuous a part in the Sanskrit epics, lies in its northern angle, close to the present city of Faizábád. In more modern times the district was the centre of the nawáb vizier's influence, and contained his capital until the removal of his court to Lucknow in 1775. In 1857 it became the scene of the disaster described below. Since the mutiny, the district has settled down into a peaceful part of the British empire, with an increasing population. It is penetrated throughout its length from north to south by the Oudh and Rohilkhand railway, and does an important trade with the great cities of the north-west. The growth of its population has been the more marked, owing to the previous desertion and decay in the last century on the transfer of the nawáb's court to Lucknow. The population, classified according to religion, is—Hindus, 922,360, Mahometans, 100,410, Christians, 1322, of whom 1267 represent the European soldiers; total, 1,024,092; the density of population averaging 621 per square mile. The five largest towns, containing upwards of 5000 inhabitants, are—Faizábád, population, 37,804; Tánda, 13,543; Ajodhyá, 9949; Jalálpur, 6275; and Sajauli, 5614. The railway stations are the following:—Málipur, Akbarpur, Kánurpur, Gosáinganj, Tandauli, Belarghát, Darsinagar, Ajodhyá, Faizábád, and Sajauli. The estimated cultivated area in 1875 was 628,690 acres, of which rice was returned as occupying 162,562; wheat, 162,895; other food grains, 248,837; oil-seeds, 6888; sugar, 27,800; cotton, 492; opium, 4982; indigo, 6900; fibres, 202; tobacco, 3957; and vegetables, 3522. The total value of the trade of Faizábád in 1874–75 was exports £425,115, and imports £122,511, the chief articles of export being food grains, oil-seeds, country cloth, and silk, and cotton; and of imports, sugar, spices, European piece goods, etc. The revenue of the district in 1874–75 was £151,856, of which £133,243, or 85 per cent., was derived from the land-tax. The machinery for protecting person and property consisted of 15 magisterial and 15 civil and revenue courts. The regular police force consisted of 552 officers and men, maintained at a cost of £8363 out of the imperial revenue; a town and cantonment police numbering 237, and costing £1402 from local sources; and a village police numbering 2277 men, maintained by the villagers or landholders at a cost of £5524. The average daily number of prisoners in jail in 1875 was 791, or one to every 1294 of the population. The schools in the same year numbered 98, attended by 4461 pupils. Four charitable dispensaries afforded medical aid to 13,463 patients; and a poorhouse furnished assistance to 6752 paupers in the shape of food, clothing, and shelter.

Faizábád, the chief town and administrative head-quarters of the district of the same name, situated on the right or south bank of the Gogra, in 26° 47′ N. lat. and 82° 15′ E. long. Adjacent to Faizábád on the E., and now forming a suburb of the town, is Ajodhyá, the ancient capital of King Daswratha, the father of Ráma, the hero of the Rámáyaná. Of this ancient city, said to have covered an area of 48 *kos*, now hardly a trace remains. The modern Ajodhyá contains several Jain and Hindu temples. The city of Faizábád was founded about 1730 by Sa'adat Ali Khán the first nawáb vizier of Oudh, who made it his capital. The place rapidly grew in importance until 1775, when the court of Oudh was removed to Lucknow. It then rapidly decayed, all the leading merchants, bankers, etc., abandoning the place. In 1839, Butter estimated its population at 100,000, but fast diminishing, owing to the exactions and oppressions by the native officials of the nawáb's Government. At the time of the census in 1869 Faizábád contained only 37,804 inhabitants; but it is now again advancing in prosperity, and is rapidly becoming an emporium of trade. At the time of the annexation of Oudh in 1856 Faizábád was made, and still continues to be, a large military station. On the outbreak of the mutiny in 1857, the cantonment contained two regiments of infantry, a squadron of cavalry, and a light field battery of artillery—all natives. Owing to their threatening demeanor after the Meerut massacre, many of the European ladies and children were sheltered by one of the great landholders of Oudh, and others were sent forward to less disturbed parts of the country. The troops rose, as was anticipated, and although they at first permitted their officers to take boats and proceed towards Dinapur, a message was afterwards sent to a rebel force lower down the river to intercept the fugitives. Of four boats, one succeeded in reaching Dinapur safely, having passed the rebels unnoticed. Of the occupants of the other three boats, one person alone escaped. Faizábád is now a station for European as well as for native troops.
